Students will be admitted to this Examination after one Academical year from Matriculation.—Fee, £1.

Candidates at this Examination will be required to answer in the following subjects:—

I. Latin. II. Any one of the following languages, viz.: Greek, French, German, Italian, Spanish, Celtic, Sanskrit,

Hebrew, or Arabic. III. English language and Literature. IV. Mathematics. V. Experimental Physics.

The first period of Medical Study shall comprise—*a.* Chemistry, six months; *b.* Practical Chemistry, three months in a chemical laboratory; *c.* Botany, with Herborization for practical study, and Zoology; *d.* Anatomy and Physiology; *e.* Practical Anatomy; *f.* Materia Medica. The second period—*a.* Anatomy and Physiology, including Histology; *b.* Practical Anatomy; *c.* Theory and Practice of Surgery; *d.* Midwifery and Diseases of Women, six months; *e.* Theory and Practice of Medicine; *f.* Medical Jurisprudence.

Candidates are further required to have attended during the First period—Medical-Chirurgical, a winter of six months; and during the second period—Practical Midwifery, Midwifery Hospital, six months, or six months at a Midwifery Dispensary where similar clinical instruction is given (the certificate must state that the candidate has attended at twenty labours); Medico-Chirurgical Hospital, eighteen months, including either three winters, or two winters and two summers.

Candidates must also before the Degree Examination produce certificates—(1) of personal attendance on fever cases; (2) of having compounded under an apothecary or pharmaceutical chemist for at least three months; (3) of instruction in vaccination; (4) of having attended a course of lectures (not less than 25) and clinical instruction on Mental Diseases.

FIRST UNIVERSITY EXAMINATION IN MEDICINE.

The fee for this Examination is £1.

The subjects—*a.* Zoology; *b.* Botany; *c.* A Modern Language.

Candidates who have passed in a Modern Language at the ordinary First University Examination are exempt from presenting this subject.

SECOND UNIVERSITY EXAMINATION IN MEDICINE.

The Second University Examination in Medicine comprises the following subjects:—Anatomy, Physiology, Materia Medica, and Chemistry.

Before being admitted to this Examination, each student must produce satisfactory evidence of having completed the course recommended for study during the first period. Fee, £1.

EXAMINATION FOR THE M.B. DEGREE.

Fee, 3*l*. Each candidate must produce certificates of having completed all the prescribed courses.

The Examination comprises the subjects recommended for study during the second period, and includes Examinations in Clinical Medicine and Clinical Surgery.

EXAMINATION FOR THE M.CH. DEGREE.

Conferred only on graduates in Medicine of the University. Fee, 5*l*.

The Examination comprises Theory and Practice of Surgery, including Operative and Clinical Surgery.

EXAMINATION FOR THE DIPLOMA IN OBSTETRIC.

Conferred only on graduates in Medicine of the University. Fee, 2*l*. The Examination comprises Theory and Practice of Midwifery, and the use of obstetrical instruments and appliances.

EXAMINATION FOR THE DIPLOMA IN SANITARY SCIENCE.

Conferred only on graduates in Medicine of the University. Fee, 2*l*.

The Examination shall embrace the following subjects:—Climate, Chemistry, Geology, Physics; Vital Statistics: Hygiene, Sanitary Law.

The Examination in Chemistry shall include a practical part on the chemical and microscopical examination of air, water, food, poisonous substances used in manufacture, &c.

The Examination in Physics shall embrace the reading of plans, sections, scales, &c., in connection with buildings, sanitary construction, &c.

EXAMINATION FOR THE M.D. DEGREE.

Fee, 5*l*.

The degree of Doctor may be conferred on any candidate who has obtained the M.B., and has produced a certificate of having been for the last two years engaged in hospital or private medical or surgical practice, or in the military or naval medical service, provided that the candidate shall submit to the medical examiners a thesis composed by himself, and approved by them. No thesis will be approved

which does not contain some original or personal observations in Practical Medicine, Surgery, Midwifery, or in some of the sciences embraced in the curriculum, or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted.

Candidates settled for a period of two years in the colonies or foreign countries may, on satisfying the Senate to that effect, and complying with the conditions above described, have the degree conferred on them in absence.

THE COLLEGE OF SURGEONS' licence, or L.R.C.S.I., is universally sought for by those students who do not resort to a University. Great and important changes have been made in the system of granting these licences within the past year. Henceforth every candidate must pass four professional examinations—one at the end of each year of study—as follows:—*a.* Preliminary scientific; *b.* Preliminary professional; *c.* Theoretical; *d.* Practical. The preliminary scientific (*a*) may be studied for at home; the other examinations involve teaching in a medical school. The College holds the only extra-university preliminary examination, save that of the Apothecaries' Hall. It grants the higher qualification of Fellow, or F.R.C.S.I., to those who are specially qualified and specially examined for that diploma, and it also confers a midwifery diploma on examination by a special Court of Examiners.

As it is our business especially to provide information for the student who is about to commence his first year of study, we substitute the new scheme, *compulsory upon all students who commenced their studies after last July*, for the old regulations (which may be found in the Irish Medical Directory); but it is to be remembered that students who have already commenced medical study may present themselves either under the old or new system.

We call the special attention of students who intend taking the L.R.C.S.I. to the fact that, for the future, they *must* pass their preliminary examination, and register themselves at the Branch Medical Council, 35 Dawson Street, within fifteen days of the time at which they enter on medical study, otherwise their lecture and hospital certificates for courses commenced before they have done so will not count.

The Matriculation Examination of the Royal University and the pass in the requisite subjects at the Intermediate Examination are now recognised as equivalent preliminary examinations.

THE NEW SCHEME OF THE EDUCATION AND EXAMINATION FOR THE L.R.C.S.I.

Every candidate shall produce evidence—1. Of having, before entering on medical studies, passed the preliminary examination of the College, or an equivalent examination in general education, recognised by the General Medical Council; and 2. Of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised by the College if the date of commencement of the course to which the certificate refers is more than fifteen days prior to such registration.

This College recognises as the commencement of professional study:—

1. Attendance on the practice of a hospital, or other public institution recognised by the College for that purpose; or,

2. Instruction as pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council; or,

3. Attendance on lectures on anatomy, physiology, or chemistry, by lecturers recognised by this College.

The letters testimonial of the College shall not be granted to any candidate at an earlier period than forty-five months subsequent to his registration as a medical student; or to any one who has not attained the age of twenty-one years.

Registered Pupils of the College.—Any student may be registered as a pupil in the College books on payment of a registration fee of £5 5*s*., for which credit will be given subsequently in his examination fee. No student can be admitted as a candidate to examination until he shall have been so enrolled, and passed the preliminary examination.

Examinations.—Every candidate must pass a preliminary examination and four professional examinations. Candidates who possess a diploma or degree in either medicine or surgery, or who have passed a sufficient examination in these subjects, may be exempted from compliance with this rule.

Candidates must return their names, fees, and certificates one week before examination.

Preliminary Examination.—All students must pass their preliminary examination before entering upon their professional studies.

The preliminary examinations are held quarterly, viz., on the 3rd Wednesday in Jan., April, July, and Oct., in the following subjects, with permission to the student to select French, German, or Greek:—1. English, including grammar and composition; 2. Arithmetic, including vulgar and decimal fractions; 3. Algebra, including simple equations; 4. Geometry, first two books of Euclid; 5. Latin—the first and second Books of the *Æneid* of Virgil, or the *Jugurthine War* of Sallust, or the Third Book of Livy; 6. Physics, as may be found in Ganot's Popular Natural Philosophy. The examination in physics may be passed either at the preliminary or the first professional examination.

Alternative subjects—one to be selected by the student:—1. Greek—the Gospel of St. John, or the Dialogue of Lucian, entitled "Menippus or the Necromancy;" 2. French—Fénelon's "Télémaque;" 3. German—Schiller's "Wilhelm Tell."

Fees.—Registered pupils of the College free. Non-registered pupils, £1 1s. Rejected candidates, whether registered pupils or not, shall pay a further fee of £1 1s. for each re-examination.

Professional Examinations.—The 1st, 2nd, and 3rd professional examinations shall be held in the July and October of each year. Should the student fail to pass in July he may present himself at the examination held in October.

The examination of each year must be passed before a new session can be entered on.

First Professional Examination.—Candidates must, before admission to the first preliminary examination, produce evidence of having passed the preliminary examination, and of having been registered as students, and of having been engaged in study for at least nine months after registration.

Candidates are recommended to attend a course of lectures on practical anatomy, and one on chemistry, before this examination.

The examination shall include the following subjects, viz.:—1. Physic, if not passed at the preliminary examination; 2. The elements of chemistry, as may be found in Roscoe's *Lessons in Elementary Chemistry*, from chap. i. to xiii. inclusive; 3. Botany, as may be found in Oliver's *Lessons in Botany*, Part I., with descriptions of the following plants:—The butter-cup, poppy, pea, strawberry, fox glove, and dandelion; 4. Anatomy—human osteology; 5. Practical Pharmacy—Elementary.

Fees.—The fee for this examination shall be £5 5s., in addition to the registration fee of £5 5s. Neither of these fees shall be returned in case of rejection, but the candidate on paying an additional sum of £2 2s. shall be admitted to re-examination.

Second Professional Examination.—Candidates must produce evidence of having passed the first professional Examination, also certificates of having subsequently attended: Hospital, nine months; Winter Courses: Practical anatomy, with demonstrations and dissections; physiology; surgery; chemistry (unless attended in first year); Summer Courses, three months: Practical chemistry, practical physiology, materia medica.

Fees.—The fee for this examination shall be £5 5s. Candidates who are rejected will be admitted to re-examination on paying an additional fee of £2 2s.

Candidates shall be examined in: 1. Anatomy—bones, joints, muscles, and topographical anatomy of the viscera of the chest, abdomen, and pelvis; 2. Histology, and the physiology of the circulatory, respiratory, and digestive systems; 3. Surgery—The signs, terminations, and treatment of inflammation, wounds, hæmorrhage, burns and scalds, ulcers, and bandaging; 4. Chemistry; 5. Materia medica.

Third Professional Examination.—Candidates must produce evidence of having passed the second examination, also certificates of hospital; nine months as an extern pupil, or six months as a resident pupil. Winter Courses—Demonstrations and dissections, practical anatomy (unless attended

in the first year), surgery, medicine. Summer Course, three months—Medical jurisprudence.

Fees.—The fee for this examination shall be £5 5s.; and for re-examination, if rejected, £2 2s.

Candidates shall be examined in: 1. Anatomy; 2. Physiology; 3. Surgery, not including operative, clinical, and ophthalmic surgery, which are reserved for the final professional examination.

Fourth, and final Professional Examination.—The fourth examination shall be held in July and October, and in the following April. Candidates must produce evidence of having passed the third examination, also of having attended hospital nine months as extern pupil, or six months as resident pupil, unless a certificate to that effect has been accepted in the third year. Winter Courses—Dissections and demonstrations; midwifery, a midwifery hospital, or maternity, for six months, and of having been present at thirty labours. (May be attended in the third or fourth year, winter or summer.) Clinical ophthalmology, three months. (May be attended in the third or fourth year, winter or summer.) Operative surgery. Practical instruction in vaccination. (May be attended at any time after registration.)

Fees.—The fee for this examination shall be £5 5s.; and £2 2s. for re-examination, if rejected.

Candidates shall be examined in: 1. Surgery, clinical, ophthalmic, and operative, with surgical anatomy; 2. Medicine; 3. Midwifery and Diseases of Woman; 4. Medical Jurisprudence.

THE COLLEGE OF PHYSICIANS grants its licence, L.K.Q.C.P.—the usual medical qualification of the Irish student—which is almost always taken by the young surgeon immediately after his passing at the College of Surgeons, and for it the same curriculum of study is sufficient. The College has recently established a higher qualification of "Member," for which there is a special examination, and there is also the still higher grade of Fellow of the College, to which admission is by ballot, without examination or curriculum.

The cost of obtaining the L.R.C.S.I., with the L.K.Q.C.P.I., and the license in midwifery, is nearly as possible as follows:—

Lectures, &c.	£65	0	0
Hospital	36	0	0
Diploma fees, L.R.C.S.I. ...	26	5	0
Diploma fees, L.K.Q.C.P. ...	15	15	0
Diploma fees, Lic. Mid. ...	3	3	0
	£145	18	0

As a certificate of study in vaccination is now required, a course of clinical instruction in ophthalmology, and a course of attendance at a midwifery hospital is required for the midwifery diploma; the total expense of the Dublin double diploma may be set down at £155.

THE MEMBERSHIP.

I.—The grade of members is distinct from that of the fellows, and the members as such are not members of the Body Corporate.

II.—Members alone are eligible to the fellowship. They have the use of the reading rooms and library.

III.—Licentiates admitted before December 12th, 1878, are entitled to be admitted members of the College without payment or examination, on giving six weeks' notice, in writing, to the Registrar.

IV.—Every candidate for membership must produce evidence—

1. Of being over 25 years of age.

2. Of being a licentiate of the College for three years at least; or, a licentiate of one year's standing, if also graduate of arts; or, a licentiate of one year's standing, if also a registered practitioner of seven years' standing at the time of his obtaining the licence.

3. Of professional conduct and moral character.

4. That he is not engaged in trade; and that he does not directly or indirectly vend medicines or drugs; and that he does not dispense or compound medicines for anyone—even his own private patients—(except in cases of extreme urgency); nor practise medicine or surgery in partnership, by deed or otherwise. (Candidates for the membership by examination must, in addition to the above, show proof as follows):—

5. Of having attended courses in ophthalmology and histology.

6. Of having been for six months resident physician, or resident pupil, in a recognised hospital; or for same period as clinical clerk in the medical wards, or in medical charge, for at least twelve months, of any public institution for the treatment of the sick.

7. Of having paid the fee of twenty guineas.

V.—Every candidate must pass examination in the following subjects:—1. Principles of Medicine, including Pathology, Medical Anatomy, and Medical Chemistry. 2. Practice of Medicine, including Principles of Public Health. 3. Clinical Medicine.

Oral examination.—This examination includes the investigation of morbid specimens, the qualitative analysis of animal products, the detection of poisons, and the use of the microscope, as well as that in classics and modern languages.

LICENCES IN MEDICINE AND MIDWIFERY.

I.—Examinations for the licences of the College in medicine and midwifery are held in the week following the first Friday in each month, except August and September.

II.—Every candidate for either licence must return his name to the registrar, and lodge his certificate, bank receipt of fees, and his schedule at least *four* days before the first Friday in each month.

THE L.R.Q.C.P.I.

Every candidate is required to produce satisfactory evidence—

1. Of character, from a Fellow of the College, or from two registered practitioners.

2. Of having passed an examination in general education, held by some of the recognised examining bodies.

3. Of having been engaged four years in the study of medicine.

4. Of having attended lectures on the following subjects at recognised schools:—

Practical anatomy, two courses. Physiology, or Institutes of Medicine, one course. Chemistry, one course. Practical chemistry, one course. Materia Medica, one course. Medical Jurisprudence, one course. Practice of Medicine and Pathology, one course. Surgery, one course. Midwifery, one course.

5. Of twenty-seven months at a recognised medico-surgical hospital, in which clinical lectures and clinical instruction in medicine are given, the attendance not to be for more than nine months in any one year, and of having not less than three months studied fever in a recognised clinical hospital, containing fever wards, and recorded, from daily personal observation, at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature.

6. Of having attended practical midwifery and diseases of women for six months at a recognised lying-in hospital, or maternity; or, where such hospital attendance cannot have been obtained during any period of the student's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding public appointments; not less than twenty labour cases to be actually attended.

III.—The professional examination is divided into two parts—

First Part—Anatomy, physiology, chemistry, and materia medica.

Second Part—Practice of medicine, clinical medicine, pathology, medical jurisprudence, midwifery, hygiene, and therapeutics.

IV.—Any registered practitioner of *five* years' standing shall be admitted to examination for the licence of the College, on producing his certificate of registration, with satisfactory reference, and shall have the privilege of being exempted from the examination by printed questions.

THE LICENCE IN MIDWIFERY.

Candidates for the licence in midwifery, who are not licentiates in medicine, may be admitted to examination on the following qualifications:—

(1) The degree or license from any university or college in the United Kingdom; (2) testimonials as to character; (3) certificates of having attended (a) a course of lectures on midwifery in a school recognised by the College; (b) practical midwifery and diseases of women, for six months, at a lying-in hospital, or maternity, recognised by the College; or,

or, where such hospital attendance cannot have been obtained during any period of the candidate's course of study; of having been engaged in practical midwifery under the supervision of a registered practitioner holding a public medical appointment—the certificate, in either case, to state that not less than twenty labour cases have been actually attended.

Candidates who are already licentiates in medicine of the College, or who have passed the examination for such licence, may be admitted to examination for the licence in midwifery on lodging their fees, and signifying their wish to the registrar a week, at least, before such examination.

X.—Any registered practitioner of *five* years' standing shall be admitted to examination for the licence in midwifery, on producing his certificate of registration, with satisfactory reference; and he shall have the privilege of being exempted from the examination by printed questions.

A CERTIFICATE IN SANITARY SCIENCE is granted to Licentiates of the College upon examination.

FEES FOR LICENCE AND EXAMINATIONS.

XI.—Licence in medicine, fifteen guineas, which may be divided as follows:—

For examination at the termination of the first period of study, five guineas.

For final examination for the licence, ten guineas.

N.B.—The fee for the licence to graduates in Medicine and Arts of any University in the United Kingdom—*five* guineas.

XII.—Licence in midwifery, three guineas.

XIII.—Fee for examination of the licences in medicine and midwifery, if obtained within the interval of a month, sixteen guineas—to be lodged in one sum.

XIV.—Fee for special examination for the licence in medicine, twenty guineas.

XV.—Fee for special examination for the licence in midwifery, five guineas.

THE APOTHECARIES' COMPANY grants a registrable licence (L.A.H.), which is accepted by the Local Government Board as a medical qualification, and which, in addition, entitles the holder to keep open shop and sell drugs in Ireland. It only costs 10s., and it is taken in lieu of the licence of the College of Physicians by a few students to whom the money cost of their qualification is vitally important, or who intend to open an establishment in some of the provincial towns for the dispensing of medicines, or who want the licence as a stepping-stone to a cheap and easy Scotch diploma. Since the establishment of the Irish Pharmaceutical Society, which is empowered to grant pharmacy licences, the demand for the L.A.H. has been nominal. The cost of the L.A.H., with the necessary curriculum of study, is about £59; that of the L.R.C.S.I., combined with the L.A.H. and a licence in midwifery, is about £130.

THE ARTS EXAMINATIONS

Will be at the Hall four times in the year—viz., the third Thursday in the months of January, April, July, and October, at the hour of twelve o'clock noon.

The examination for the *Licence* is divided into two parts:—

The first part comprehends chemistry, botany, anatomy, physiology, materia medica, and pharmacy.

The second—medicine, surgery, pathology, therapeutics, midwifery, forensic medicine, and hygiene.

THE PROFESSIONAL EXAMINATIONS.

Will be held quarterly, on the first and second Monday in January, April, July, and October.

Subjects—First Part: Chemistry, botany, materia medica and pharmacy, anatomy and physiology.

Second Part—Medicine, surgery, midwifery and diseases of women and children, forensic medicine, hygiene, and clinical examination.

The first three hours of each day will be devoted to writing answers, and afterwards there will be two hours to an oral and practical examination.

Candidates at the examination on anatomy are liable to be called on to perform dissections; and at the examination on surgery, to perform one or more operations on the dead subject.

Doctors of medicine and licentiates of a college

cians who have also spent twelve months at practical pharmacy, may obtain the licence by undergoing an examination—the former in surgery and pharmacy, and the latter in medicine and pharmacy. Licentiates of the London Society of Apothecaries must undergo an examination in surgery.

QUEEN'S UNIVERSITY IN IRELAND.—This University has ceased to exist, being superseded by the Royal Irish University, which holds its first matriculation examination on the 6th of December next. All medical graduates are, *ipso facto*, entitled to become medical graduates of the Royal Irish University. The existing students in medicine of the Queen's University will also, on obtaining their degree from the Royal Irish University, be entitled to receive the title of M.D., which, under other circumstances, will be granted only to full graduates in Arts.

THE ROYAL IRISH UNIVERSITY.—This institution entered on its work as a licensing body within the past year. The degrees of the University will be granted on one year's Arts, i.e. the matriculation examination of the University (none other will suffice) and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, will be about £69. The examinations will be conducted not only in Dublin, but at certain local centres, but no dates have yet been fixed.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

THE above Society was instituted by the Pharmacy Act (Ireland) in 1875, 38 & 39 Vict., cap. 57. In that Act it is stated that whereas a great deficiency existed throughout Ireland of establishments for the sale of medicines and compounding of prescriptions, and that great inconvenience therefore arises to the public, it is expedient to amend the Act of 1791 (the Apothecaries' Act). A president (Sir Dominic Corrigan) and vice-president (Dr. Aquilla Smith), with a council of twenty-one men, were named by the Government to carry out the provisions of the Act. In 1878 Sir Dominic Corrigan resigned the presidentship. The present president is Professor Titchborne, and the vice-president, Dr. Aquilla Smith. The pharmaceutical chemist is not allowed to prescribe, but must strictly confine himself to the compounding of prescriptions. In this respect he differs from the apothecary. All persons who keep open shops for compounding prescriptions must hold the licence of the Pharmaceutical Society or the Apothecaries' Hall. Pharmaceutical chemists under the Act are entitled to hold the office of apothecary to district lunatic asylums, county gaols, and by a recent order of the Local Government Board, may also hold workhouses and dispensaries. The society, according to their Calendar, which was corrected to the 31st December, 1882, had 202 licentiates. They hold evening meetings during the winter for the reading and discussing of pharmaceutical papers and scientific papers bearing on pharmacy. This society has power under their Act to prosecute persons illegally compounding.

THE IRISH QUEEN'S COLLEGES.

THESE three important academic institutions were the special schools of the Queen's University. They have ceased to have any such relation to a central examining body, but educate students for all colleges and degrees. But they will be maintained, as hitherto, by a handsome Government grant, and the same curriculum as that heretofore adopted will be continued. The various exhibitions and scholarships will still be available. Each College has the disposal of about £450 per annum in scholarships. The curriculum is generally well adapted for preparation for the new University examinations. The Colleges are well adapted for high-class technical education, having lecture-rooms provided with every appliance necessary in the modern training of a medical student. The great want in the Colleges of Cork and Galway is a summer session. This necessitates the loss to the student

each year of three available working months, and deprives him of his practical hospital work in the summer session, both general and special. The courses of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in two-thirds of a course. The winter session commences on November 1st, and ends May 31st. The scholarship examinations are held in October. A detail of the prizes and exhibitions in arts and medicine, the names of the professors, and other information will be found in the advertisements of this issue, and full details may be had on application to—
Belfast.—John Purser, M.A., Registrar.
Cork.—Alexander Jack, M.A.
Galway.—Edward Townsend, M.A.

TECHNICAL EDUCATION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE, STEPHEN'S GREEN, DUBLIN.

THIS College supplies a complete Course of Instruction in Science, applicable to the Industrial Arts, especially those which may be classed broadly under the heads of Chemical Manufactures, Mining, and Engineering. A diploma of Associate of the College is granted at the end of the Three Years' Course. There are Four Royal Scholarships of the value of £50 each yearly, with free education, including Laboratory Instruction, tenable for two years. Two become vacant each year. They are given to students who have been a year in the College. The Chemical and Physical Laboratories and Drawing School are open daily for Practical Instruction. The Session commences on Monday, October 30th.

THE IRISH DIPLOMA IN DENTAL SURGERY.

THE examiners for the L.D.S.R.C.S.I. consist of three Fellows of the College, three registered dentists, and the President, Vice-President, or other member of the Council of the College (summoned in rotation).

The examinations embrace the anatomy, physiology, surgery, and pathology of the teeth, jaws, and surrounding parts, and mechanical dentistry, and shall be partly written and partly oral.

All candidates shall lodge at least one fortnight previous to each examination—

I.—A certificate of having attained the age of 21 years.

II.—Receipt for the fee of ten guineas.

Every successful candidate, previous to receiving the licence, shall declare that he will not advertise, or pursue any other unbecoming mode of attracting business, so long as he holds the licence in dentistry of the College.

The dental hospitals of Ireland are—that in York Street, Dublin, respecting which information will be found under the heading "Special Hospitals," and the Dublin Dental Infirmary, in Beresford Place.

NOTE.—Our advertising columns, of which an index will be found at the end of the editorial matter, will supply further information, with the names of the staff, &c., attached to the foregoing schools.

INTRODUCTORY LECTURES IN THE DUBLIN SCHOOLS AND HOSPITALS.

Royal College of Surgeons—Dr. Jacob; October 30, at 1 p.m.
University School of Physic—No information.
Catholic University School—None.
Lewish School—None.
Carmichael College—None.
Richmond Hospital—Dr. Thomson; November 2, at 10.30 a.m.
Meath Hospital—Dr. Smyly; November 6, at 10 a.m.
City of Dublin Hospital—None.
Adelaide Hospital—No information.
Mercer's Hospital—None.
Mater Misericordias Hospital—No information.
St. Vincent's Hospital—Dr. Quinlan; October 26, at 11 a.m.
Jervis Street Hospital—None.
Steevens's Hospital—None.
Retunda Hospital—None.
Coombe Hospital—No information.
St. Mark's Hospital—None.
Sir P. Dun's Hospital—None.

Scotland.

NORWITHSTANDING a great deal that might be said adverse to the multiplication of classes, and the consequently augmented cost of medical education, it cannot be gainsaid that Scotland possesses many attractions and advantages to all desirous of acquiring a sound and scientific knowledge qualifying for the discharge of the important duties devolving on the practitioner of medicine. That these will be augmented rather than curtailed by a wise legislation which recognises the cramping influences of monopolies in science, no less than in commerce, we feel perfectly persuaded. It is quite undeniable that in times gone by men have entered the profession, no less in Scotland than elsewhere, whose preliminary education, or rather the want of it, was of such a nature as to unfit them to be the interpreters of the difficult problems which fall to be solved by the physician and surgeon, or to reflect dignity on an honourable and liberal calling. The crude deductions and imperfect observations with which our medical journals are so largely filled still demonstrate the influences exerted in this direction. Within the last few years greater attention has been paid to the matter of a good preliminary education, and bad grammar, bad spelling, and bad logic can be chargeable only to some of the seniors in the profession, or such as have evaded the supervision of the examiners in a manner not creditable to themselves. That a good many of the latter are yet to be found in the ranks of the profession it were an affectation to deny.

It must be also recorded that whilst the Universities, as a rule, are doing everything to advance medical education, the Corporations still maintain that dead level of mediocrity which has characterised them in the past. They still remain as the portals by which the "chronics" of the English and Irish Schools find a ready and easy entrance into the ranks of the profession. It is the condition of these bodies which calls most imperatively for legislation, for as they now exist they offer no guarantee to the general public of the proficiency of those to whom their diplomas are granted.

A long and honourably-earned prestige attracts to the metropolis of Scotland a large number of students from all parts of the globe. It must be admitted that this is in a great measure due to the talent of the extra-mural teachers in the city, and the wholesome rivalry which exists in the matter of teaching between them and their more favoured brethren at the University. As a rule, the class of students at Edinburgh are in more affluent circumstances than in other parts of Scotland, and, it must be admitted are usually better educated. A serious drawback to the teaching of anatomy at Edinburgh—a branch so important in medical education—is the scarcity of "subjects," and the overgrown dimensions of the classes.

At Glasgow the student has now the choice of no less than four medical schools, as, in addition to the University and Anderson's College, the Royal Infirmary and the Western Medical Schools have made a fair claim to the consideration and patronage of the medical student.

Its large population, the nature of the avocations of its working classes, and its two large hospitals afford at Glasgow the most ample pabulum for medical and surgical teaching. There is no dearth of "subjects," and, without being ungracious to other teachers, it must be admitted that at one of the cheapest medical schools, viz., Anderson's College, anatomy is admirably taught. The student will have to consider for himself, and from the standpoint of his pecuniary ability as much as from any other, the features which will attract him to one or other of the four schools.

The Aberdeen School is chiefly resorted to by students native of the North of Scotland, and the excellence of the education there obtained is shown in its numerous distinguished graduates in the metropolis. If Aberdeen is weak in anything it is in the final subjects of medical education. Anatomy, physiology, and chemistry are excellently taught; but in the advanced subjects of clinical medicine and surgery, it is far behind the other Scotch Schools. The School has, however, gained materially by the appointment of Prof. Hamilton to the Chair of Pathology.

In Scotland the teaching bodies are, with one or two exceptions, so inseparably associated with qualifying corporations that it is most advisable to consider them in both relations at once.

THE UNIVERSITIES.

THE fees for the degrees in all four of the Scotch Universities are the same, viz.: £15 15s. (£5 5s. being payable at each of the three examinations), C.M. £5 5s. (in addition to the fees of M.B.), M.D. £5 5s. (in addition to the fees for M.B., and £10 for Government stamp.

UNIVERSITY OF EDINBURGH.

This is a qualifying and teaching body, and has complete Faculties of Arts, Theology and Law, equally with Medicine. Prior to commencing medical studies the student must pass a preliminary examination in English, Latin, and arithmetic, the elements of mathematics, and the elements of mechanics. An examination in at least two of the following subjects is demanded before being admitted to a professional examination, in addition to the foregoing subjects, viz.: Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy. The University confers three degrees, medical and surgical qualifications being granted—M.D., M.B., and C.M. The C.M. is not conferred unless the M.B. be taken at the same time. For the degrees of M.B. and C.M. four years of professional study must be completed after passing a preliminary education recognised by the Medical Council. A degree in Arts of any British University is held to supersede the preliminary examination. Of the four years of professional study, one must be passed in the University of Edinburgh, and another of such four years must be in some other university entitled to grant the degree of M.D. The M.D. degree is conferred on Bachelors of Medicine who have attained the age of twenty-four years, and who present a thesis to be approved by the Medical Faculty. The lectures of several extra-mural lecturers in Edinburgh, as well as those at the London medical schools, and such teachers in the provincial schools approved by the University Court, are recognised, subject to certain conditions. The total fees for graduation, including lectures, &c., are £108 18s. For regulations as to Scholarships see "Edinburgh Medical School Guide."

In *Public Health*—The University confers two degrees, a Bachelor and a Doctor of Science in Public Health.

UNIVERSITY OF ST. ANDREW'S.

This University confers the degree of M.D. (certain exemptions being made to ten practitioners yearly), M.B., and C.M. Two years of study of each candidate must be in one or more of the following Universities, viz., the University of St. Andrew's, Glasgow, Aberdeen, Edinburgh, Oxford and Cambridge; Trinity College, Dublin; Queen's College, Bel-

fast; Queen's College, Cork, and Queen's College, Galway. The degree of M.D. is conferred on any registered practitioner above the age of forty whose professional position is such as to entitle him to that degree, and who shall, on examination, satisfy the examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section to a greater number than ten in any one year. The examinations are held yearly towards the end of April.

UNIVERSITY OF GLASGOW.

This is both a teaching and examining body. It confers three degrees, viz.: Bachelor of Medicine, Master of Surgery, and Doctor of Medicine. Before graduating the student must have been engaged in medical study for four years, one of which must have been spent at the University of Glasgow, and the others at some university or school recognised by the Glasgow University. A *medicus annus* is constituted by two courses of 100 lectures each, or by one course of 100 lectures and two of 50 each. Two preliminary examinations must be passed, one before commencing study, and the other before appearing at the first professional examination. A degree in Arts (not honorary) exempts the student from these examinations.

Public Health.—A special examination is held in subjects relating to Public Health, and a certificate granted by the University.

Bursaries tenable by Medical Students.—The Brisbane Bursary of £50 yearly, held for four years by a student of medicine who is a Master of Arts. The Walton Bursary, of £36 yearly, held by a medical student (a native of England being preferred) for four years. The Logan Bursary, of £16 yearly, tenable by a medical student for four years. Two Rainy Bursaries, value £20 per annum each, open to medical students who have just completed the second year of professional study, and tenable for two years. The Armagh Bursaries, three in number, amounting each to £25 yearly for three years, open to students of divinity, law, and medicine who have taken the degree of M.A. The Macfarlane Bursary, value £40 per annum, and tenable for three years, open to students who have attended the first session of their professional study in the University of Glasgow, and who have passed in all the seven subjects of the preliminary examination for M.B. The Marshall Bursary, value £17 per annum, and tenable for four years, open to students entering the Medical Faculty, and awarded by competition on the subjects of the Preliminary Examination. The Lorimer Bursary, value £50 per annum, tenable by a medical student for three years.

Both at the University of Glasgow, and the University of Edinburgh, numerous "extra-classes" are taught, which are virtually as compulsory as the regular classes of the curriculum. The expense of education is thus much greater than at first sight appears, and the student, to whom money is an object, would do well to take this matter into consideration.

UNIVERSITY OF ABERDEEN.

This University is entitled to confer degrees in all the Faculties, and is a teaching body as well. The curriculum of study is nearly the same as in the University of Edinburgh. One year must be passed at Aberdeen. Another of such four years must be either in this University or in some other University entitled to give the degree of M.D. With regard to fees each candidate for the degree of M.B. must pay a fee of £5 5s. in respect of each of the professional examinations. If he desires to be admitted to the degree of M.B. only he will not be required to pay any further fee in addition to the £15 15s.; but on admission to the degree of C.M. he must pay a further fee of £5 5s., in addition to the fees for the M.B. degree. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in April and July, directly after the close of the winter and summer sessions.

Substantial encouragement to medical students is offered at this University in the form of bursaries, and quite recently 2,000*l.* have been bequeathed to it for endowment of four new medical bursaries to be termed the "Watt's Bursaries" and the "Marr Bursaries," of an annual value of from 20*l.*, to 25*l.*

The Degree of M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and is of the age of twenty-four years, and has been engaged subsequently to his having

received the degree of M.B. for two years in attendance in an hospital, or in military or naval medical service, or in medical or surgical practice. Provided always that the degree of Doctor of Medicine shall not be conferred on any person unless he be a graduate in Arts, or unless he shall before or at the time of his obtaining the degree of Bachelor of Medicine, or thereafter, have passed a satisfactory examination in Greek and in Logic or Moral Philosophy.

THE COLLEGES.

Royal College of Physicians, Edinburgh.—This, like the sister College of London, is exclusively a qualifying body. In conjunction with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, this College grants a double qualification, and registerable as such. Each applicant for the professional examination must previously have passed one of the preliminary examination recognised by the General Medical Council. Exemption is made in the case of masters or bachelors of Arts, of any British University and certain recognised foreign Universities. Candidates who may have already passed the first professional examination of any body approved of by the College will, on completion of their studies, be admitted to the second part of the examination.

The Fellowship, is conferred only by election, and the candidate must have been a member of the College for at least one year previously, and have attained the age of twenty-five years.

The Membership is conferred only on licentiates of the College or graduates of a British or Irish University after an examination in Medicine and Therapeutics, and in another branch of Medical Science to be selected by the Candidate. Under certain conditions as to age and professional standing, Candidates may, however, be admitted without examination.

The Licence.—The regulations are nearly the same as those for the joint examination for the Scotch double qualification.

The professional examination will be divided into two parts, according to the following arrangement of subjects:—1. Anatomy, physiology, chemistry; 2. Materia medica and pharmacy, pathology, and pathological anatomy, practice of medicine, surgery, midwifery, medical jurisprudence, clinical medicine. No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be partly oral, partly in writing. Qualified practitioners may obtain the licence by passing an oral examination in the subjects of the second examination.

Qualification in Public Health.—The College now confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10*s.*

Fees.—The fee payable by a licentiate is £15 15*s.* In the case of unsuccessful candidates the fee is returned, minus the expenses of examination. The fee to be paid by a member is £31 10*s.* When a licentiate is raised to the rank of member, he pays £21, or £15 15*s.*, according to the date of his licence. When a member is raised to the rank of a fellow, the fee is £31 10*s.*, exclusive of stamp-duty, which amounts to £25. All candidates for the fellowship or the membership must lodge their fees and the amount of stamp-duty payable at the time to Government with the treasurer, previously to presenting their petitions.

Royal College of Surgeons of Edinburgh.—Candidates for the diploma of this College must have followed a course of study in some University, or in an established school of medicine, or in a recognised provincial school.

Preliminary Examination.—All candidates for the diploma of the College must have passed the complete preliminary examination prescribed by the General Medical Council, and have their names inscribed on the register of medical students at the commencement of their medical studies. The preliminary examination of certain recognised bodies is accepted by the College.

Professional Study.—Candidates must have been engaged, during four years after the preliminary examination in general education, in professional study, which shall include not less than four winter sessions, or three winter and two summers' attendance at a recognised medical school.

Professional Examination.—The professional examination is divided into two—the one oral, the other written. The first examination embraces anatomy, physiology, and chemistry, and for this candidates may appear at the end of their second winter. The second examination embraces

surgery and surgical anatomy; also medicine, midwifery, *materia medica*, and medical jurisprudence; and does not take place prior to the termination of the winter session of the last year of study.

The Fellowship is conferred only on candidates who have obtained a diploma from this College or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are twenty-five years of age. The election is by ballot, and three-fourths of the votes are required to be in the candidate's favour; he has also to subscribe certain bye-laws of the College. Fellows are forbidden to keep open shops, to be connected with secret remedies, or indelicate advertisements or publications.

The Licence.—The regulations are almost the same as those for the joint examinations conducted by the Colleges of Physicians and Surgeons.

Dental Diploma.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a university or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. This diploma may, in certain cases, be given after examination, but *sine curriculo*.

THE SCOTCH DOUBLE QUALIFICATION.

The Royal College of Physicians of Edinburgh, by a certain arrangement, grants conjointly with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons, Glasgow, after one series of examinations, a double qualification, two diplomas being given and registered under the Medical Act as medical and surgical qualifications, thus: Lic. Roy. Coll. of Phys. Edin. and Lic. Roy. Coll. of Surg. Edin., or Lic. Roy. Coll. of Phys. Edin. and Lic. Fac. Phys. and Surg. Glas., according as the case may be.

By the understanding subsisting between these bodies, the College of Physicians takes exclusive charge of the examination in medicine; and the College of Surgeons or the Glasgow Faculty, of that in Surgery; whilst departments common to both medicine and surgery are examined by a board in which each body is represented. Such arrangements as these were contemplated by the Medical Act, and authorised by Section XIX., and those under consideration were sanctioned by the Medical Council, 7th August, 1859.

Candidates having fulfilled the full curriculum are subjected to two professional examinations. Hereafter the preliminary examination must be passed before commencing professional study, and must be otherwise conformable to the regulations of the Medical Council.

Total fee for double qualification is £21.

Faculty of Physicians and Surgeons, Glasgow.—The Faculty grants a Licence in Surgery and a Fellowship. In conjunction with the Edinburgh College of Physicians it grants a double qualification. The regulations and fees are the same as the Edinburgh colleges.

School of Medicine, Edinburgh.

This, constituted by the whole body of lecturers licensed by the Colleges, meets for the purposes of teaching in separate buildings, of which Surgeons' Hall and Minto House are the chief. At Surgeons' Hall, the parent meeting-place of the School, some of the older teachers still lecture; but owing to the want of better accommodation and the lack of that enthusiasm which characterises its younger rivals, the classes, with one or two exceptions, are not as large as they formerly were.

Surgeons' Hall.—The chemical laboratories are under the care of Dr. Macadam. Medical jurisprudence laboratories—Dr. Littlejohn. *Materia medica* laboratories—Dr. Moinet. Dissecting-rooms—Dr. Cathcart. Pathological laboratories—Dr. Buist. Physiological laboratories—Dr. James.

The lectures of this School qualify for the University of Edinburgh and the other Universities, and the Royal Colleges of Physicians and Surgeons, Edinburgh, London, and Dublin, and the other medical and surgical boards.

Total fees for double qualification, £95.

For further details, see "Edinburgh School Guide."

Minto House.—This School is a part of the Edinburgh Extra Academic School of Medicine, and in it the following means are afforded for practical instruction:—

The dissecting-rooms are open daily from 9 a.m. till 4 p.m., under the superintendence of Mr. Symington and assistants.

The chemical laboratories are open daily from 9 a.m. till 5 p.m. for instruction in practical and analytical chemistry,

under the superintendence of Mr. J. Falconer King, Mr. Hunter and assistants.

The medical jurisprudence and public health laboratories are open daily, under the superintendence of Dr. Aubrey Husband.

The *materia medica* museum and laboratory are open daily, under the superintendence of Dr. Craig.

Clinical instruction in diseases of women and in the minor gynecological operations is conducted in the Western Dispensary and Obstetrical Museum, under the superintendence of Dr. Halliday Croom.

The pathological laboratory is open daily from 10 a.m. till 4 p.m., under the superintendence of Dr. Waller.

The physiological laboratory is open daily from 10 a.m. till 4 p.m., under the superintendence of Mr. James Hunter.

Clinical instruction in diseases of children, at the Royal Hospital for Sick Children, on Tuesdays, Thursdays, and Saturdays, at 11.30 a.m.

Clinical instruction in diseases of the ear at the Ear Dispensary, on Mondays and Thursdays, at Twelve Noon.

Clinical instruction in diseases of the skin, Royal Dispensary, on Wednesdays and Saturdays, at 1 p.m.

Clinical instruction in diseases of the throat, at the Western Dispensary, on Wednesdays and Saturdays, at 5 p.m.

The dissecting-rooms and chemical laboratories open on October 4th.

Edinburgh Royal Infirmary.—Clinical instruction is afforded at this institution under the supervision of Professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, physical diagnosis, and diseases of the eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, &c. The perpetual fee, in one payment, is £12; the annual fee, £8 6s.; half-yearly, £4 4s.; quarterly, £2 2s. Separate payments for two years entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

Dispensaries in Edinburgh.—At these institutions students may take out the necessary practice required by the examining bodies.

Dental School and Hospital, Edinburgh.—The hospital practice and lectures qualify for the dental diplomas of the Royal College of Surgeons, England, Royal College of Surgeons, Edinburgh, and Royal College of Surgeons, Ireland. For further information, apply to James Robertson, 4 Lindsay Place, Edinburgh, or to Mr. W. B. Macleod, Dean of the School.

Glasgow, Anderson's College.—This is exclusively a teaching body. In addition to its offering excellent opportunities for acquiring a good medical education, instruction is given in the other branches of a liberal education, advantage of which might profitably be taken by medical students generally. The expenses of this institution are exceedingly moderate, the fees for all lectures and hospital practice required of all candidates for the double qualification of the Scotch Colleges being £48. Extensive opportunities for dissection are offered, under the guidance of the Professor of Anatomy. Several scholarships, &c., are offered by the College.

In connection with the college, there are five hospitals and dispensaries for special diseases, to all of which students are admitted.

The Summer Session at this College begins on the first Tuesday of May, and closes about the middle of July. A Lectureship on Aural Surgery has been established. Lectures on Dental Anatomy and Surgery are also given four times weekly. The fee for two years' hospital practice required by the curriculum for the Dental Licence is £10 10s. Fees for Dental Lectures are £2 2s. each course.

Further particulars may be obtained on applying to Dr. A. M. Buchanan, Dean of the Medical Faculty.

Glasgow Royal Infirmary.—Number of beds, 532. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of venereal diseases and the diseases of women; whilst diseases of the eye, ear, throat, and teeth are specially treated at the dispensary. Courses of clinical medicine and surgery are given by the physicians and surgeons, and post-mortem examinations are conducted in the pathological theatre by the pathologists, who also give practical instruction in pathological anatomy and histology.

Appointments.—There are five physicians' and five surgeons' assistants. The appointments can be held for six or twelve months, and are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are elected from the students.

Fees for hospital practice and clinical lectures, first year, £10 10s.; second year, £10 10s., afterwards free. For six months, £6 6s.; three months, £4 4s.; Students who have paid 20 guineas at another hospital for its perpetual ticket are admitted six months for £2 2s., or one year for £3 3s. Vaccination certificate, recognised by Privy Council, £1 1s.

Glasgow Royal Infirmary School of Medicine.—The winter session will commence on October 29th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures are also given on practical physiology, operative surgery, aural surgery, dental surgery, and diseases of the eye. During the summer, lectures on insanity are given by Dr. A. Robertson, and the City parochial asylum under his charge is free to students of this school. Students have unusual facilities for the study of anatomy, the supply of subjects being practically unlimited.

Class Fees.—For each course, first session, £2 2s.; second session and perpetual, £1 1s. Students who have attended a first course elsewhere can enter on the second course on payment of £1 1s. Anatomy, first winter session, £4 4s.; summer session, £1 11s. 6d.; second winter session, £1 4s.; afterwards the fee for lectures and practical anatomy is £1 1s. per session. Lectures on diseases of the ear, £1 1s.; with clinique to those who are not students at the Hospital, £2 2s. Clinique on dental surgery, free to students of the Hospital; to others, £5 one year, perpetual, £10. Lectures on diseases of the eye, £1 1s. Lectures on dental surgery, £2 2s.

Glasgow Western Medical School, University Avenue, Hill-head.—The Winter Session of this School will open on November 1st. The school is situated close to the University and the Western Infirmary, where students can obtain their clinical lectures and hospital practice. The class-rooms have been newly arranged and enlarged. The dissecting-rooms are open for work from the beginning of October till the end of July.

The lectures qualify for the University of Glasgow, the Faculty of Physicians and Surgeons, Glasgow, and the other corporations.

Class Fees.—For each course of lectures, First Session, £2 2s.; Second Session, £1 1s. Students who have attended a first course elsewhere pay £1 1s. Anatomy, including practical anatomy, £4 4s. Summer Session £1 11s. 6d.

THE SERVICES.

I.—THE ARMY MEDICAL DEPARTMENT.

THE Royal Warrant, dated 25th June, 1881, placed this branch of the public service pecuniarily in a better position than it had previously enjoyed. The rates of pay under that Warrant are as follows, viz.: Surgeon-General, £2 15s. per day, or if at headquarters, £1,300 yearly; Deputy Surgeon-General, £2, at headquarters, £900 yearly; Brigade-Surgeon, £1 10s. to £1 12s., at headquarters, £750 yearly; Surgeon-Major, £1 to £1 7s. 6d., according to length of service, at headquarters, £650; Surgeon, £200; after five years' service, £250 a year; after ten years' service, 15s. daily, equal to, say, £273 per annum. While on probation the surgeon receives 8s. per day. Relative rank is as follows:—As Major-General, Director-General, and Surgeon-General; as Colonel, Deputy Surgeon-General; as Lieutenant-Colonel, Brigade-Surgeon, and Surgeon-Major after twenty years' service; as Major, Surgeon-Major of less than 20 years' service; as Captain, Surgeon; as Lieutenant, Surgeon on probation. The pay of medical officers is issued monthly in arrears.

A candidate must possess two diplomas or licences, one in Surgery and one in Medicine; he must be registered. His age on appointment not to exceed 28 years. Not less than half the number of appointments to be through public competition. The Secretary of State for War may fill up the remaining number by candidates proposed by

the governing bodies of schools of medicine in the United Kingdom or Colonies. Application to be made to Director-General. On passing satisfactorily through the Army Medical School at Netley he obtains his commission, the order of precedence being in that of merit at the final examination. Medical officers, soon after being gazetted to the service are sent to Aldershot and other large stations for instruction in ambulance and army hospital corps duties.

Promotion to the rank of Surgeon-Major to be after twelve years' service, three of which abroad; but for distinguished service promotion to be irrespective of seniority. To the rank of Brigade Surgeon promotion to be by selection for ability and merit, provided the Surgeon-Major has had eight years foreign service in all. From Brigade Surgeon to Deputy Surgeon-General, and from the latter rank to that of Surgeon-General. Promotion to be by selection. If appointed as Honorary Physician or Honorary Surgeon to Her Majesty, a medical officer, if under the rank of Deputy Surgeon-General, shall, if duly qualified, be promoted to that rank.

On completion of ten years' service a medical officer may retire on a gratuity or pension, if specially recommended by the Commander-in-Chief and Secretary of State for War. If retiring voluntarily before the age of 55, he is liable to be called upon to serve in the case of national emergency. A Brigade Surgeon, Surgeon-Major, or Surgeon, shall be placed on the retired list at 55 years of age. A Deputy Surgeon-General or Surgeon-General at 60. A step of honorary rank is attainable on retiring after twenty years' full pay service. Exchanges are permitted. Good service pensions are granted in larger numbers than heretofore. Sick leave may be allowed for six months, and in special cases for a second period of the same extent—that is, a year in all. Temporary half-pay is granted under particular circumstances to medical officers incapacitated for duty by illness.

Non-effective pay, or gratuity in lieu, thereof is granted. To a medical officer of 10 to 18 years' service a sum of £1,250 to £2,500; Surgeon-Major from 20 to 30 years' service, £1 to £1 5s. 0d.; Brigade Surgeon, £1 7s. 6d. to £1 10s.; Deputy Surgeon-General, £1 15s.; Surgeon-General, £2.

Retired medical officers, and medical officers of the Militia, are eligible for employment up to the age of 63, receiving during the time of such employment a consolidated salary in place of retired pay.

II.—THE INDIAN MEDICAL SERVICE.

By recent regulations the conditions of service, pensions, and honorary awards in the Indian Medical Department have been in a great measure assimilated with those of the medical branch of the general army. It is right, however, that we allude to the fact that rumours are in circulation regarding further changes in the constitution of the Indian Department.

The examination usually takes place in February and August, when candidates are examined in the following compulsory subjects: a. Anatomy and Physiology. b. Surgery. c. Medicine, including Therapeutics, the Diseases of Women and Children. d. Chemistry and Pharmacy, and a Practical Knowledge of Drugs. The examination in Medicine and Surgery is in part practical, and includes operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The eligibility of each candidate will be determined by the examinations in these compulsory subjects only.

Optional Subjects.—Candidates who desire it will be examined in French, German, and Hindustani, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to *Materia Medica*; and the number of marks gained will be added to the marks in the obligatory part of the examination, and position on the list of successful competitors will thus be improved in proportion.

Probation at Netley Hospital.—The competitor who

obtains a place in the ordinary service is obliged to undergo probation of four months at Netley Hospital, where he attends the following lectures: Pathology, by Dr. Aitken; Military Surgery, by Dr. Langmore; and Clinical and Military Medicine, by Dr. Maclean; Military Hygiene, Dr. de Chaumont. The lectures on Military Surgery include gun-shot and other wounds; duties of army surgeons in the field, during sieges, on transport, &c., and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease. The lectures on Hygiene relate to the examinations of water, air, food, and clothing, &c., of the soldier, his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the army surgeon is especially called on to investigate. The candidates also attend the wards of the hospitals under the Professor of Medicine and Surgery, to make themselves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make post-mortem examinations, to operate on the dead body, and to pass through laboratory practice on the modes of recognising the qualities and adulterations of food, and on microscopic examination of morbid tissues, &c. During his preliminary training here the student is understood to be in Her Majesty's Service; he wears uniform, is under military discipline, and receives pay as already stated. A sum of money, equal to the half-yearly interest on £1,200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks, the fortunate young man who wins the "Blue Ribbon of Netley" being tolerably certain to be well provided for.

III.—NAVAL MEDICAL SERVICE.

The arrangements, time, and places for examination, the declaration to be made, and documents produced, the subjects and method of examination, and the subsequent probation at Netley, are to all intents exactly the same as those quoted above for the Army and Indian Medical Services.

Fleet surgeons have the option of retiring after twenty years' full pay service in all ranks at 15s. per day, and after twenty-five years, 21s.

Medical officers share in the proceeds of all prizes.

The following rates of pay and retiring allowances are granted under Admiralty Regulations dated 7th October, 1875, namely:—

Full pay Surgeons from 11s. to 17s. per day, according to length of service. Staff Surgeons, £1 3s. to £1 10s.; Deputy Inspector-General, £1 11s. to £1 18s.; Inspector-General, £2 5s. to £2 10s. 6d.

Half pay Surgeons, 6s. to 11s.; Staff Surgeons 11s. to 14s.; Fleet Surgeons, 16s. to 18s. 6d.; Deputy Inspector-General, £1 1s. to £1 7s. 6d.; Inspector-General £1 11s. to £1 18s.

IV.—ENGLISH POOR-LAW MEDICAL SERVICE.

The English Poor-law service differs in many respects from the Irish. Each parish in England and Wales has its guardians of the poor, and these parishes are grouped together to form unions. The unions are divided into districts for medical relief. A Union medical officer therefore has the care of a district, and sometimes of a workhouse as well; sometimes only a workhouse. He is elected by the guardians of the union, and the appointment confirmed by the Local Government Board. He must have both a surgical and medical qualification, and be registered, and is required to name a duly-registered practitioner to whom application can be made in case of his absence from home; he can name his assistant or partner as his substitute. As a general rule, the guardians may not assign to any medical officer a district which exceeds in extent an area of 1,000 acres, or which contains a population exceeding

15,000 persons. This does not apply to Wales, but no such district may be assigned to a medical officer residing more than seven miles from any part of a parish included in such district. A medical officer is entitled to a fee of not less than 10s., or more than 20s. for attending a woman in or immediately after childbirth, and to a fee of £2 where great difficulty has occurred in delivery, or long subsequent attendance has been necessary. Many of the salaries of Poor law appointments are very low—often so out of proportion to the work done that the medical officer must give his services for nothing, or next to nothing, as he has to provide all medicines, instruments, &c., except trusses, cod liver oil, and quinine, for which he sends a statement to the guardians, who pay him the cost price; the paupers have to put up with those medicines which cost the least. In London and large towns some boards of guardians provide dispensaries, where the paupers are supplied with medicine, which relieves the medical officer from much labour and expense. It ought to be compulsory on all boards of guardians to provide dispensaries, and where this cannot be done, as in country districts, to provide all drugs, &c.

Clubs.—In England and Wales (more especially in the manufacturing districts) the medical practitioner derives much of his income from clubs, which pay him from 3s. to 4s. per head yearly, for which he visits and supplies medicines, &c.; the average payment for each visit amounts to the large sum of about 6d. Parish appointments are often sought for by young men as an introduction to practice, or by older men to prevent opponents setting up in the district.

V.—THE IRISH POOR-LAW MEDICAL SERVICE.

The newly-qualified medical practitioner who may elect to try his luck in the Irish provinces sets his hopes in the great majority of instances upon obtaining one or more Poor-law medical appointments in some district where there is hope of private practice. There are 163 workhouse and about 808 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The salary in this service averages about £103 15s.; and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep a horse, and in some a boat as well, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments. The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act passed in '73 and amended in '78.

The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate every one who wishes to come. For each patient his fee of 2s. is paid, along with his salary, by the guardians, and the sum total of these fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10. Despite the miserable salary, and the very many discomforts of dispensary life, these appointments are generally eagerly sought for—firstly, because they afford the new comer a certain, though hardly-earned salary, to supplement his private earnings; and, secondly, because, if not secured by the new comer, they would of necessity bring a competitor for office into the field, and inasmuch as private income is of far greater import than public earnings, country medical practitioners are obliged to undertake the public duty in order to save themselves the monopoly of their private emoluments.

Appointments.—The qualifications required by the Poor-law Commissioners are a Licence in surgery or a Diploma in medicine, and a Diploma in midwifery; the candidate must also be twenty-three years of age.

The appointment lies with Dispensary Committee, who

elect by vote. As politics and religious feeling run high in Ireland, these elements enter largely into the election of Poor-law medical officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required, and whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential; and, accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away.

Duties.—The duty of the dispensary doctor is twofold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have perhaps to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a member of the committee or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the same. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest degree dependent on the goodwill of the members of his committee. If the medical man be a favourite with his masters, they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour of the paper on which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred committee men, who know nothing of the treatment fit for an educated gentleman, or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned, in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay—aye, even to the committeeman's own brother or daughter.

Workhouse Hospitals.—The number of unions in Ireland is 163, to each of which is attached a medical officer, who is appointed and controlled by the Board of Guardians in the same manner as the dispensary surgeon is by his committee. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospital, and no night visits out of doors or any long journeys across the country are involved.

Superannuation.—A Poor-law medical officer may now receive a pension not exceeding two-thirds of his salary on being incapacitated from illness or old age. This grant is strictly at the discretion of the guardians; nevertheless, it has been given in most cases in which physical incapacity has been clearly proved. There are now about 60 ex-medical officers receiving superannuation allowance, whose average term of service before pension was 20 years, and whose allowance averages about £60. Their average age at retirement was 63.

Complete information as to fees, emoluments, duties, and appointments of Irish Poor-law medical officers will be found in the "Irish Medical Directory" for 1882.

VI.—SCOTCH POOR-LAW MEDICAL SERVICE.

Practically these appointments, once made, are held *ad vitam aut culpam*, while in terms of the strict letter of the law they are but yearly appointments. Arbitrary dismissal is, however, guarded against by the powers of the Board of Supervision. It is expected that soon parochial medical appointments will be legally placed on the footing of permanent ones, and that a re-

tiring allowance will be provided for the medical officers, as is the case in Ireland. The emoluments received from the parochial boards vary according to the number of paupers, size of the parish, and often the local exigencies requiring the residence of a medical man. The salaries may be said to range, on an average, from £30 to £100 per annum. In remote and thinly-peopled districts the landed gentry and large farmers assess themselves in sums varying from £5 to £20 to make up an adequate income to the doctor, which, however must be held in lieu of fees for medical attendance. Should such attendance, however, be much in excess of any such sum, the doctor is usually safe in trusting to the honour and generosity of the Highland gentleman, for this arrangement is more peculiar to the Highlands of Scotland. The young doctor has more speedy and easy access to "good society" in the country than in large cities; and perhaps better society than the latter; and should he be worthy of it he is certain to command respect and courteous treatment, and, with limited ambition and sporting tastes, to lead a useful and happy life.

NOTICE.—The Editor desires to thank those gentlemen attached to the various Medical Schools for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO READERS.—As this number is devoted exclusively to information necessary for students intending to join one or other of the various medical schools; and for those who, having passed their curriculum, are about to enter into the ranks of the profession, the ordinary matter which fills our columns is necessarily deferred till next week. Should any of our readers desire to present this number to a patient or friend who contemplates sending his son to a medical college, our Publisher will be happy to supply him with a duplicate free of cost.

INDEX TO THE ADVERTISEMENTS OF MEDICAL COLLEGES, HOSPITALS, SCHOOLS, &c., IN THE UNITED KINGDOM.
On reference to which the Prospectus, Names of Teachers, Hospital Staffs, &c., will generally be found.

from germs present in the soil and which float over the air of marshes; and that by treating with water the soil of a fever-haunted marsh of the Campagna the germs of this organism could be washed out; and that the water containing the organisms thus obtained, introduced into the circulation of a dog, produced ague more or less rapidly and more or less violent according to the numbers in which the organisms were present in the water.

This theory no doubt agrees with certain well-known facts.

In a tropical climate, if soil which has been long undisturbed, or the soil of marshy ground, be turned up, intermittent fever is almost certain to ensue.

In illustration of this, I recollect that at Hong Kong the troops were unhealthy, and a beautiful position on a peninsula exposed to the most favourable sea breezes was selected for a new encampment. The troops were encamped upon this spot for some time to test its healthiness, which was found to be all that could be desired. It was then resolved to build barracks—as soon as the foundations were dug, fever broke out.

As an instance of this nearer home I may mention that last winter at Cannes, in the south of France, some extensive works adjacent to the town were begun which required a large quantity of earth to be moved. The weather was exceptionally warm—an outbreak of fever occurred among the workmen, of whom fifteen died: this fever was attributed to the turning up of the soil.

If a strong solution of quinine be let fall in the water containing these organisms, they at once die: the efficacy of quinine as a preventive of this form of fever would therefore not be inconsistent with this theory.

Dr. Sternberg of the United States Army, who made experiments on the soil, water, and air of New Orleans, whilst he is unable to confirm the views of Professors Klebs and Crudelli, admits that there are many circumstances in favour of the hypothesis that the etiology of these fevers is connected, directly or indirectly, with the presence of these organisms or their germs in the air and water of malarial localities.

Sir Joseph Fayrer, whose large experience in India has given him exceptional knowledge of malarial fevers, in speaking of these researches of Klebs and Crudelli, says that the importance of such a discovery, if it were confirmed, could not be over-rated; because, if we take the world over, it is probable that some form of malaria is the most fruitful cause of disease; and that this theory offers an explanation which appears to correspond with what we know of the mode of operation of malaria:—First, that it occurs at certain heights, and that it is not necessarily connected with the presence of marshes, ponds, or rivers, nor with admixture of fresh or salt water, nor with the putrefaction of an organic substance. Second, that the production of malaria ceases when the air can no longer act on the soil; for the most pestilential marshes cease to be so when they are covered with water, or when the air is excluded by any interposing substance. Third, that a very moderate degree of humidity will produce malaria. Some malarial soils, innocuous during hot and dry weather, become dangerous after a shower, and so in the case of the upturning of new ground or the cutting down of jungle.

But he adds the following words of caution: “In our natural anxiety to find a particular origin for the poison or germ, we must not overlook the possibility that the results attributed to the so-called malaria may be due to disturbance of the system caused by gaseous emanations or by some other agencies, in a body predisposed to be so deranged by peculiarity of constitution, climatic, or other influence, of the nature of which we are ignorant, though it is conceivable by analogy.”

In the case of certain of the diseases mentioned, some very curious and valuable results have been obtained—results analogous to that of vaccination in the case of small-pox.

If a point of a needle be dipped in the blood of a fowl

suffering from chicken cholera, and then placed in a vessel containing pure chicken soup, from which care has been taken to exclude all contamination by air-borne germs, and a suitable temperature be maintained, the bacterium or microbe (as M. Pasteur terms it), and cognate organisms which are found in the blood of the diseased fowl, multiply and render the liquid turbid by their presence. If a drop of the contents of this vessel be transferred to another portion of similar chicken soup, it, too, speedily becomes permeated with the organism. The process may be repeated a hundred times; and the result inoculated upon fowls, or given them in their food, will produce the same fatal effects. But if the infected chicken soup be allowed to remain for a few weeks or months, the malignant powers diminish: it becomes, as Pasteur terms it, “attenuated.” A given quantity of infected chicken broth, even at the hundredth rapid cultivation, inoculated upon twenty chickens, would probably prove fatal to eighteen of them. If the same infusion were allowed to remain exposed to the air for a month it would be so far attenuated that it would only prove fatal, say, to ten. Exposure for another month would render it still less virulent, so that it would only prove fatal to two or three; while after exposure for six or eight months it would not prove fatal in a single instance. In its most attenuated form the infusion gives rise only to trifling local symptoms, not at first recognisable as bearing any affinity to the deadly fowl cholera, and consisting of a small local slough. But the valuable fact discovered by M. Pasteur is that the attenuated infusion works upon the system a change protective against subsequent attacks of fowl cholera, exactly similar to that which has been remarked to be enjoyed by fowl that had recovered from the virulent form of the disease. Similar results are obtained in the case of anthrax or splenic fever in cattle.

When we consider the marvellous facility of reproduction of these various germs, shown by these discoveries, we wonder how any higher form of life can exist subject to the possibility of invasion by such countless hosts of occult enemies.

But as we pursue the subject further, we find that the science of the prevention of disease, that is to say the science of hygiene, advances quite as rapidly as our knowledge of the causes of disease.

The practice of mitigating the severity of attacks of disease by producing voluntarily a milder form of the disease is not new. Inoculation for small-pox has been practised in various ways from the most ancient times; because it was known that the occurrence of the disease caused some change in the blood or in the system of the person suffering from it which prevented the development of the disease a second time, or mitigated the attack.

Jenner showed us that the milder disease of cow-pox caused a change in the system which produced a similar result.

With regard to more recent investigations, the most cautious observers are prepared to admit that in some diseases, such as anthrax, fowl cholera, and in some other diseases, it has been proved that there are certain organisms in the blood, or in the tissues, or in the morbid fluids in animals suffering from disease; that blood or fluids containing the organisms or their spores transmit the disease when inoculated; that when these organisms are absent or artificially separated, inoculation gives no such result; that the organisms can be cultivated outside the animal body, and after ten or fifteen generations the fluid which contains the cultivated organisms can reproduce the original disease when inoculated; and that the method of cultivation can modify or increase at will the virulence of the communicated disease.

There are some other diseases of the zymotic class besides those mentioned above, in which there is a probability that organisms may cause the disease; but experiments have not hitherto absolutely settled the question; and for the present our attitude must be one of reserve, much as we should wish it should prove all true.

But even if the views of those who are prepared to accept the germ theory of disease to its fullest extent were shown to be true, it seems also to be certain that if the invasion of these occult enemies present in the air is undertaken in insufficient force, or upon an animal in sufficiently robust health, they are refused a foothold and expelled; or if they have secured a lodgment in the tissues, they may be, so to speak, laid hold of and absorbed or digested by them. In corroboration of this view Professor Koch and others state that the minor organisms of tubercular disease do not occur in the tissues of healthy bodies, and that when introduced into a living body their propagation and increase is greatly favoured by a low state of the general health.

The record of facts enunciated by the various scientific inquirers into the germ theory of disease affords an interesting contribution to the solution of etiological questions; but these inquirers have not yet given the sanitarian grounds of practical action, and for the present, at least, sanitary procedure is quite independent of them.

The remaining portion of the address was devoted to a consideration of the influences affecting the death-rate under various conditions, and was amply illustrated with statistical tables.

SULPHUROUS ACID VAPOUR IN THE TREATMENT OF CONSUMPTION.

By D. H. CULLIMORE, M.K.Q.C.P., F.R.C.S.I.,

Physician N.W. London Hospital; formerly Medical Staff Indian Army.

HAVING been long convinced, as shown by my writings published in 1880, of the contagious character of pulmonary consumption, a fact which the recent discovery of the tubercular bacillus most clearly demonstrates to the satisfaction of the most sceptical, I have lately been occupied in testing the relative merits of the various antiseptic agents as inhalations in this disease, mainly with a view of finding out one that might prove an antidote to its specific poison. I believe, for reasons which I will bring forward as I proceed, that such an antidote will be found in sulphurous acid, or the vapour of sulphur administered in combination with other drugs, so as to minimise or entirely counteract its irritative properties, and disagreeable odour. However, as when the most universally accepted antidotes are limited in their action, and their success or failure determined by the intensity of the poison or its duration in the system, so will similar conditions influence the remedial action of any antidote to the ravages of the tubercular bacillus. Thus, it must not be imagined from the discovery of the bacillus of Koch that the direct application by inhalation of the most suitable remedy will at once, and in every case, be followed by a cure. Those who expect this will assuredly be disappointed, no such beneficial revolution can be accomplished, particularly in a chronic disease, where every stage is bound up with inflammation, and whose whole pathology may be briefly and correctly summed up as a combination of the pathological processes of the three forms of pneumonia, viz., the croupous, the catarrhal, and interstitial. No! This specific tubercular virus is intimately connected with the inflammatory processes, which acting sometimes as an existing, and sometimes as a predisposing cause, always furnishes the most suitable nidus for its hatching and propagation. Hence, if we would manage consumptives with advantage, we must remember, that while the bacillicide with pure air is our sheet anchor, the treatment of inflammation by counter-irritants and occasional anti-phlogistics must not be neglected. Its climatic aspect is also important. The latter is specially necessary to bear in mind in reference to winter mountain climates, for that which is best for the specific affection may be unendurable to its attendant inflammation. Moreover, I do not contend that sulphur

is alone capable of rendering inert the bacillus of tuberculosis, for great heat and extreme cold if unattended with moisture, have probably the same effect. Some physicians of eminence are also of opinion that mountain air acts in the same manner owing to its anti-putrefactive properties, which anti-putrefactive property mountain air *per se* does not possess more than the air of the plains, for I have myself seen decomposing meat at a height of 4,500 feet, and have even had occasion to condemn it. Overcrowding, diet, bad drainage and moisture will prove as injurious on the hills as the lowlands. The pure air which M. Pasteur found so deleterious to the life of his microbisms is probably equally beneficial at whatever elevation it is found. Withal, so far as drugs are concerned, the analogy, the teachings of history, even my own experience of the sulphur show that it is not only *primus inter pares*, but without a rival or a peer. There are some anti-contagionists, whose pickets being driven in by the discovery of Koch, yet stoutly maintain that there is nothing specific in the bacillus of tuberculosis, that it is not essential to the development or spread of consumption, but merely an epi-phenomenon common to certain phases of this, as of other, affections.

This view is clearly untenable, that is, if the description of the cultivation, isolation, and reproduction of the disease from the second and third generation is to be credited. And if, for the sake of argument, we may be inclined, and with justice to criticise strictly the descriptions of the authors of abstruse discoveries, still, I think everybody who believes in the researches of Pasteur with reference to charbon, must, to be rational, also accept the discovery of Koch. A great man of science—Cuvier—once said that on the whole he found it correct to accept rather than cavil at the conclusions of those who had given any subject their undivided attention. But the contagiousness of consumption, no more than the contagiousness of cholera or leprosy, or the exanthemata, does not rest, nor is it dependent on the discovery of any special bacillus. Such a discovery demonstrates and substantiates for the sake of the incredulous what was always the accepted creed in tropical countries where the catarrhal element is not so powerful a factor of complication, and I myself have, from observation, arrived at the same conclusion, and predicted the discovery of a specific germ of a bacterial character (a) long before the profession was made familiar with the bacillus of Koch. The discovery and isolation of which microscopical atom—shorter than the diameter of the red cell—disposes of the objection of Tappinger and Schotellus, as regards the injection of non-tubercular matter, and even *cheese* was followed by tuberculosis in rabbits, which I have always explained in two ways, first, as proving too much, and second, by the action of a non-specific irritation, calling into activity this latent disease to which rodents are peculiarly liable.

With these remarks rendered necessary to place the subject in its proper light, and to prevent disappointment to those who might be disposed to expect too much from the treatment I propose, I will now proceed to show how I was led to try the inhalation of sulphurous acid.

In reviewing the regions of immunity from consumption, particularly Iceland, where, in spite of an adverse climate, complete immunity—on undoubted authority—exists not only among the natives, but among the children of foreigners with an inherited taint, I was struck with the geological formation of the country. The island is remarkable for its volcanoes and beds of living sulphur, which are scattered over a great portion of the land, and, unlike the Sicilian sulphur mines, the deposit of past geological ages are on the surface of the earth in a state of constant sublimation and great purity, the deposit being renewed as soon as removed.

(a) See "Consumption as Contagious Disease," Page 28, &c.

It thus mingles with the air, and is in the most favourable state to bring its influence to bear on the virus of tuberculosis.

Iceland may be described as the sole lowland subarctic region of immunity. The torrid regions of immunity being found on the upland or mountain plateau of Central America—regions, according to Humboldt, abounding in volcanoes, many of which, owing to some subterranean connection, are always in a state of eruption, belching forth sulphur and pitchy stone. Again, in the upland of Mexico, the same conditions has existed for centuries, and Prescott tells us that Cortes, having destroyed his ships before advancing into the country, found sulphur to make his powder by sending his soldiers in buckets down the craters of volcanoes. Thus the Arctic lowland and the torrid mountain regions of immunity, so dissimilar in all respects, agree in the one point of sulphurous formation of the soil. Sulphurous acid is also, as all are aware, useful in the treatment of parasitic diseases—either of the animal or vegetable character—and I have used sulphur vapour in cholera with considerable advantage.

For these reasons I have lately tried it in pulmonary consumption, and with advantage, though at first discouraged by reason of its irritative properties and obnoxious odour. Since, however, combining it as follows, these difficulties have passed away. These preparations may be had from Mr. Bullock, of Hanover Street, and are:—

- 1st. Vapor acid sulph. c. pini.
- 2nd. Vapor acid sulph. c. eucalyptin.
- 3rd. Vapor acid sulph. c. benzoini.

The first contains sulphurous acid dilute, oil of pine, and kaolin; the latter to assist in forming a mixture. The second contains the acid with the oil of the *Eucalyptus globulus*; this latter ingredient answers the purposes of carbolic acid without its disagreeable odour. The third contains sulphurous acid, with benzoic acid or compound tincture of benzoin. These inhalations may be conveniently dropped on a bit of sponge in a wide-mouthed bottle, or used in an inhaler with hot water, or dropped on a little cotton wool in a respirator, or placed in the nostrils. The latter mode will render superfluous the large hideous instruments that cover both nose and mouth.

Other substances may be used in combination, as, for example, iodide of sulphur and permanganate of potash, as well as any sedative that the peculiar symptoms might at any time suggest. The eucalyptus combination I have found especially useful, and, as an example, I may bring forward the case of a young lady who, last October, was in an advanced stage of hereditary consumption, with hæmoptysis, a cavity, extensive crepitation, and high temperature, who is now well under the influence of the eucalyptus and benzoic combination treatment. This patient, unless for a fortnight, was never out of London. Counter-irritation, with aconite to control acute exacerbation, were occasionally applied. Quinine was also given, but no cod-liver oil.

On a future occasion I hope to return to this subject with the result of the trial of permanganate of potash and iodide of sulphur, together with a more extended experience of the sulphurous acid treatment.

ON THE CHANGES PRODUCED IN THE SECRETION OF MILK UNDER THE INFLUENCE OF CERTAIN DRUGS.

By PROFESSOR STUMPF.

Translated from *Deutsch. Archiv. f. Klin. Med.*, Bd. 30, Heft. 3.

By J. E. BURTON, L.R.C.P. Lond., M.R.C.S.,
Physician-Accoucheur to the Liverpool Lying-In Hospital.

DRUGS are capable of influencing the secretion of milk both in relation to its quantity and its quality.

With regard to the first, Röhrig, amongst others, found that medicines that increase blood pressure, such as strychnine and jaborandi, increase the quantity of the milk secreted; whilst the administration of such as diminish blood pressure, such as atropin, bromide of potassium, and chloral hydrate, diminish it. These changes in the secretion last only so long as the drug employed continues its action on the vascular system. As this action is mostly of a transitory nature, it is possible, that notwithstanding a temporary augmentation or diminution in the quantity of milk secreted, that there may be no change whatever, or but the slightest in the day's supply. As substances that check the milk secretion are reckoned iodine, belladonna, quinine, and alum; as milk excitors, the leaves of the *polygala vulgaris* and of the castor-oil plant.

The qualitative changes produced in the milk under the influence of drugs may have relation to its constituent parts, as the fat, milk-sugar, or casein; or may consist in the passing over of the particular drugs in a decomposed or undecomposed state into the milk. Concerning the first-named of these changes but scanty information is before us. It has been represented by Vernois and Becquerel that under the action of mercury the milk becomes richer in fat but poorer in sugar. But, on the other hand, statements as to the passing over of medicine into the milk are very numerous. Thus it was early observed that organic colouring matters, such as saffron, rhubarb, indigo, madder, &c., appear in the milk; that the odorous particles of many plants, such as garlic, onions, camomile flowers, as well as other organic substances used as dressings, as camphor and oil of turpentine, can be detected in the milk. There have, moreover, been found in it foreign fatty matters, originating in the food taken, such as linseed oil, olive oil, rape oil, besides substances taken as medicines, such as aloes, opium, scammony, iodine, zinc, bismuth, boracic acid, arsenic, lead, antimony, and mercury.

But data are wanting as to the quantities of these substances that are to be found in the milk, as to the form in which they are met with, and as to the possibility of a change in the glandular activity due to them. These lacunæ the author fills up as far as regards some of these substances in the above exceedingly exact work. The substances, the actions of which have been investigated, are iodide of potassium, alcohol, lead, salicylate of soda, morphia, and pilocarpine. For this purpose he made use of a goat, 52 kilos. (104 lbs.) in weight, that had lambed ten weeks before the institution of the experiments, and some wet nurses.

On the day after the administration of iodide of potassium (5 grm.), there followed a not inconsiderable diminution in the quantity of milk, the fat increased, but the sugar-rate was diminished. Other oscillations in the proportions of these two constituents took place during a period of eight days, during which 5 grms. of iodide of potassium were daily exhibited. The total of the fat constituents was under the mean, the sugar-rate rose uninterruptedly, and the albuminous substances underwent a rapid increase.

From these experiments it follows that iodide of potassium produces a disturbance in the gland function, and that in consequence of this, fluctuations in the proportions of the various constituents are set up. The contained iodine of the milk increases steadily so long as the iodide of potassium is administered, and in the human species ceases at once on its discontinuance, but in herbivora more gradually. The iodine in human milk is in a relatively higher proportion than in goat's. The therapeutical employment of iodised milk is to be rejected, as the quantity of the contained iodine is subject to such great fluctuations. Iodine *why* is a somewhat doubtful preparation, as the iodine is apparently exclusively excreted in combination with casein, and not as iodide of potassium in solution.

After exhibition of alcohol and beer, the quantity of

the day's secretion of milk undergoes no change; but after the use of alcohol a very decided, and after beer a somewhat less, increase of contained fat sets in; whilst after alcohol, albumen and sugar suffer rather a diminution in quantity, but after beer the sugar is not inconsiderably increased. These changes cease immediately these substances cease to be administered. The author was not able to detect alcohol in the milk, even after the administration of large quantities; and in the same manner some of the products of incomplete alcoholic oxidation were wanting, particularly acetic acid.

He, however, considers the possibility of some small quantities of alcohol passing over into the milk. The sleepiness of some children fed on spirit-drinking nurses may possibly depend on the action of the kinds of ether that resist combustion, or of amylic alcohol that is constantly present in brandy.

After the administration of lead (acetate) the quantity of milk underwent no change, and the changes among the constituent parts were so trifling that they might be looked upon as accidental. The quantity of lead passing over into the milk was very small, but the metal could be detected sixty hours after the exhibition of the last dose.

For this reason the milk of women who are exposed to the action of lead, or who have recently suffered from chronic plumbism, should not be used for children.

Salicylate of soda produced an increased supply of milk, the increase continuing after the suspension of the drug. With the exception of the sugar, the quantity of which was increased, there was no change worth naming in the proportions of the milk constituents. Spontaneous curdling of the milk was prevented by the drug, owing to the increased alkalinity produced by it. The salicylate only passes over into the milk in small quantities, notwithstanding that large doses of the drug may be administered. Morphia produces neither quantitative nor qualitative changes.

After the introduction of pilocarpine rather a diminution than an increase set in; and the relative proportions of the various constituents were scarcely altered at all, only the sugar was increased to a small extent, but the increase was constant.

Clinical Records.

A LARGE PSOAS ABSCESS TREATED ANTISEPTICALLY—RECOVERY.

Under the care of J. C. HALL, M.B., Monaghan.

A. B., *et. 30*, unmarried, a sturmount-looking woman, with family history of phthisis, and who herself had a finger amputated some years ago for scrofulous disease of one of the joints, was admitted into the workhouse infirmary on December 1st, 1881, suffering from a large psoas abscess. For the last few months she has suffered constantly from a dull aching pain in lumbar region and great pain in her back, so much so that she was hardly able to walk. She did not notice any swelling until August last, when she first became aware of a small soft swelling below Ponpart's ligament. On examination I found great fulness in left lumbar region, in which fluctuation could be distinctly felt. The abscess extended downwards to lower third of thigh, and was showing signs of pointing through suppurous opening, where a small bubo-like swelling had formed, about the size of a hen's egg; this had already begun to ulcerate; it communicated with the main abscess. She had slight lateral curvature of spine, and second and third lumbar vertebrae prominent and painful on pressure. Heart and lungs healthy. Menstruation regular, but very scanty of late. I ordered her to bed and gave cod liver oil and syrup ferri. phos.

Dec. 6th.—Having first washed the leg well with carbolic lotion, I drew off from the lowest part of abscess with the aspirator 69½ ozs. of healthy pus; Before withdrawing the

needle I placed a piece of lint soaked in carbolic oil around it so as to prevent the contact of air with the wound. I withdrew the needle and dressed with carbolic oil and salicylic tow and bandaged the leg firmly. Her temperature on the morning of operation was 99° F. The measurement round centre of thigh was 24 inches before, and 21 inches after, operation.

8th.—Removed dressings; wound quite healed; no rise of temperature or any constitutional disturbance.

14th.—Doing well; applied a poro-plastic jacket to her back. She menstruated on the 9th.

17th.—Tapped again, drew off 25½ ozs. of healthy pus, and dressed as before.

24th.—Have had some trouble with the small tumour in groin, it having at last opened of itself, and discharged a small quantity of serous-looking fluid, containing white flaky substances, which are so often seen in abscesses of this kind. It did not communicate with the main abscess, the opening having become occluded when the sac contracted. However, it is now almost healed and not discharging. She went home for Christmas.

Jan. 3rd, 1882.—Was re-admitted on the 1st. Tapped again and drew off 16 ozs. of serous flaky-looking fluid. This was the third and last operation, making in all 110½ ozs. of pus drawn off with the aspirator.

Feb. 6th.—Has been doing very well, and has gained 10 lbs. in weight during the last month. One of the needle wounds has opened and discharges some serous fluid every third or fourth day. I keep the opening well covered with carbolic oil and salicylic tow, thus preventing any septic action taking place. She left hospital to-day in good health and spirits.

I did not see her again until 5th of June. Sinus quite closed and pain in back gone, though she still wears the poro-plastic support. Says she feels better than she has done for more than a year, and can walk several miles without fatigue.

I look upon this case as interesting in several respects. It shows the value of the method recommended by Mr. Abernethy, of evacuating by a small incision, getting the wound to unite by first intention, and opening again when cyst fills, thus letting its walls contract gradually and lessening the danger of hectic, which so often follows operative interference with lumbar abscesses.

In this case I had an extra danger to contend with in the small swelling in the groin, which fortunately did not open until its communication with the main abscess was closed. I consider salicylic tow a most useful, indeed I might say necessary, adjunct in the treatment of these cases; it can be used as a compress, and prevents the discharge, which makes its way through nearly every kind of dressing, from becoming septic, especially when the wound is in the groin or thigh. I saw it first used by Dr. E. H. Bennett, of Dublin, with great success in a similar case.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

ANTISEPTICS IN THE TREATMENT OF TYPHOID FEVER.—At the meeting of the Académie de Médecine M. Vulpian read a report on the relative value of the different so-called antiseptic agents in the treatment of typhoid fever. M. Vulpian, in his service at the Hotel Dieu, had abundant opportunity of testing the efficiency of the drugs in question. Iodoform gave him no good results. Salicylate of bismuth is an excellent antiseptic, but it was insoluble, and the dose had to be greatly increased. Boric acid, although administered at the dose of three drachms daily, was not attended with any appreciable effect. It was quite otherwise with salicylic acid. M. Vulpian employed this acid at the dose of ninety grains a day, given in divided doses of five grains every half-hour. Under the influence of this treatment the temperature fell considerably in forty-eight hours. At the same time a very sensible amelioration in the general state of the patient was observed. The effects of the acid, however, are limited to these phenomena; the duration of the disease or the mortality are in no wise affected. The

phenate of soda is an excellent antiseptic, but it is impossible to accumulate in the blood a quantity sufficient to destroy the toxic principle. In conclusion, and having passed in review the different agents employed in the treatment of typhoid fever, M. Vulpian pronounced in favour of salicylic acid.

ERGOT OF RYE IN THE TREATMENT OF TYPHOID FEVER.—M. Martineau read a communication from a colleague on the efficacy of ergot of rye in the treatment of typhoid fever. The author based his observations on the number of cases treated by him in the past seven years, and has come to the conviction that ergot of rye is, up to the present, the best remedy against all forms, and especially the gravest forms, of typhoid fever. He tried many other drugs, but none of them gave him such good results. Since the splendid discoveries of M. Pasteur, which gave us the true etiology of charbon in animals in demonstrating the existence of bacterides, medical men are endeavouring to emulate the eminent chemist, and are vying with each other in their endeavours to discover similar causes for the virulent diseases of man. Syphilis was the first to engage attention, and although all researches for bacteria or microbes made up to the present in Germany, as well as France, were unfruitful, M. Martineau was not to be deterred from prosecuting more minutely his experiments with a result which he considered eminently satisfactory and conclusive. His report will be made known next week.

MENINGITIS SUCCESSFULLY TREATED.—At the congress held at La Rochelle, and styled, "Association Française pour l'Avancement des Sciences," M. Vovard, of Bordeaux, gave nine cases of meningitis successfully treated. Five of the children were treated after a method of his own, which he would have the honour of laying before the assembly, as soon as the diagnosis of meningitis was made. He prescribed the iodide of potassium, he has the head shaved, and spreads, by means of a hair pencil, over the whole shaven surface, a slight coating of croton oil, applying subsequently a bonnet of oil-silk to prevent absorption of the irritant by the clothes. This dressing is renewed twice a day until a good and abundant pustular eruption is obtained, when the croton oil is stopped, an irritant pomade is applied, and the suppuration continues. He insisted greatly on the necessity of procuring a prolonged and abundant suppuration. The relative frequency of cures in this disease made him inclined to believe that in a large number of cases the meningitis of children was not of a tuberculous nature, but depending on a strumous diathesis. Another member called the attention of his colleagues to the importance of injecting concentrated acetic acid into and around cancerous tumours, so as to saturate them with the caustic. He cited two cases in which he had recourse to this method. The first, epithelioma of the lip, was entirely cured, and for eight years, or until the death of the patient, there was no sign of a return. The second was very characteristic; it was epithelioma of the tongue, and was treated first by the thermo-cautery, but returned in a month. The acetic acid in a concentrated form was now used in interstitial injections, and caused great pain after each operation. After the third operation the effect of the acid was manifest, and in four days the tumour became detached. Three months have passed, and no sign of a return. The treatment in any case is worth a trial, as there is never any excessive hurry with the thermo-cautery. The pain, which, as we have been told, is exceedingly severe, could be materially lessened by large doses of chloral.

MORPHIOMANIA is becoming alarmingly prevalent in France, and examples are to be met with in every class of society. Amongst the ladies the little silver syringe is an indispensable article of their toilette. Whenever they are put about, recourse to that little machine—which they handle very dexterously and scientifically—settles everything all right; the self-inflicted torture is more than compensated by the results. It is sad to have to say, and entirely incomprehensible, that the whole cause of this demoralising and ruinous habit must lie at the door of medical men. However, it is so. The French doctor would no more dream of leaving his house in the morning without his hypodermic syringe than he would without his hat; and, indeed, the former is considered by him by far the most indispensable. The patient has only to say where he has a pain and a *piqûre de morphine* is immediately made. The next day the operation is repeated, and every day as long as the patient complains. It is needless to add that it is done more often than the occasion requires; but if the medical attendant always administered the drug himself perhaps the evil would not extend beyond the convalescence of the patient, but, unfortunately, such is far from the case. It is the habit of doctors, so little do they think of the danger, to recommend to a patient attacked with a chronic disease, such as sciatica, to buy a Pravaz syringe for himself, and to use it, whenever the occasion required, at least once a day. The results are easily foreseen. There are numbers of medical men themselves who have fallen victims to the alkaloid. There is no doubt that morphia in subcutaneous injection affords a precious resource to medical attendants for the allaying of acute suffering, but it is not the only agent capable of producing an immediate cessation of pain. Ether, chloroform, atropine, and even simple water, have been proved to have equally as good an anodyne effect, when used subcutaneously, as morphia, and with the advantage—which cannot be considered an unimportant one—of not being attended with a deleterious effect on the constitution from prolonged use, except, perhaps, in the case of atropine. It would be well if medical men took into serious consideration the ill-effects which invariably follow a careless, and often needless, use of the syringe, and apply their influence to warn their patients against a danger no less formidable, as regards society and themselves, than alcoholism, a plague which is rapidly on the increase, and in a country where hitherto it was almost unknown.

EPIDEMIC OF MEASLES.—At St. Etienne (Loire) there is an epidemic of measles, producing a great mortality amongst the children. Pneumonia and diarrhoea are the chief complications which cause a fatal result.

Special.

HEALTH OF THE NATIVE ARMY OF INDIA.

FROM official sources we learn that during the four years previous to 1880, a steady and progressive rise had been in progress in the rate of mortality among the native force in India. Thus, whereas in 1877, the rate of death among them was only 13.33, it has risen to 41.12. In respect to two classes of disease there was a decrease in the admission and death-rates as compared with 1879, namely, intermittent fevers and cholera. The latter scourge was confined almost exclusively to Bengal, the total deaths by it throughout India falling from 558 in the previous year to 67 only in 1880. And yet notwithstanding the decrease in deaths by these affections,

there has been a general rise in that of mortality from all diseases, from 1877 as first stated, and from 1879 of from 37·79 to 41·12. It is stated that no one particular disease proved unusually fatal, but that a general rise took place in the more ordinary and fatal maladies. Thus, respiratory diseases, the death-rate of which stood at 2·12 in 1877, had run up to 10·00 in 1879, and 12·30 in 1880; the death-rate of fever, other than intermittent, increased from 1·91 in 1877, to 6·73 in 1880; and in bowel complaints a notable increase took place. A notable cause of the increased death-rate was the greater number of men who fell in action, namely, 908 in 1880, as against 342 in 1879.

In the Bengal Regular Native army the rate of admissions per 1,000 strength was 1,737, of deaths, 51·39, or excluding Afghanistan 1,609, and 33·85 respectively; Madras, 1,399 admissions and 15·57 deaths; Bombay, 1,455 admissions and 56·97 deaths, or excluding Afghanistan, 1,283 admissions and 10·44 deaths. In cantonments generally, throughout India, the increased rate of mortality shown, chiefly occurred in Bengal, the death-rate in that Presidency having advanced from 10·32 in 1879 to 33·85 in 1880, the chief causes of the increase those already stated. The circumstance also has its significance that among the British troops the death-rate 27·73 was considerably below that of the natives. At certain stations, the cases of sickness and mortality were particularly high. Thus at Barrackpore, the 36th N.I. lost a ratio of 163·63 per 1,000 strength as against 64·43 in 1879. In 1878 however, the 38th N.I. lost, at this once favourite station, a ratio of 264·35, the great majority of deaths being due to ague, dysentery, diarrhoea, and their results caused by prolonged residence in unhealthy situated barracks. The Delhi Field Force lost 91·01, and the 42nd N.I., stationed in Upper Assam, lost 70·69, chiefly by anæmia, cholera, fevers, and bowel affections. Among Madras troops occupying cantonments the death-rate was 14·7. At a few stations, however, results were less satisfactory, thus at Rumpah, the rate of admissions was 4,274, of deaths 62·88, at Rarjamunday 4,268, and 43·03, at both chiefly by fever and bowel complaints. On the other hand, at Bangalore the admission rate was only 810, and at St. Thomas' Mount, as low as 510. But statistics gave far other results in regard to Madras regiments sent to Bengal to replace corps thence ordered on service: thus the 1st M.N.I. at Fort William gave admission and death-rates of 2,414 and 45·85; a Madras regiment at Mooltan lost 35·66 of its strength.

With regard to Bombay troops remaining in cantonments the admission rate was 1,283, that of mortality 10·40. The highest admission rates occurred at Ahmenahad and Ahmednuggur, they have been at those stations 1,884 and 1,726 respectively. The highest rate of mortality, namely 19·91, occurred at Aden.

With regard to native forces engaged in active service the rate of admissions was 1,964 and 82·24, against 2,380 and 84·95 respectively for 1879. Of the above death-rate only 3·88 was due to casualties in battle and otherwise, out of hospital. Bowel affections furnished 38·25 per 1,000 strength out of the total mortality, the other most fatal diseases being evers and lung affections, the two latter being twice as fatal as the same affections in cantonments. There was a decrease of 12·58 in deaths by cholera as compared to 1879, but that respiratory diseases increased by 10·80 per 1,000 strength; this great increase being assigned to inability on the part of the native Indians to withstand climatic influences in Afghanistan.

In respect to certain divisions of the active army, the statistics are very suggestive, and indeed sad. Thus, in the

Khyber Valley the death-rate in the native forces equalled 105·94 per 1,000, among the British 71·43; in the Kurrum Valley among natives 42·03, British 49·0; but while the former lost "by violence" only 7·98, the latter lost 22·07. For the eight months in Cabul, the mortality among native troops was 28·81, among British 18·87.

Of the Madras army only a strength of 1,512 took part in service in Afghanistan. The statistics in reference to them show a rate of admission equal to 1,211; of mortality 31·03, thus indicating far more favourable results than among the more northern native troops of the larger Presidency.

With regard to Bombay troops on service, the general death-rate was 134·10 per 1,000. This general high rate is however accounted for by the large number of men belonging to this Presidency who fell in action, namely, 625 at Maiwand, and 64 at Deh Kojah. Deducting these numbers there remains a loss by disease equal to 79·47 per 1,000.

ALLEGED MALPRACTICE IN AUSTRALIA.

At the present time, when scarce a week goes by without adding at least one name to the long list of those who have been rightly prosecuted and punished for imposing themselves on the public as duly qualified medical men, any account of alleged incompetency in regard to members of the profession will not be without interest. In this connection a case has recently been concluded in Australia, the particulars of which cannot be allowed to pass unnoticed. In the action, which commenced at Sydney on June 12 and terminated on June 15, Dr. Alexander Stark Ogg, M.B. Toronto, L.R.C.P. Edin., and M.R.C.S. Ontario, was sued for £3,000 by a man and his wife, the damages being demanded as a set off against loss and injury asserted to have followed in consequence of Dr. Ogg's unskilful treatment of the female plaintiff during and succeeding labour. The facts of the case unmistakably point to one conclusion—viz., that Dr. Ogg brought a most difficult and dangerous illness to a successful convalescence; and this opinion was expressed in the verdict of the jury, by whom the defendant was declared not guilty.

Dr. Ogg's attendance on the woman commenced at a time when she was experiencing early labour pains; delivery was difficult and protracted, and after due time and effort, was effected by forceps. For a day or two all

went well, but ere long puerperal fever set in, and at one time a temperature of 107 and pulse of 140 were recorded. During this critical period Dr. Ogg was unremitting in attendance, and by his prompt and sound treatment he undoubtedly preserved the patient's life. She did not, of course, get well at once, but the fever was followed by phlegmasia dolens; this distressing malady, however, was likewise yielding to skilful treatment when she appears to have fallen into the hands of a "Dr. Marshall," who described himself as M.D. of the Coll. of Med. and Surg., Cincinnati, U.S.A. This gentleman is an admitted rival practitioner of Dr. Ogg's, and, as the only witness in support of the claimants at the trial, favoured the court with some very remarkable evidence. He diagnosed the case when "called" to it on September 15 (the last day on which Dr. Ogg saw it) as *uræmia*, and from a microscopical examination of the blood determined that the white corpuscles equalled in amount one-third of the red. From the ankles he obtained a watery serum containing (likewise determined by the microscope) crystals of uric acid, and the presence of urine in this situation was explained on the ground that it had "dropped down into the legs." The evidence of this practitioner was altogether unreliable, and displayed such ignorance that there could be no question of his utter incompetency in a professional sense. On the other side ample and unimpeachable testimony, supplied by highly qualified medical men, gave indisputable evidence of the skill with which the female plaintiff had been treated; and the case naturally ended to the satisfaction of professional honour.

We have said that this case occurred in Australia, and, unfamiliar as we are with any parallel to it in this country, we may with advantage inquire how it could possibly have arisen. Without desiring to insinuate anything which we are not entitled to suggest, it is impossible to avoid the suspicion that jealousy of a brother practitioner has had some part to play in the drama, and that at least one person claiming rank as a medical man would have hailed the downfall of the defendant. It seems but reasonable, then, that Dr. Marshall's credentials should have been made the subject of investigation by the court to which, in reality, he appealed against another practitioner, for he directly impugned the latter's skill and knowledge. Every attempt, however, to ascertain the worth of his degree was foiled by the obstinacy with which he refused all information about it, alleging in excuse the fact that the New South Wales Medical Board had the matter under investigation.

This Medical Board is in some sort a copy of our own "Council," and apparently almost as useless. In each of the Australian colonies medical practice is regulated by a Medical Board, the licence of which is necessary to everyone calling himself a practitioner, and which, moreover, is empowered to punish all pretenders, a fine of £50 being possible on conviction. The samples we get in London from time to time of Australian quacks, one of the most unblushing of the tribe being at this moment in practice in a principal West-end street, speak but little for the stringency of the "Board's" regulations; and from what we occasionally see and hear of

the doings of rogues in this country and Australia, we cannot help the thought that if one blow swept away our Council and their Board it might do some real good to the profession.

Suits for malpractice against duly accredited medical men are so rare that we may safely ascribe them to the jealous instigation of rival practitioners, who can lose nothing, but may gain much from the result. Nor is it difficult to convince oneself that the active exciter of the proceedings is often open to suspicion regarding the *bond fides* not only of his motives, but of his qualification as well; from which it is but a short step to the conclusion that an honourable practitioner would be among the last to impugn the professional conduct of a professional brother. This ought to be; here, at any rate, we believe it is so.

In a recent trial in London, an unqualified assistant was tried and found not guilty on a charge of manslaughter, the principal evidence against him being that his diagnosis of a certain case was contradicted by post-mortem examination of the patient. The question arises whether a charge of malpractice with a claim for damages maintained in a civil court might not successfully be urged against every unqualified assistant who misconducts a case; and how many such there are each day it would be difficult indeed to estimate. Were the proceedings we have mentioned as taking place in Sydney imitated in London in those instances only which the various associations for protecting medical interests could easily bring forward, we venture to think the pocket principle thereby invoked, would do more in a short time to check the unqualified assistant system than a long course of such action as is being taken at present.

THE LONDON WATER SUPPLY.

QUITE recently a paper has been published in the shape of an official Report by the Thames Conservancy Board, and from it we learn that, in consequence of the efficiency and activity of the Board during the past fourteen years, the Upper Thames, whence the Water Companies take their supplies, is now "practically free from sewage contamination." This, an old cry revived, is still a very long way from the truth. From personal inspection made during the past summer months, we are in a position to say, from a sanitary point of view, that only some very slight improvement in this respect has taken place. The last census showed that nearly one million of people reside on or about the drainage grounds above the intake of the water companies, and the whole of this vast mass of human beings send sewage more or less directly into the Thames. A slight alteration between the fluid and solid contents of the sewage we admit has taken place. What in former days was collected in covered cesspools, or sent through drains directly into the river is now intercepted, pumped into reservoirs, and there treated chemically, after which the liquid portion is allowed to flow into the river, whilst the more solid portion is used as manure, that is, spread over the adjoining land, and in consequence a good deal of this is washed by rains back to the water-shed. In other cases the sewage is strained

off by being passed directly over land, sewage farms, and the whole of the fluid portion then passes directly back into the bed of the river. A tolerably large proportion of the solid matters find their way back to the Thames, as in former times, and mainly by the action of storms and rain. In either case, all the liquid portion, holding in solution the urinary salts and the albuminoid ammonia, of which consists the chief nourishment of infective germs, the dreaded bacilli of typhoid and cholera, finds its way back to the river in as dangerous a state as it is possible to conceive, much in the condition it was before the Thames Conservancy Board attempted to exercise control over the Thames. Indeed, we are assured by competent water engineers that more sewage now finds its way into the river than a few years ago. The solid contents of the sewage which under the cesspool system was deposited and became a solid mass at the bottom of these receptacles is by the intercepting methods more effectually mixed up with the fluid portion and sent into the river, thus contaminating the water to an alarming extent. So much for the fool's paradise into which the Thames Conservancy Board would lead the public. On the other hand, the "water examiner" would have us believe that this liquid poison is made pure by "efficient filtration," and that "a standard of purity" may be fixed by straining Thames water through a few layers of sand and gravel, about the arrangement and thickness of which no two companies are perfectly agreed. For instance, the Grand Junction is content with four feet of the two ingredients, the Southwark and Vauxhall five feet, the Lambeth seven feet, the Chelsea eight feet; the West Middlesex has no measure, and so it comes about that the water examiner has been unable to fix the water companies with anything like what he terms "a tentative standard rate of filtration;" but he is quite sure the water should not pass through the sand and gravel filter bed at a greater rate than 540 gallons per square yard in the twenty-four hours. So that what the Conservancy Board and filtration may be said to have done for us is simply to convert thick soup into thin; and so the London water supply remains as of old, an unceasing source of danger to the public health.

THE IMMOLATION OF AN IRISH POOR-LAW MEDICAL OFFICER.

A FORTNIGHT since, we gave in the Supplement which we specially devote to Irish Poor-law affairs a narrative of the sacrifice of an Irish workhouse medical officer by the personal spite of his board of guardians—the transaction being under the immediate patronage of the Irish Local Government Board.

Dr. O'Reilly, of Lismore, in the county Waterford, had served for 13 years without any charge whatever against his efficiency or his willingness to perform his duty until one day he became involved in a brawl along with the master of the workhouse and the nurse. Whose fault the wrangle may have been we know not, but a sworn investigation thereon declared that the harmonious working of the establishment was at an end, whereupon the guardians, seeing their opportunity to get rid of an unpopular medical officer, called upon him to resign, but allowed

the master and nurse to remain in office. Considering that, if any one was entitled to use strong language it was certainly not the subordinate, and considering that the Local Government Board themselves on the report of their inspector expressed officially the opinion that there was no reason for making a distinction of punishment in favour of the master or nurse, we certainly hoped that that Board would have exercised the authority specially confided to it for the protection of its officers, and would have refused to endorse the dismissal of the medical officer, in which the board of guardians, for personal reasons, persisted. But we were mistaken in crediting the Irish Local Government Board with this much firmness or fairness, for not only did that Board not protect the medical officer, but it went out of its way to hint to the guardians that they might get rid of him comfortably by suspending him, though they had no power to dismiss him.

In view of that suspension, and of the risk which he would run of losing his dispensary appointment, in case he was dismissed from the workhouse surgeoncy, the medical officer submitted to injustice and resigned.

The full details of the case will be found in the Supplement to our last issue, and, as we are now about to discuss the principle, we will not further touch the circumstances, except to say that, so far as we can find out from perusal of the sworn evidence, no cause whatever existed for treating Dr. O'Reilly as incapable, unwilling, or unfit for his office. We are fully satisfied that he has been "got rid of" by the guardians because he was personally unpopular with the voting majority of them, and that his unpopularity arose in a great measure from his having more than once found it necessary to make complaint of certain matters of workhouse administration. Certain it is that Dr. O'Reilly has never been guilty of anything which his enemies could formulate into a charge worthy of investigation, and that he stands to-day untainted by any fault whatever which affects his competency for office, or, indeed, by any other fault than the heinous one of not being, in the eyes of the guardians, a "jolly good fellow."

Now we are not at all interested in the defence of Dr. O'Reilly personally. He has—perhaps of necessity—purchased his own safety by submitting to a gross injustice, and in so doing, he has conceded to the board of guardians a principle which, in the interest of Poor-law officers generally, ought to have been contested by every possible means. By his resignation of his office he has acknowledged the right of the guardians to get rid of him because they do not like him, and has relieved the Local Government Board from the dilemma in which his refusal to resign would have placed them. Therefore we have, speaking for the profession, nothing to thank Dr. O'Reilly for, but there still remains open to dispute the conduct of the Irish Local Government Board.

For the first time that Board has taken up the position that it is none of its business to interfere for the protection of its officers if the board of guardians under whom that officer acts pleases for any unknown cause to thrust him out of office. The Local Government Board has, in fact, degraded the medical officer from his position as a civil servant of the Crown acting under the superintendence of the local guardians, to the position of a domestic servant

to whom the guardians may "give warning" at any moment that their caprice may dictate, and it has practically declared its determination not to embroil itself with any board of guardians who may please to change their officer for one more pleasant to their ideas. From this interpretation of its act the Irish Local Government Board has no escape, for it has already pinned itself to an official acknowledgment that Dr. O'Reilly did not deserve exceptional punishment. Having thus publicly declared that the contemplated act of the guardians was unjust and improper, the Local Government Board was surely bound to withhold its official sanction to the act, but instead of adopting this course, it sought to relieve itself of responsibility by encouraging the guardians to do the dirty work of virtual dismissal. And why? Because the Board well knew that the guardians had no power to dismiss—that, if the medical officer refused to resign, the act of removing by sealed order an officer whom they had officially declared to have done nothing worthy of exceptional treatment, would fall, with all its moral, legal, and Parliamentary responsibilities, upon the Local Government Board itself. To save itself from this difficulty, the Board said to the guardians, "You cannot dismiss, but you may suspend," and thus they escaped from their cowardly and discreditable position by frightening the medical officer into a foolish resignation.

The Local Government Board for Ireland has all the honour which its diplomacy deserves. It has shown considerable knowingness in shuffling out of its duty in a way that a firmly and justly administered public department would not have condescended to do. It has advertised to all the boards of guardians and dispensary committees in Ireland that it is willing to oblige them in every way—legal or illegal—if they have a desire to clear out a Poor-law officer; and it has given warning to all such officers that they had better keep in favour by hook or by crook with the ruling of their guardians, for they differ only from domestic servants by not enjoying the cook or housemaid's privilege of a month's notice to go.

We do not doubt that the Local Government Board and the board of guardians would—if they dared speak the truth—excuse themselves by saying that Dr. O'Reilly was an unpleasant person, and, as the phrase goes, "a troublesome fellow." We think it likely he was. Every medical officer in Ireland who is not of the politico-religious colour of the majority of his guardians is—to them—an unpleasant person; and every active, conscientious officer who tries to improve his district or get rid of old abuses in his own department is inevitably "a troublesome fellow." The term is one of laudation rather than of opprobrium; but, if it were not, we utterly protest against the sacrifice of a medical officer for any reason whatever which does not see the light. We hold the opinion—which the Local Government Board will no doubt consider ridiculous—that a medical officer has his rights as well as his duties; that he holds his office *dum bene gesserit*; and that no board or person whatever has any legal or moral right to deprive him of his position without sufficient cause publicly shown. Therefore we regard Dr. O'Reilly's removal, and every other suspension or dismissal which is actuated by any cause whatever

which cannot be publicly justified, as a tyrannical abuse of power by the strong against the weak.

We do not intend that the proceedings of the Local Government Board shall drop out of notice, and we hope that, when Parliament assembles, some member of the House who values liberty and justice will drag before the opinion of the masters of the Irish Local Government Board their very discreditable action towards Dr. O'Reilly of Lismore.

Notes on Current Topics.

A Challenge to Anti-Vaccinators.

WE have received a copy of a letter from Dr. J. B. Mitchell, in which he challenges any anti-vaccinating champion to join him in carrying out a crucial experiment as to the value of inoculation. His proposal is that a properly qualified person, nominated by the anti-vaccinators, shall accompany him to a country where scientific inquiry is not burked by a penal enactment, and that comparison shall there be made of the results produced by small-pox inoculation of recently-vaccinated and non-vaccinated persons. The expenses thus incurred, Dr. Mitchell suggests shall be paid by him and the anti-vaccinators in equal proportions, but that the amount paid by the winning side shall subsequently be refunded by that which is condemned by the experimenta. These proposals have been communicated both to the *Echo* newspaper, and to the high priest of anti-vaccination, Mr. P. A. Taylor, M.P., but have been ignored by both these mainstays of anti-hygiene. The *Echo* has so prominently identified itself with non-progressive principles, and has so vehemently abetted the popular ignorance in all questions of scientific importance, such as vaccination and vivisection that it is easy to comprehend its unwillingness to give place in its columns to any utterance which might possibly excite unfavourable criticism of its pet creeds, or tend to stimulate its readers to a process of reflection very unusual with them. Mr. Taylor, also, is more given to support his craze by words than by acts, for he very well knows that such a proof as that demanded would forever debar him from posing in his present guise, inasmuch as it would effectually ruin the cause he has in hand, and settle every argument in his and his co-agitators' repertoire. Perhaps, however, some of the "medical men" who swell the roll of the anti-vaccinators may, for shame's sake, take up the gauntlet thrown down by Dr. Mitchell.

The Action of Oxygen on the Tissues.

EXPERIMENTS have recently been conducted by Signors Capranica and Colasanti, at Rome, with the object of ascertaining the effects produced on the tissues by oxygenated water. From a note in *Nature*, it appears that the substance acts as a poison, when physiologically absorbed according to Hueter's method, animals dying more or less quickly under it, according to size; a dog, weighing three kilogrammes requiring twenty-five cc., and another of thirteen kilos, seventy-five cc. The poisonous

action appears in all the great functions of the body, but especially in the spinal cord, the excito-motor centres being intensely stimulated, as shown by the use of convulsive phenomena. Nutrition is also profoundly disturbed, death being preceded by very pronounced glycosuria. The consequences observed are attributed by the experimenters to the decomposition of hydrogen peroxide (H_2O_2) in the tissues, and a similarity is traced between the consecutive phenomena and those recorded by M. Paul Bert as following on the action of compressed oxygen on the animal body.

Acute Myelitis with Double-sided Neuritis Optici.

THE following case, which Dr. Henry D. Noyes had under his charge and reported in the *Arch. f. Akde*, x. 3, p. 331, is in so far of great interest, as the issue of the case was remarkably favourable, ending in an almost complete cure:—A minister of the church, 25 years old, and an habitual smoker, but otherwise in perfectly good health, began to suffer first from constipation and then from difficulty in urinating. At the same time he complained of a cold sensation in his lower extremities, and could cross one leg over the other with exertion only. First, vision of the right eye, and, about a week later, vision of the left eye also, became very much impaired. In both eyes, but especially in the right, the inner half of the papilla became swollen and hyperæmic. Besides concentric narrowing of the vision, there existed also a central defect. Large doses of iodide of potassium were given the patient internally, and the neck and back over the spinal column were cauterised. Gradually the patient reached the enormous dose of about five drachms (18 grams) of iodide of potassium per diem, and this medication was continued for fully one month and a-half. The scotoma cleared up totally; two months later both eyes possessed their normal power of vision, and a perfectly clear field of vision had been regained. But occasional giddiness, headache, and some difficulty in micturition, notwithstanding a normal composition of the urine excreted, were still present. In consequence of the favourable issue of the case, it must always be an open question if the diagnosis regarding the seat of the lesion—inflammatory affection of the spinal cord, accompanied by a morbid change confined to the commissure of the optic nerve—was the correct one.

The Sanitary Congress.

DURING the present week the Annual Congress of the Sanitary Institute of Great Britain is being held in Newcastle-on-Tyne, under the presidency of Captain Douglas Galton, C.B. A strong local committee, with Mr. H. E. Armstrong, medical officer of health for the city of Newcastle as chief secretary, has been actively engaged in preparing for the reception of the Congress, which promises to be among the most successful of the many similar gatherings already held this autumn. The three sections of Sanitary Science and Preventive Medicine, Engineering and Architecture, and Chemistry, Meteorology, and Geology will be presided over by Dr. Dennis

Embleton, Mr. Henry Law, and Dr. Arthur Mitchell, F.R.S., respectively, and in each a goodly number of communications will be read on important subjects. In connection with the Congress, also, an exhibition of sanitary apparatus and appliances and articles of domestic use and economy will be held in the Old Tyne Brewery, Bath Lane, closing on Saturday next, on which evening Dr. B. W. Richardson, F.R.S., will deliver a lecture in the Town Hall to the working classes. Numerous excursions and visits to places of interest in and near Newcastle have been arranged, and the lighter entertainments include a public luncheon on Tuesday, a *conversazione* in the Town Hall on Wednesday (this) evening, and a "banquet" in the assembly rooms on Friday. Altogether there is every reason to anticipate a large and successful gathering.

Fraud by a Physician.

At the Middlesex Sessions, before Mr. Prentice, Q.C., Richard Ryan, 35, physician, was indicted for having obtained by false pretences, from Joseph Hill, the sum of £8, with intent to defraud. Mr. Purcell conducted the prosecution; the prisoner was not represented by counsel. The case was rendered a somewhat painful one from the fact that the prisoner had been a brilliant student and was a graduate of Queen's University, Dublin, a L.R.C.P. and M.R.C.S., Edin., as also a L.A.H., Dublin. The evidence showed that Dr. Vickars, who practises in the East India Road, being desirous of a month's holiday, advertised in one of the medical papers for a locum tenens, offering a salary of £10 10s. for the month, with apartments and board. Instead of answering by letter the defendant called personally, and on showing his diplomas was at once engaged. He was instructed to receive fees from the patients and subscriptions from those attending at a local dispensary of which Dr. Vickars was the medical officer, but had no authority to draw or give receipts for any other moneys. It seemed that on August 14th Mr. Hill, the nominal prosecutor in the case, who is a tenant of the doctor, called to pay a quarter's rent, amounting to £8, and the prisoner, representing that he was empowered to receive it, gave a receipt for the sum. In consequence of complaints from many of the patients, Dr. Vickars's sister and the gentleman who acts for him as dispenser telegraphed for him to come home. On his arrival he paid the prisoner the balance due to him and dismissed him. A few days afterwards he ascertained that Mr. Hill had paid his quarter's rent, and the prisoner was then given into custody. In his defence the prisoner pointed out the serious consequences of a conviction, stating that he should be struck off the registers of the various universities to which he belonged, and urged that he had no intention of stealing the money, but that falling into bad company he had lost it. The jury having returned a verdict of guilty, Mr. Prentice, in consideration of the serious consequences of a conviction, passed the lenient sentence of three months' imprisonment.

THE library of the Royal College of Surgeons in Ireland re-opened, after the summer recess, on Monday, September 18th.

Surgeon-Major John Alexander Shaw, F.R.C.S.I.

THE announcement of the death of this gentleman which was published in several journals as having been killed in Egypt is contradicted. The Surgeon-Major Shaw who was killed in action at Kassassin was Surgeon-Major George Shaw, a licentiate of the Royal College of Surgeons in Ireland, and son of a late Dublin surgeon.

Professional Puffs.

WITH reference to our recent editorial notices of a fulsome puff of a Dublin surgeon which appeared in the *Waterford News*, and a report of a surgical operation published in an Enniskillen journal, we have received a letter from the Editor of the Waterford paper to the effect that he "was alone responsible for the publication, having written it without the knowledge or consent of any person." We have also received a letter from Dr. Gamble, who was mentioned as the hero of the Enniskillen case, in which he informs us that the paragraph "was published entirely without his knowledge, and was altogether repugnant to his feelings." We have already expressed our confidence that the surgeon named in this Waterford paragraph was not in any way privy to it, and we are glad to publish now a reclamation which relieves him of all connection with the transaction. It is, however, we think, greatly to be regretted that the responsible conductors of public journals seem, in some cases, to imagine that they are doing a medical practitioner a service by be-lauding him in paragraph. They are, in some degree, to be excused because of the frequency of this offence against professional decency, but, nevertheless, they are entirely wrong in their estimate of the position which the medical profession occupies. Physicians and surgeons are not mere traders, dependent for their character on the amount of newspaper publicity they can attain; they occupy the position of men of science, and gentlemen recommended to the public by their attainments, intelligence, and work, and it is not complimentary to them to suppose that they cannot secure the public confidence without the adventitious aid of newspaper puffs, nor complimentary to the public to suggest that they select an adviser because they see his name frequently in the paper.

We wish it were universally understood by newspaper conductors that they do not serve any medical practitioner by puffing him, but, on the contrary, involve him in suspicions of complicity which are very injurious to his professional character. On the other hand, we hold that the medical practitioner who is the victim of a zealous newspaper friend owes it to his profession to aid in removing from the public mind the idea that newspaper puffery is a legitimate method of seeking medical practice. It is not, in our opinion, sufficient to repudiate the transaction privately, after it has attracted public attention, but, on the contrary, a surgeon who respects himself—if he has reason to fear a paragraph puff—ought to make it understood that he seeks no such honour, and, if it be conferred on him unexpectedly, he ought to hasten to repudiate the proceeding, lest the impression may be created that he connives at the advertisement and accepts willingly the professional profits arising therefrom. We are quite satisfied that neither of the surgeons victimised

on this occasion had anything to say to the puffs of which we complained.

Nerve Stretching.

THE *New York Medical Record* last to hand among exchanges, contains the second part of a highly important and interesting paper "On Nerve Stretching," by Dr. W. J. Chandler. In this communication the author tabulates over 350 cases of diseases treated by the operation, and a study of the results thus presented is certainly most instructive. He has arranged them in groups distinguished by the nature of the pain experienced. Thus seventy instances of operation for sciatica are placed together, and the result in a great majority of cases is given as "cured." Indeed, the best results seem to have been obtained in this affection and other neuralgias, and the least satisfactory in diseases involving the nervous centres. The opinion that must be formed after careful consideration of all the tables, however, is decidedly not adverse to the justifiability of the operation in cases selected with appropriate judgment. Especially is it, apparently in actual neuralgias, that it is most frequently successful, and rarely even where no cure is obtained is some relief at least not gained. Much as nerve stretching has been deprecated, it has undoubtedly been often productive of benefit, and enough has been shown in its favour to encourage somewhat of the feeling which evidently animates Dr. Chandler. Speaking of the future of the operation, he predicts that it will continue to be opposed—"even misrepresented. But while it does not accomplish all that its most ardent advocates claim for it, while, too, there is much to be learnt as to particular modifications of the operation, and their adaptability to different forms of disease, we feel confident that an operation that develops so much statistical strength has certainly enough of real merit to overcome opposition, and stand in the future side by side with ovariectomy, tracheotomy, and paracentesis thoracis in the honoured list of accredited surgical operations."

The Perils of Sanitary Progress.

THE Wigan Corporation, after spending over £62,000 on works for the disposal of sewage by means of a sewage farm, are now the subjects of an action for coal lying under a portion of the pipe line of sewers. The claim is for £22,664 12s. 7d., being the value put on the coal lying under a little over half a mile of pipe line. The Corporation have been forced into an arbitration, and the arbitrators are at present sitting, hearing the evidence at Lancaster; should this case be successful, the town is threatened with half-a-dozen other claims of a similar character, the total amount of which would reach an enormous sum. The Corporation does not ask for this or any coal to be left for the support of their sewers, and have offered to indemnify the coal owners should any damage arise by the mines being worked; but owing to the way in which the clause applying to sewers in the Public Health Act of 1875 is framed, no provision is made for exemption, and the coal company now suing, maintain that the Corporation are bound to take the coal, although the engineer of the works, Mr. B. C. Brundell, C.E., of Doncaster, made special provision for subsidence which is

likely to arise in a mining district. A town like Wigan, therefore, is forced to dispose of its sewage by the Local Government Board, and afterwards is liable to be sued for such an amount of compensation that would lead to its bankruptcy should the claims be sustained. Sanitary authorities in mining districts are in great peril till some alteration of the law is made, for should it be decided that a company has the power to enforce payment for coal left under sewers—whether it is required or not—few would have the courage to carry out these necessary works, and the effect would be completely to stop sanitary progress.

Insurance Companies and the Working Classes.

MR. ROWBOTTOM, the coroner for the borough of Wigan, has just held an inquest on a man, set. 74, found dead in bed in a lodging house. No post-mortem was made, and the jury returned a verdict of "death from natural causes," which is something equivalent, but more materialistic, to death from the "visitation of God." In the evidence, however, it was shown he had been addicted to drinking so far back as thirteen years ago, and it was stated that the relatives had the deceased insured in some burial societies to the amount of £85. In manufacturing towns speculations in insuring lives is carried on to a frightful extent, and the insurance companies themselves are the most to blame.

The late Accidents at St. Patrick's Cathedral.

CONSIDERABLE misunderstanding seeming to prevail regarding the case of the child Francis Mooney, one of the sufferers from the falling of one of the buttresses of St. Patrick's Cathedral, we now publish the facts in connection with this case.

At about noon on Thursday last, the 14th inst., when Mr. B. Wills Richardson was about to leave the medical board-room of the Adelaide Hospital, the child Francis Mooney was brought to the hospital almost moribund from collapse with a flap wound of the scalp. The flap was triangular, raised from the frontal bone, which was exposed and cracked, the crack extending upward from apex of wound, and corresponding to its centre. The periosteum seemed thickened at base of wound as if it had been forced, as it were, at this part into a ridge; the base of the flap being intact; hæmorrhage almost nil. There was an abrasion upon the left side of frontal bone and several trifling bruises about left side of pelvis and left lower limb. Mr. Richardson immediately on the admission of the child applied himself to get it out of the collapse, placed it under the care of two of the most experienced of the hospital nurses, and had a bed made for it on the table of the board-room, where he had the satisfaction of seeing the child gradually recovering from an almost hopeless condition. The collapse lasted about an hour and quarter, during which period the pulse of the child, it may be stated, could barely be detected. Mr. Richardson did not leave the room until reaction was sufficiently established to enable him to transfer the child to the care of the resident pupil, Mr. Blandford, and the nurses. It is scarcely necessary to give the details of the surgical

treatment, but we have been informed that Mr. Richardson on the moment stated that he would at once take all responsibilities connected with the case, and that of the boy's nursemaid, whose body was so fearfully and fatally mutilated, beyond the reach of the professional aid and skill of Dr. Wallace Beatty, assistant physician to the hospital.

Ether in the Treatment of Strangulated Hernia.

DR. FINKELSTEIN, of Jassy, being called to a case of strangulated hernia that resisted all his efforts to reduce it, with a view to preparing for another attempt poured upon the tumour a mixture of ether, ol. hyoscyami, and ext. belladonnæ, when to his astonishment the swelling disappeared. Charmed with the result, he made a similar use of ether by itself, or with ol. hyoscyami, in sixty-three strangulated herniæ, with a favourable result in fifty-four cases. His method of procedure is to pour one to two tablespoonfuls of ether on the rupture every quarter-of-an-hour, after which the intestine generally recedes of itself, or is pushed back without difficulty.

The Royal Irish University.

ABOUT 450 candidates have recently been engaged in the several classes of the medical examinations of this University, which commenced on Monday, the 11th instant, and will end on Thursday, October 4th. Nearly 100 candidates were examined for the degree of Master in Surgery; 150 came up for the second examination in Medicine, and 180 for the first. There are also candidates for the diploma in Obstetrics and in Sanitary Science. Only a few on this occasion seek the degree of M.D. As on previous occasions, the examinations were held in the Exhibition Palace. In the medical section the practical testing of candidates' proficiency was carried on in the School of Physic of the University of Dublin and in a number of hospitals specially selected.

The Typhoid Outbreak at Bangor

Shows no decrease, something like 400 patients still remaining under treatment. The hospital tents in the bishop's park are being utilised for convalescents, and extra accommodation for those recovering from the fever has been secured in Upper Bangor. The outbreak has, however, extended to Bethesda, a populous quarrying district about six miles from Bangor, where it has assumed most serious proportions. Fortunately, up to the present time the rate of mortality has been low. A committee has been formed at Bethesda to organise a system of nursing and assistance for the poorer class of patients. The drainage, as well as the system of water-supply in this place, is of a very primitive character, and new works are being executed under the direction of Mr. Mansergh, C.E. No report has yet been received from Dr. Barry, who, more than a month since, was sent down by the Local Government Board to inspect the locality and furnish a report upon it.

PROF. ERB, of Leipzig, has been invited to succeed the late Prof. Friedreich at Heidelberg.

"The Northern Sanitary Association."

AN Association has been recently formed in Liverpool under the name of "The Northern Sanitary Association," having for its objects the providing "the best practical advice on sanitary matters at a moderate cost, and to advance sanitary knowledge." The association is founded and will be worked mainly on the same lines as the associations already in successful operation in Edinburgh and London. There are to be two classes of members—honorary, who pay an annual subscription of one guinea, and who must be "persons or societies interested in the development of sanitary science;" and ordinary members, who shall pay an entrance fee of one guinea and an annual subscription of one guinea. "Thus, a member occupying a house of the rent of £200, within the three miles radius (from St. George's Hall), will be entitled to a report, on payment of his entrance fee, annual subscription, and a fee of one guinea—in all, three guineas. The future annual subscriptions would entitle him to a periodical inspection free of charge, and interim inspections in cases of urgency." The names announced as already connected with the society are a sufficient guarantee of the position to which it is entitled; and when we bear in mind the very little that is known on sanitary matters—we might almost say the absolute ignorance that prevails even amongst many who live in expensive houses, and how very little leisure even the better-informed have of making themselves acquainted with the sanitary condition of their dwellings—we see what a wide scope there is for such an association, and what advantages membership will afford to occupiers of dwellings, highly rented, indeed, but in too many instances wanting in just those things that conduce to the health of its inmates. The fees to be paid on admission and as subscription may seem high, but after careful consideration they have been adopted as the lowest that could be fixed upon consistent with the efficient working of the association.

Mercer's Hospital, Dublin.

DR. CHARLES F. KNIGHT has been elected physician to this hospital, in succession to Dr. George F. Duffey, recently appointed physician to the City of Dublin Hospital. Dr. Knight is a graduate (M.D., 1877) of the (late) Queen's University, and a Demonstrator of Anatomy at the Ledwich School of Medicine. With one exception, all the members of the visiting staff at Mercer's Hospital are now connected with the Ledwich School.

Tannate of Cannabia as an Hypnotic.

DR. FROMMULLER, of Fürth, claims for tannate of cannabia that it is an excellent hypnotic; that it is at once powerful and mild; that its use is free from danger; that it does not disturb the secretions; that if the dose be properly adjusted it does not produce intoxication; and that it is well calculated to rank by the side of morphia and chloral. He administers it in doses varying from $1\frac{1}{2}$ grains to 20 grains (?)—the latter dose being given in a case of lead colic. It may be given in powder with or without sugar, or dissolved in water with the aid of a small quantity of alkali.

Parasitic Skin Diseases.

ONE of the reports to the Scientific Grants Committee of the British Medical Association, presented at the recent meeting at Worcester, contained a *résumé* by Dr. G. Thin of some of the results of his investigation upon the "Pathology of Parasitic Diseases of the Skin." With regard to the fungus of ringworm (*Trichophyton tonsurans*) he is of opinion that it is not a form of a common fungus, as has been supposed by some observers. He found that it could be cultivated artificially when moistened by vitreous humour, but when completely immersed in vitreous humour there was no evidence of its growth. This would appear to explain what takes place when, in the treatment of ringworm, recourse is had to applications which provoke inflammation, i.e., an effusion of serum around the follicles, in which the *Trichophyton* cannot develop. In ringworm of the scalp Dr. Thin says considerable caution is necessary in the choice of an application for provoking this curative inflammation; but in ringworm of the body the parasite is so well within reach that it can be easily destroyed by one application of tincture of iodine and subsequent scrubbing with soap and water. With respect to *Microsporon furfur*, the fungus of pityriasis, and *Achorion Schenleinii*, the fungus of favus, he has only obtained negative results. The destruction of the hair in *Alopecia areata* he considers to be due to minute bodies of definite and fixed shape and size, which are found in and on the hairs. They are distinct from the granular elements in hairs, and are neither oily particles nor crystals, but have the refractive properties of and are bacteria (*Bacterium decalvans*). The disappearance of the hair, resulting in baldness, is due to a breaking up of the hair shaft by the multiplication in it of these organs.

Hypodermic Application of Purgatives.

AFTER L. Lewin and Kohn had published a number of observations concerning the action of certain purgatives, if employed by the hypodermic method, A. Hillier, of Berlin, made some experiments, which he reported last month in the *Zeitschr. f. Kl. Med.* The remedy mostly recommended for this purpose is *aloïn*. Hillier observed, after injecting 0.15 to 0.2 grams of the remedy, a copious and soft discharge within four to six hours. But the action depends much upon the preparation of the remedy. *Colocynthis purum* produced, in the dose of five to ten mgrm., watery stools with slight bellyache. A solution is made with water, glycerine, and alcohol, but the injection is very painful. Just as painful are the injections made by a similar solution of *citrullin*, dose 0.005-0.01. The same can be said of *acidum catharticum* (made from senna), dose 0.2 to 0.3. We may conclude, therefore, that these injections produce too much pain, while *aloïn*, which does not cause this inconvenience, is very unreliable.

DR. COMER, Medical Officer of Health for East London, reports that the death-rate for the past three months has averaged but 16 per 1,000 of the population. He adduces figures to prove that the health of this most populous part of the metropolis will compare favourably with that of more highly-favoured districts, and hopes that it will remove the wrong impression of insalubrity commonly entertained.

Skin Eruptions in Locomotor Ataxia.

CHARCOT, Velpian, and others have observed the presence of skin eruptions (papulæ, maculæ, &c.), in cases of sclerosis of the posterior columns. These eruptions have been found to be in intimate connection with the lancinating pains of tabes. J. Strauss (*Arch. de Neurologie*), has now noted ecchymoses in the skin appearing in tabes after the paroxysmal pains. From a description in the *Centralbl. f. d. Medic. Wissensch.*, No. 16, we take the following :—

These ecchymoses show themselves only after the attacks are over, and they resemble the spots which result when the skin is pinched severely ; they have an irregular, round shape, and their size varies from that of a split pea to that of a silver half-dollar. There are usually several (3-4) spots in one extremity. They are painless, and are observed only after a very severe attack of pain, and according to the nature of the latter the spots are one- or double-sided. The spots are mostly to be found above the seat of the pain, and differ from Charcot's skin eruptions by not following the course of the nerve. Exceptionally, they appear on the extremity which is not the seat of the pain. Strauss considers these spots as rather frequent in locomotor ataxia, and brings them in direct connection with the morbid alteration of the posterior columns of the spinal cord. He thinks that they are reflex phenomena (irritation of the vaso-dilators). This seems possible, if we remember the hæmorrhages which have often been observed in cases of tabes after gastric and rectal crises (paroxysms of intense pains beginning either in the stomach or in the rectum).

Certificates of Death.

An inquest has just been held at Hallatrow, in Somerset, by Dr. Lionel A. Weatherley, respecting the death of a young girl under circumstances eminently suspicious. In the certificate of the cause of death this was given as consumption, apparently for the sake of avoiding the publicity of a coroner's inquiry. Death really arose from mercurial hæmorrhage, and it is much to be regretted that a medical practitioner should have so far forgotten his duty to the profession and society as to permit any other opinion to obtain currency through his means. All the circumstances seem to call for further extended investigation, and it is to be hoped the police will sift the matter completely, as many points brought out in evidence point to the possibility of improper proceedings on the part of those who were in contact with the deceased woman before her death.

The Army in Egypt.

ACCORDING to the statistics of the Army Medical Department, the average number of sick admitted to the Ismailia Base Hospital from August 24th to the end of the first week in September amounted to sixty-two daily, or between one-half and three-quarters per cent. of the entire British forces in the field at that date. These rates do not include the men wounded in action. Since then the army has been increased by the arrival of the Highland Brigade and other troops, and the daily average to September 13 was one hundred and forty-nine, or about one per cent. of the whole force. The majority of

the men under treatment are suffering from sunstroke and diarrhoea, while to a less extent dysentery and ophthalmia prevail. The above figures do not include the cases of sickness among the Indian troops, the number of which is, however, merely nominal.

WE understand that there is about to be a vacancy in the surgical staff of St. Vincent's Hospital, Dublin, owing to the resignation of Dr. Kehoe.

THE epidemic of scarlet fever at Accrington shows no signs of abatement, many deaths having again occurred from the disease last week.

THE examination for certificates in sanitary science of the University of Cambridge begins on Tuesday, Oct. 3. Candidates must send in their names to Professor Living, Cambridge, on or before Sept. 28th.

OWING to the epidemic of fever at Bangor, which is popularly believed to have proceeded from contaminated water, the population are now buying their supply for drinking purposes of purveyors from a distance, who import it in water-carts and tubs.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were :— Birkenhead 12 ; Cardiff, Derby, Portsmouth 15 ; Brighton, Bristol 16 ; London, Halifax 17 ; Edinburgh, Plymouth, Birmingham 18 ; Bolton, Bradford, Wolverhampton 19 ; Norwich, Sheffield 20 ; Newcastle-on-Tyne, Huddersfield 21 ; Glasgow 22 ; Nottingham 23 ; Leeds 24 ; Manchester, Dublin, Salford 25 ; Preston, Oldham, Liverpool, Leicester 26 ; Blackburn, Hull 28 ; Sunderland 38.

THE Irish probate of the will of Surgeon-Major Espine Ward, Army Medical Department, who died at Barbadoes, West Indies, granted to his brother, Mr. Montgomery Albert Ward, M.B., was sealed in London on the 16th ult., the aggregate value of the personal estate in England and Ireland exceeding £1,200. The testator's wife, who under the will took a life interest in his property, having died, all his estate becomes at once divisible between his children.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows :— Calcutta 24, Bombay 26, Madras 31 ; Paris 23 ; Geneva 16 ; Brussels 23 ; Amsterdam 20 ; Rotterdam 27 ; The Hague 23 ; Copenhagen 28 ; Stockholm 26 ; Christiania 21 ; St. Petersburg 45 ; Berlin 26 ; Hamburg 22 ; Dresden 29, Breslau 32, Munich 24, Vienna 20, Prague 21, Budapest, 31, Trieste 30, Rome 19, Naples 30, Turin 16, Venice 27, New York 34, Brooklyn 31, Philadelphia 20, and Baltimore 22.

THE Committee of the Alexander Memorial Fund has advertised a competition for a prize of £50, and a gold medal of the value of £10, for the best essay on "Antiseptic Surgery and its Application in Military Hospitals

and in the Field." The competition to be limited to executive medical officers of the army on full pay. The relative merits of the essays to be determined by assessors chosen by the Committee. The prize to be awarded to the writer of the best essay, without reference to the number of competitors, provided the writer has complied with the prescribed conditions.

THE annual death-rate from diarrhoea in the large towns last week, which had been equal to 4·6, 4·0, and 2·3 in the three preceding weeks, further declined to 2·0, when it ranged from 0·5 in Brighton and 0·6 in Huddersfield and Cardiff, to 6·6 and 8·0 in Hull and Preston. The highest annual rates from scarlet fever were 1·3 in Nottingham and Derby, and 1·8 in Sunderland; from whooping-cough, 1·3 in Huddersfield and 2·3 in Oldham; from measles, 1·9 in Huddersfield and 5·3 in Sunderland; and from fever, 1·1 in Liverpool and Newcastle-upon-Tyne and 3·9 in Sunderland. The 39 deaths from diphtheria included 23 in London, 5 in Glasgow, 3 in Dublin, and 2 in Portsmouth. Small-pox caused but 3 deaths in London, one in Leeds, one in Hull, and one in Newcastle-upon-Tyne.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE NOTIFICATION OF INFECTIOUS DISEASES.—The Town Council of Edinburgh received on Thursday last a deputation from the Corporation of Liverpool anxious to gain information as to the working of the Edinburgh Municipal Police Act relating to the notification of infectious diseases in the city. Some interesting facts not generally known may be of use to those who are now pressing for an application of the provisions of the Edinburgh Act to their own towns. In the first place the medical practitioners were against the provisions placing the *onus* of reporting infectious diseases upon them; and their opposition was only withdrawn on the distinct undertaking that they should be relieved from that duty. The passing of the Act in its present form was, therefore, contrary to their wishes; and if they have apparently acquiesced, motives of policy rather than a belief in the value of the present system is the more than probable cause of their silence. Besides, it is no easy matter to extract a candid statement on the subject in small places, where the expression of opinion might entail pecuniary loss; and men in this generation are beginning to look upon the martyr's crown as more fitting for the head of a fool than for that of a wise man. It is also open to question whether infectious diseases are less prevalent in Edinburgh than they were before the passing of the Act. In August—considered the healthiest month in the year—there were no less than 227 cases of infectious disease recorded, of which 153 were scarlet fever, and of these 65 were in the New Town, which during the month mentioned is nearly depopulated. This gives 16 new cases of scarlet fever every week, and witnesses to the exceeding value of the reporting system adopted in Edinburgh. The weakness of the whole system is the want of proper and immediate isolation of the sick, without which the mere reporting of the cases as they occur is a mere farce. The reporting forms permit the medical attendant to decide as

to whether the case demands "immediate attention"—that is, removal to the hospital or not. Now, men who will not run the risk of martyrdom for the expression of their opinions are not likely to send a case to hospital, and lose three or four weeks' attendance on it. Yet every case, without immediate and perfect isolation, whether rich or poor, is a focus of infection. The wonderful advantages derived from the simple notification of infectious disease exist more in the fervid imaginations of its advocates than in any real good to the people.

FEVER HOSPITAL ACCOMMODATION IN EDINBURGH.—An arrangement seems likely to be come to immediately between the municipal authorities and the managers of the Royal Infirmary regarding the question of accommodation for fever patients in the city. The managers of the new Infirmary, it will be remembered, undertook to provide that not fewer than 74 beds should be so set apart in the old Infirmary for fever patients, and those suffering from febrile disease. This arrangement was given effect to, and a portion of the old Infirmary fitted up as a fever hospital, at a cost of between £2,000 and £3,000. The cost of maintenance, however, involving as it does a separate staff, has been found so considerable, that the managers some time ago brought the matter under the consideration of the Town Council. They suggested that the municipal authorities should take advantage of the provisions of the Public Health Act, which empowers the Local Authority to provide for the treatment of such cases, the cost being defrayed out of the rates, and that in this way a payment should be made by the city to the Infirmary of at least a portion of the expense connected with the maintenance of a separate fever hospital. The matter has been under the consideration of a joint committee of the Lord Provost's, the Public Health, and the Law Committees for some time. As the result of their deliberations, it is thought that the best and most economical arrangement, both for the Infirmary and the city, would be to make an annual payment out of the rates to the Royal Infirmary, on the understanding that they continue to treat all fever cases in the old building, and that only in cases of epidemic should there fall a charge on the city rates over and above this annual grant. It is proposed that the grant should not exceed £2,000—a sum with which it is understood the Infirmary managers will, in the circumstances, be well satisfied.

HEALTH OF EDINBURGH.—At a meeting of the Public Health Committee, held last week, Dr. Littlejohn submitted his usual report on the health of the city. The total number of deaths during August was 326, giving a death-rate of 16·89 per 1,000 of the estimated population. The average death-rate for the five preceding years in the corresponding month was 16·75. Of the total deaths, 84 occurred in the New Town, 216 in the Old Town, and 26 in the southern suburbs. As regards age, 118 of the deaths were registered as under five years of age, 151 between five and six years, and 57 above six years. Deaths from diseases of the chest amounted to 101, while 80 were due to debility and old age. Diseases of a zymotic nature proved fatal in 18 cases. During the month 590 births were registered, giving a rate of 30·58 per cent. per annum of the population, 39 being illegitimate. There were 227 cases of infectious disease reported, comprising 153 cases of scarlatina, 41 of measles, 20 of typhoid fever, 11 of diphtheria, and 2 of typhus. Of the scarlatina cases, 65 were in the New Town, 73 in the Old Town, and 15 in the southern suburbs. Of the typhoid fever cases, 9 were in the New Town, 8 in the Old Town, and 3 in the southern suburbs.

GLASGOW DEATH-RATE.—For the week ending with Saturday, the 16th inst., the death-rate in Glasgow was 23 per 1,000 per annum, being the same as the previous week. For the corresponding periods in 1881, 1880, and 1879, the rates were 21, 24, and 19 respectively.

ABERDEEN.—THE THREATENED TYPHUS EPIDEMIC.—Dr. Simpson, the medical officer of health for Aberdeen, has prepared and submitted to the Town Council of Aberdeen a report on the sanitary state of the city, in which he states that the returns for the month of August gives the deaths in Aberdeen at 173, equal to an annual rate of 19.39 per 1,000. Typhus fever, the officer reports, which a short time since threatened to become epidemic in Aberdeen, has now been stamped out. Dr. Simpson complains of overcrowding and bad ventilation in Aberdeen as conducive to the spread of such an epidemic as that from which the city has escaped, and he suggests the clearing out of a number of the courts in the poorer districts of the city as the only means of accomplishing a better sanitary condition.

ANDERSON'S COLLEGE.—WESTWARD REMOVAL OF THE MEDICAL STAFF.—For some time past the medical staff particularly of this school have been desirous of a western migration, to be in more direct competition with the University. At a meeting of the trustees, held on the 22nd inst., Dr. J. B. Russell called attention to the proposed removal of the Medical Faculty of the College westwards, and asked that the trustees in their corporate capacity would assist them in making an appeal to the public in furtherance of their views to a greater extent than they had been doing. Mr. M'Kinlay urged the removal of the whole institution. He pointed out that the number of scholars attending certain classes was considerably less than it was ten years ago, not from any fault of the professors, but from their altered circumstances. He maintained that the cost of the removal of the Medical Faculty would be some £14,000, while the removal of the whole would be less than £30,000, against which they had to place the value of their present site. Its removal westward near to the Western Infirmary would place it in the centre of a population of two hundred and fifty thousand. The chairman said the matter of the removal had been for some time under consideration of the managers, by whom a report would be issued in due course.

Literature.

THE DISEASES OF THE SPINAL CORD. (a)

THIS clear, comprehensive, and profusely illustrated work is composed of a part of the course of lectures on medicine which is delivered by Dr. Byrom Bramwell in the Edinburgh Extra-Academical School. In that course it is Dr. Bramwell's practice to teach by the eye as well as by the ear, making copious use of diagrams, drawings, and microscopical preparations, and in that portion of the course which is now reproduced the same practice is faithfully and happily followed, exactly one illustration being supplied for two pages of print. The illustrations being derived from various sources, including the publications of Charcot, Ferrier, Flower, and Gowers, as well as Dr. Bramwell's own pencil, are of very unequal merit; some being elaborate and highly finished, and others crude and ill executed; but, whatever their artistic excellence or defects may be, they are of extreme value in elucidating and simplifying the text, and in impressing its lessons on the memory. None of them can be said to be superfluous, and some of them are essential to the explanation of the complexities which modern physio-

logical and pathological research have revealed in relation to the structure and functional activity of the spinal cord in health and disease. No one who is not a professed neurologist could, without the aids to the eye which are provided in this volume, follow even Dr. Bramwell's plain and perspicuous descriptions, or carry away many practical lessons; but with the engravings and chromo-lithographs which stud its pages, the treatise becomes intelligible and instructive to all who will be at the pains to read it attentively. It will, therefore, be of service to that body of medical practitioners—an ever increasing body in this country—who desire to keep abreast of medical science as well as to the student for whose use it is perhaps more especially designed, and we are much mistaken if certain of the drawings which it contains do not pass into the mental portfolios, if we may so say, of many members of the medical profession, to be often referred to by the sick-bed or in the consulting-room, for the interpretation of obscure symptoms.

Dr. Bramwell's work does not, of course, occupy new ground, nor can it be said that it is as much wanted as it would have been two years ago, before the publication of Gowers' careful monograph on Diseases of the Spinal Cord; of Ross's eminently philosophical treatise on Diseases of the Nervous System, in which spinal affections are so exhaustively dealt with; of the seventh edition of Aitken's Science and Practice of Medicine, in which the same subject is so ably and learnedly treated; of Althaus on Diseases of the Nervous System, and of other kindred works. And yet, notwithstanding all that has been written on Dr. Bramwell's theme, there is still room for his new disquisition on it, which, while reproducing much that has been already set forth in the works named, has some features that are peculiarly its own. It enters more fully and systematically than other text-books into the morbid histology of the spinal cord, and affords directions of singular minuteness and precision for clinical examination in cases of spinal disease. Nothing is left to be desired in its treatment of the pathological anatomy of intra-medullary lesions, as regards both primary morbid processes and secondary degenerations, and in its method of case-taking and summary of symptoms.

The scheme of diagnosis which Dr. Bramwell offers is not, in our judgment, equal to that of Dr. Gowers. No doubt everything that is essential to diagnosis is included in the chapter on the subject, but the plan adopted does not seem to guide the investigator as precisely and directly as does that of Dr. Gowers, through doubts and difficulties to the only justifiable conclusion. We miss also in Dr. Bramwell's work the scientific breadth that is so conspicuous and admirable in the pages of Dr. Ross, and if we were disposed to find fault with him we should accuse him of exalting the spinal segment at the expense of the spinal cord. A novice, dipping into his book might be inclined to question whether man had yet emerged from amongst the articulata, and might regard him as a mere string of spinal beads, each with a pair of nerves and some bodily appendance attached. No doubt, the separate and systematic examination of each spinal segment, by the observations of the motor sensory, reflex, vaso-motor, and trophic conditions of its body area, is of the first importance in the study of diseases of the cord, but the attention bestowed upon distinct units must not withdraw notice from the grouping of functionally related segments, and from the unifying and co-ordinating influences of the great physiological tracts of the cord, of the blood-supply, and of the domination of the cerebrum to a greater or less degree over each and every segment. The exact localisation of experimentally induced phenomena is of much less importance to the practitioner than the correct appreciation of clusters and processions of symptoms as they occur in disease. The condition of other parts of the nervous system beyond that primarily involved in cord lesions has not yet been sufficiently investigated. When more complete inquiries have been carried out in this department of neurology it will probably be found that deviations from mental health are not so uncommon as is generally believed in spinal diseases. The delirium which sometimes occurs during polio-myelitis, anterior acute, and spinal meningitis, and the hallucinations and progressive fatuity of sclerosis have been noted, but beyond this there is scarcely any record of psychological symptoms in spinal diseases in books treating specially on the latter. In the literature of insanity, however, there are more frequent references to the association of mental affections with changes in the

(a) "The Diseases of the Spinal Cord." By Byrom Bramwell, M.D., F.R.C.P. Ed. n. Edinburgh: MacLachlan and Stewart. 1882. Crown 8vo. Pp. 300.

cord. Thus, it has been alleged that certain well-marked varieties of mental aberration have been noticed during the progress of locomotor ataxia, with reference to which allegation Dr. Bramwell only remarks that the symptoms of locomotor ataxia are not unfrequently developed in the course of general paralysis of the insane. But the converse of this statement would be equally true, for numerous reported cases make it evident that some of the symptoms of general paralysis of the insane are not unfrequently developed in the course of locomotor ataxia.

In common with most other recent works on diseases of the spinal cord Dr. Bramwell's is less full and explicit than could be wished in the topic of treatment, which is, after all, the paramount consideration. Under the different diseases all useful remedies are enumerated, but in some instances the indications determining the choice of remedies, and the periods for their employment are not perhaps adequately set forth. This defect is, however, likely to be removed in future editions, all the more so because the progress of research will, it is to be hoped, put in our hands more efficient remedies than we now possess.

So excellent as a whole is Dr. Bramwell's work that it is almost impossible to criticise it without appearing to be captious. It is entitled to a cordial reception as a lucid, concise, and thoughtful text-book of diseases of the spinal cord.

SPASMODIC ASTHMA. (a)

WITHIN the narrow limits of a university thesis the author tells us much that is curious and interesting connected with the mysterious and troublesome disease to which he has himself during his life been more or less a martyr. It has been said that nobody really understands sickness unless he who has himself been sick, and we have got from Dr. Steavenson's monograph a number of *practical* hints and "tips" about the treatment, relief, and prevention of asthma. He does not add much that is new about remedies; but gives a great deal that is valuable about the mode of using them. He is a firm believer in the good or evil effect upon the convalescent of certain airs and localities, and this we know to be correct.

ECZEMA AND ITS MANAGEMENT. (b)

It has been well remarked that a knowledge of eczema is the entrance to the science of dermatology, and we have read this valuable treatise with pleasure and profit. As the well-known translator of Neumann's work on skin diseases the author has already written extensively and ably in America on the subject of eczema; and the present volume appears to be a combination of all his previous labours, together with much new matter. Dr. Bulkley is, we are glad to see, a firm believer in the constitutional origin of eczema, and of the necessity of combatting it by constitutional as well as by many local treatments. His work is a valuable contribution to medical literature, and a specimen of the advances which our American cousins are making in this direction.

THE PHYSIOLOGY AND PATHOLOGY OF THE BLOOD. (c)

THE peculiarity of this work is that it attacks almost every accepted fact concerning the constitution and development of the blood. The author admits that the blood is a fluid in which corpuscles float, certain of these being flat, coloured, circular discs, whilst others are spherical, colourless corpuscles. Beyond this point he is altogether at variance with his contemporaries. But whilst his destructive tendency is great, his constructive power is equally so,

and the result is that a totally new theory of the constitution and development of the blood is evolved. In addition to the coloured and colourless corpuscles, he describes a third series of corpuscles, which are in great part invisible, and to which he gives the name of the "fugitive group." In form they are flat, circular, biconcave discs, and they are invisible, owing to their having precisely the same refractive index as the liquor sanguinis in which they float. Between the altogether invisible disc and the ordinary red corpuscle he believes that there is every gradation; that the former gradually, by the acquisition of the colouring matter, hæmoglobin, and by alterations in its chemical constitution, becomes the latter.

With regard to the white or colourless spherical corpuscle, he draws a distinction between those which have a single nucleus and those which have two, three, four, or, it may be, five nuclei.

His views regarding the structure of the corpuscles are somewhat startling. He combats the theory that the red corpuscle is a solid body consisting of a delicate reticular stroma infiltrated with hæmoglobin. Hewson's idea that small quantities of liquid swimming in a large quantity of fluid in which they are not soluble, become globular, he considers to be altogether erroneous, and he holds that the blood disc is a liquid body, and "that its biconcave shape is due to the operation of physical conditions, and not to structural restraint." He adduces a number of elaborate and ingenious experiments to prove this. We fear, however, that he will have some difficulty in obtaining general acceptance of his theory.

The ordinary white corpuscle is clothed with a cell-wall. This he claims to demonstrate by certain reagents which, by causing a "species of imbibition or osmose," renders the cell envelope apparent. Even his excellent micro-photographs are insufficient to convince us of this addition to the constitution of a white corpuscle. Further, he is bold enough to deny the presence of Hitzmann's intra-cellular network.

His conceptions of the origin and development of the blood corpuscles are so clear and simple, and the links of his chain are so complete, that it indeed would afford physiologists a great satisfaction—not to say relief—should they prove to be correct. We cannot, however, conscientiously state that he has made his position unassailable; all we can say is that he suggests a consistent theory, and supports it with great ability and great ingenuity.

Very properly he dissents from the growing tendency there is for physiologists to insist upon the identity of the lymph and splenic corpuscle with the white blood corpuscle. The lymph and splenic corpuscles are usually smaller, and uni-nuclear; the white corpuscle, whilst it may be uni-nuclear, is more frequently multi-nuclear. We are rather sceptical as to Dr. Norris's statement that the lymph corpuscles are disc-shaped, although they certainly present that appearance in his photographs; and we still further question the presence of a cell-wall in these corpuscles. In addition to the ordinary lymph corpuscles found in the spleen and lymphatic glands, he describes smooth, flat, non-nucleated discs which are very plastic and difficult to demonstrate. To these he gives the name of *advanced lymph corpuscles*, whilst he terms the ordinary lymph corpuscles the *primary lymph corpuscles*. He believes that the *primary corpuscle* gives rise to the *advanced corpuscle* by the loss of its cell-wall and the special development of the nucleus. The advanced corpuscles entering the blood, become members of the fugitive group, which in turn are converted into the red corpuscles. This he styles the *major mode* of red-corpuscle development, and the stages are the following:—(1) Primary lymph, splenic or thymic corpuscle; (2) advanced lymph, &c., corpuscle; (3) fugitive group of corpuscles in the blood; (4) the fully-developed red corpuscle.

But Dr. Norris also endeavours to explain the origin of the white blood corpuscle. "If," he states "the primary lymph cell fails to undergo *enucleation*, it passes on into the blood, and becomes there the uni-nuclear white corpuscle, from which, by proliferation of the nucleus, the multi-nuclear varieties of this body spring." The existence of the multi-nucleated white corpuscle is brought to a close by the discharge of its nuclei, which flatten, become biconcave, and join the fugitive group of blood-discs. This Dr. Norris terms the *minor* or indirect mode, or *red-corpuscle* development.

(a) "Spasmodic Asthma." A Thesis for the M.B. Degree of the University of Cambridge. By W. E. Steavenson, M.B., M.E.C.S. Cambridge: Deighton, Bell, & Co. Second Edition. Medium 8vo. Pp. 31.

(b) "Eczema and its Management. A Practical Treatise based upon the Study of 2,500 cases." By L. Duncan Bulkley, A.M., M.D. London: J. & A. Churchill. Royal 8vo. Pp. 38.

(c) "The Physiology and Pathology of the Blood." By Richard Norris, M.D., F.R.S.E., Professor of Physiology, Queen's College, Birmingham. London: Smith, Elder & Co. 1892.

Such is a very brief epitome of the leading views advanced by Dr. Norris in his interesting and highly-suggestive work. It would be impossible to criticise them with any degree of fairness without re-treading step by step the same ground. This, to some extent, has been already done by a reviewer in the *London Medical Record* (January, 1880); and not the least interesting part of Dr. Norris's book is the section which he devotes to answering the criticisms which were then advanced.

It is a suspicious feature in a book evolving a new theory when the author tilts without fear or favour at every accepted view. It is to be regretted that the spirit of Dr. Norris's book is so much of this kind.

One great advantage to be gained from Dr. Norris's work is to show the success with which micro-photography can be applied to investigations of this kind. We quite agree with the author when he states that "many delicate things can be observed in photographs which, owing to the sameness of tint and the glare of light in the microscope, can only be seen with difficulty, and in some cases not at all, in the original specimens." The micro-photographs which accompany the text of Dr. Norris's book are exceedingly beautiful.

Obituary.

JOHN ALEXANDER SPENCER, F.R.C.S.I.

We regret to have to announce the death of Dr. John Alexander Spencer, which took place at his residence, Burton Port, co. Donegal. Dr. Spencer was a licentiate of the King and Queen's College of Physicians, and a Fellow of the Royal College of Surgeons in Ireland. Dr. Spencer was surgeon in the United States army during the American war, and afterwards succeeded the late Dr. Handsell Griffiths as assistant-librarian to the Royal College of Surgeons in Ireland, which position he resigned some twelve months since, and was elected medical officer of the Dungloe Dispensary, Glenties Union, and Admiralty surgeon for the district.

THE SOCIAL SCIENCE CONGRESS.

THE meeting of the Congress which has just terminated has not been one of its most successful, although the civic authorities of the town had munificently voted the whole expense incident to the meeting, and the University Buildings, where the meetings were held, fulfilled every possible requirement. The number of members who attended was not quite up to average, nor were the addresses of sectional presidents as bright and interesting as might have been desired. Nevertheless, much good work was got through, and the meeting, if not an especially brilliant one, may be classed as one of the successful efforts of the Association. The Public Health Section was chiefly employed in debating three questions: 1. The influence of female factory work on infant mortality; 2. The reform of hospital management; and 3. The notification of infectious disease.

The factory question was opened by a valuable paper by Dr. T. M. Dolan, of Halifax, who advocated the abstention of female factory operatives from work for a fortnight before lying-in and a month afterwards. A paper by Dr. R. Martin also declared the necessity for some legislation to limit the employment of women at such time; whilst a communication by Mr. Cooke Taylor combated the proposals, and advocated perfect freedom of action in the matter. The debate on this subject made it manifest that not only was some arrangement necessary to provide rest for the operative before and after parturition, but such system was working effectively on the Continent.

The reform of hospital administration gave rise to an interesting debate in connection with the proposal that a central board of superintendence should be appointed to supervise that

administration. A resolution in favour of such appointment was eventually passed.

The Notification of Infectious Disease was the subject of an entire day's discussion of the warmest character. The subject was introduced by two papers, by Mr. Michael, Q.C., and Dr. Littlejohn, both of whom have always been enthusiastic compulsionists. We understand that a paper was offered on behalf of Dr. Carter, of Liverpool, which would have taken the opposite view, but that it was declined by the Council of the Association for some unknown reason, the effect of which decision was, in great measure, to prejudice the question in favour of the compulsionists. The cause of the profession was maintained by Dr. Brookhouse, of Nottingham, Dr. Whittle, of Liverpool, Dr. Jacob, of Dublin, and other physicians, while the onslaught was delivered by a posse of medical officers of health, including Dr. Hill, of Birmingham, Dr. Leaton, of Nottingham, and Dr. Cameron, of Dublin. Mrs. Sherers spoke also as the representative of the Vigilance Committee for Defence of Personal Rights against compulsion.

At the wind-up of the debate, Mr. Powell, M.P., proposed an unexpected resolution, pledging the meeting to approval of Mr. Hastings' Bill, and his proposal was seconded by Mr. Collins, and this motion, on being put from the chair, was met by Dr. Jacob by an amendment of "the previous question." After a good deal of turmoil, the Chairman delivered himself of the strange ruling that no amendment could be entertained, and that the question must be decided by a vote upon Mr. Powell's resolution. Against this ruling many members strongly protested, as being both unconstitutional and contrary to the usage of the Association, and, on a poll, the greater number of the members present abstained from voting altogether, and the division resulted in a majority of 38 to 16 in favour of the motion.

A vote thus arrived at could not, of course, influence the question in the least, for it is manifestly an improper course to seek without previous notice to pledge a meeting to approval of a Bill which was not before them and with which most of the members were totally unacquainted, and it is equally improper to suppress discussion of every alternative offered. We, therefore, cannot congratulate the compulsionists on a victory, nor, indeed, upon the line adopted by their advocate, Mr. Michael, Q.C., whose style was truculent and language offensive. This gentleman is evidently unable to debate public questions with good temper and polite language, and it would be as well for the compulsionists to select a more conciliatory representative in future.

WE regret to learn by telegram that the serious attack of cardiac dropsey by which our valued Indian correspondent, Surgeon-Major Hogg, had been seized, has ended fatally, at Morar, whither he was stationed with his regiment. Deceased was in the prime of life—46 years of age.

SIR JAMES ALDERSON, M.D., F.R.S., who died a few days since at the ripe age of 87, was, we believe, with one exception, the oldest Fellow of the Royal College of Physicians of London, of which he was three years President.

Correspondence.

AMPUTATION OF THE SCROTUM FOR ELEPHANTIASIS ARABUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 6th inst., you published an article upon the above subject, by Dr. G. V. MacDonogh, which contains various references to myself, and to my paper on the above subject, published in the June number of the *Glasgow Medical Journal*.

I would not deem it worth while to trouble you with any

communication in reply were it not for the following remark made by Dr. MacDonogh in writing about one of the errors which crept into my paper, errors which have already been publicly corrected by me in the July number of the *Glasgow Medical Journal*, a copy of a reprint of which corrections I sent to Dr. MacDonogh.

Dr. MacDonogh says: "But perhaps this inaccuracy may be accounted for by another of his statements in his letter to me of the 22nd June, 1882, in which he says, 'I found that your name had dropped out of the Medical Directory, and I reluctantly came to the conclusion that you were dead.'"

What is meant to be gathered from that quotation is plain, and in justice to myself I must ask you to allow me to continue Dr. MacDonogh's quotation from my letter to him of 22nd June last. The words immediately succeeding those above quoted are as follow:—"Afterwards it occurred to me that I might find out about you from Dr. S—, and so I wrote him last March, asking about you. He replied that you 'applied for and were granted twelve months' leave of absence from England in July last.' His reply was dated 25th March, and it was of course impossible for me to communicate with you anywhere abroad, after that, before reading my paper on 7th April, as I had promised."

In a subsequent letter from Dr. MacDonogh to me, dated 1st July, 1882, he says: "I cannot but think that you considered me dead when you wrote your paper as you informed me in your letter, and when you heard from S— that I was living on the Continent you perhaps said to yourself, he will never see it." In replying to that on 4th July, I said: "I must protest also against your statement commencing 'I cannot but think that you considered me dead,' &c. I have already informed you that when I was writing my paper I found out through Dr. S— that you were still alive, and would be home in July, and when I read and published my paper, I knew that you would read every word that I had written regarding you. So far from 'striving to asperse your memory,' I had distinctly stated in my paper that it was what I learned from your cases that 'gave me confidence to undertake similar cases afterwards, and laid the foundation for the subsequent success with which I met in the treatment of them.'"

Notwithstanding these repeated statements on my part, Dr. MacDonogh again virtually charges me in your columns with deliberately publishing what was untrue on the faith that he was dead and would never be able to correct it!

Yours faithfully,

GEO. A. TURNER, M.D.

Glasgow, 22nd Sept., 1882.

Notices to Correspondents.

MR. ANGUS.—We are much flattered, and especially since you only reflect the opinions of numerous other correspondents on your side the Tweed. We are glad to use our influence for good, and always wish to receive suggestions that may help the accomplishment of this desire. Your wish has been acceded to.

R. T. G.—It could not be used in consequence of the whole of our space having been devoted to special intelligence respecting the hospitals and examining bodies. Any further information of a similar nature will be acceptable, and will of course be employed at the right time.

ENTHUSIAST.—You could not easily perform the operation on yourself, and if you got another to perform it he might be open to prosecution for vivisection without licence. The Society which is so careful of the few animals which suffer under the hands of scientific investigators, while it regards unheeding a millionfold greater cruelties daily occurring, is not dead, but stunned. The blows under which it is suffering are such that we believe the "officers" have very little hope of ever again being able to exercise the same amount of influence as formerly. If you go to Paris you will find many both able and willing to assist you.

DR. J. B. (Liverpool).—The notice has not been received; if it comes to hand we will prevent its insertion and communicate.

DR. KINLOCH PATTERSON (Perth).—We will look through the paper, and if suitable will give it early insertion.

MR. G. P. F.—You will find the object of your inquiry answered in our issue for August 9th.

DR. BIGAUD (Paris).—Full information upon the various colleges and schools of the United Kingdom will be found in our "Students' Number" for Sept. 20th.

SURGEON-GENERAL C. R. F.—The "Clinical Cases with Remarks" referred to in your note would be acceptable.

MR. HAGERSTON (Newcastle).—Sorry we cannot put your library

on our free list; the number sent was in accordance with our annual custom of presenting all the libraries in the United Kingdom with the "Students' Number."

THE CHINESE MATERIA MEDICA.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Why Mr. Frederick Newcome, F.R.S., should favour the medical profession with his somewhat lengthy lucubration on the *Materia Medica* of the Celestials is, to me, an enigma, and doubts will remain so to many of your readers, for all must acknowledge that a great number of drugs already utilised in this country are, to a certain extent, superfluous, and too numerous, without having useless additions made; and besides, I think we need not go to the land of Confucius to seek for new remedies when we have so many at hand.

The ingenious writer argues that the sole reason for the alleged longevity of the "Heathen Chinese" is due to the wonderful properties of his almost incalculable number of remedial (?) agents, and that they also protect his prolific race from "cholera, famine, yellow fever," &c., and even shield them from the pernicious effects of the insalubrious condition of their dwellings. Reading this, "I am inclined to join the good Dominie in crying 'Prodigious!'"

I am sure all must thank him for his praiseworthy and laborious undertaking, and particularly so when he draws our attention to a certain marvellous pill, which, "according to M. Huc and later travellers," consists of a little piece of paper on which the medical Lama scribbles the name of the "specific medicine," and which "the confiding patient" swallows, and, let us hope, to his entire satisfaction.

Mr. Frederick Newcome is not so very complimentary as regards the questionable talents of the "childlike and bland Chinese" as he is respecting his *materia medica*, for he informs us that "Europe has discovered its match in double-dealing, adulteration, cheating, and similar recondite sciences;" consequently, we may justly infer that the "doctors" who prescribe their invaluable nostrums to cure "Ah Sing" of his maladies not unfrequently receive aid for their professional services. I think your numerous readers will join with me in saying, *Cui bono?*

Yours, &c.,

Birmingham, September, 1882.

F.R.C.S., F.R.S.

MR. ENSLEY (Kensington) will find his questions answered on reference to our last number.

Vacancies.

Charing Cross Hospital Medical School.—Demonstrator of Practical Physiology. Applications to be addressed to the Dean, 62 Chandos Street, W.C., on or before Oct. 2nd.

Dursley Union.—Medical Officer. Salary, £80, with fees extra. Applications to be addressed to the Clerk to the Guardians not later than Sept. 27th.

Granard Union, Fines Dispensary District.—Medical Officer. Salary, £100, and £14 as Medical Officer of Health Election, Oct. 14th.

Lismore Union.—Medical Officer. Salary, £100. Election, Oct. 4th.

Northampton General Infirmary.—Physician. Applications to be addressed to the Secretary not later than Oct. 27th.

Western General Dispensary, Marylebone Road, N.W.—Resident House Surgeon. Salary, £100, with apartments, &c. Applications to be forwarded to the Secretary on or before Oct. 2nd.

Births.

LEFTWICH.—Sept. 20, at 241 New Cross Road, S.E., the wife of C. H. Leftwich, M.R.C.S., of a son.

MANSON.—Sept. 18, at Alford, Aberdeenshire, the wife of Patrick Manson, M.D., of a son.

Marriages.

LOGIE—ABEL.—Sept. 21, at the parish church, Kinsell, N.B. J. C. Logie, M.D., of Morpeth, to Emily, daughter of the late Rev. J. C. Abel, of Forgue, N.B.

M'ARDLE—KING.—Sept. 18, at Rathgar, John S. M'Arde, of Dublin, to Miss Madeleine King.

MEYERS—WOODLEY.—Sept. 21, at Lewis Lane Parish Church, Herbert H. Meyers, M.R.C.S., of Battersea, to Jessie, daughter of John Woodley, of Forest Hill.

PHILLIPS—ANDERSON.—Sept. 21, at St. Bartholomew's, Sydenham, W. A. Phillips, M.D., M.R.C.P. Lond., to Isabella, daughter of W. C. Anderson, Esq., of Sydenham.

Deaths.

ALDERSON.—Sept. 18, at his residence, Berkeley Square, London, Sir James Alderson, M.A., M.D., F.R.S., Physician Extraordinary to the Queen, aged 87.

BIRD.—Sept. 21, at Heaton Chapel, near Stockport, J. Durham Bird, M.B., aged 44.

BELL.—Sept. 20, at 8 Baby Place, Bath, Henry Bell, M.D., aged 55.

DAVIS.—Sept. 21, at Bournemouth, Jane, wife of J. Hall Davis, M.D., of London.

HARRIS.—Sept. 16, at The Avenue, Blackheath, Surgeon-Major Wesley Poulett Harris, M.D., aged 61.

HOGG.—Sept. 21 (by Telegraph), at Morar, India, Surgeon-Major Francis R. Hogg, M.D., aged 44, eldest son of the late Dr. John Hogg, of Truro.

LEWIS.—Sept. 8, at Whitby, Waller Lewis, M.D., Chief Medical Officer of Her Majesty's Post Office, London.

PALMER.—Sept. 14, Thomas Spinner Palmer, M.D., of 32 Merrion Square North, Dublin.

THOMPSON.—Sept. 21, killed accidentally, Dr. Thompson, of Lismore, co. Antrim.

WALLACE.—Sept. 3, at 15 Russell Place, Dublin, James Wallace, M.D., aged 72 years.

HYSTERICAL SPINE.

By OSMAN VINCENT, F.R.C.S. Ed., M.R.C.S. Eng.
Surgeon to the National Hospital for the Deformed.

I HAVE ventured to bring the following cases under the notice of the readers of the *Medical Press*, in the hope that they may prove not only of interest, but the means of assisting the diagnosis of a class of cases at present too little understood, and therefore either magnified to a degree to which they are not entitled, or treated with less attention and consideration than they deserve. The subject of hysteria is a very ample one, and I shall not attempt to touch upon the general pathology, and the different phenomena of this most curious disease, but shall content myself with describing the symptoms and treatment of the particular form of hysteria known as hysterical spine.

The first symptom and the usual reason for the first visit of the patient is pain. "I have such awful pains in my back." Now in slight, and even in severe, cases of lateral curvature, which particular deformity the hysterical spine most nearly simulates, there is seldom any pain, and when we come to investigate this pain we soon discover its nature.

We are all aware that, when any of the tissues of the body are the seat of acute or chronic inflammation, the pain which results is augmented by pressure; but the pain we are considering, and which is alleged by the patient to be "all down the spine," is not increased by pressure. For instance, if the patient is placed face upwards on a firm mattress or couch, the whole weight of the surgeon's body transmitted to the spine by means of the open hand will give no pain; but, on the contrary, if the finger be drawn lightly over the spinous processes, from the cervical portion down to the sacrum we shall hear a scream or sob, together with considerable cringing or flinching. So the apparent suffering of the patient bears no proper proportion to the pressure exercised.

Another test producing a very characteristic symptom of these cases is to tap gently the spinous processes as the patient stands erect before you. The same flinching will be observed, and by these means one is often enabled to more or less localise the pain. The seat of this will generally be found in the lumbar region, especially if we can trace any uterine irregularity arising from any cause whatever. The second symptom is deformity. This may exist in various degrees, from being hardly noticeable to an extent simulating the worst form of lateral curvature; but, unlike that far more serious disease, the hysterical deformity can in a minute be reduced, although, when the pressure or manipulation necessary for this is removed the deformity returns; yet for the moment it has vanished, and we have satisfied ourselves that there is no structural change.

These two symptoms will generally be found sufficient to determine the nature of the case, especially if our diagnosis be assisted by the existence of any of those morbid conditions of the emotional centres so well known and recognised in the phenomena of hysteria.

The prognosis of hysterical spine is generally favourable, especially in the younger cases. I have never seen a case under thirty that has not completely recovered, and I am of opinion that such of the older cases which do not get well, are due to climacteric disease, and are better dealt with by the obstetrician than by the surgeon.

In the treatment of these cases, if there is anything like severe apparent deformity, nothing short of an instrument will do; but this should be of the lightest and simplest kind, for we do not want to exercise any force to overcome adverse muscular or fibrous contraction, but simply to support the spinal column, and supply the place, *pro tem*, of those muscles, which have, as it were, "struck work," and remind them of their use and duty.

Our next valuable agent to the support, and in slight cases to be used without it, is cold water. There is generally an innate dislike in hysterical patients to this most valuable remedial power, but of all treatment this is the most reliable, acting, as it does both on the superficial nerves, and also on the whole system, by means of shock. The best way of applying the cold water is, if possible,

by the douche, with as much force as the patient can bear; but if this is not available—and in very few private houses can it be efficiently carried out—then a large sponge and hip or sponge bath are all that is needful, the sponge being filled with cold water, and held at the nape of the patient's neck, and slowly, *very* slowly squeezed, the water thereby being allowed to *trickle* down the spine.

This, followed by a sharp friction with a glove of some soft texture at first (as hysterical patients cannot bear the coarser forms, such as horsehair, or Cash's towels, for the first few weeks) tends very greatly to help the cure. This douching should be morning and night, care being taken that a good reaction sets in after each application. Two or three hours rest should follow on the rubbing. (This rubbing should be on a hard mattress, and without the support, if one be worn). Then five minutes trapeze-work, the trapeze being just high enough for the patient to swing clear of the ground. After this more repose, and afterwards a good walk of a mile or two out and home (according to the strength of the patient), without loitering or looking into shop windows. This *régime*, if regularly carried out, will be found all that is necessary in the way of external remedies.

As regards internal remedies, they are not of much use, except as influencing the mental state of the patient; but as a rule, the more disagreeable and nastier the mixture is the better, as it is a sort of inducement to the patient to exert herself in order to get better, in order to be able to leave off the obnoxious medicines. I usually give a mixture of strychnine, valerian and sulphate of magnesia, and find that is about as nasty as it is possible to get.

Above all, good moral influence is the thing for these cases. Never, for your own credit's sake, treat a case at her own home, where there is at least one sympathising relative, who, by his or her weak and injudicious pity and interference, defeats your best attempts at cure. Get the patient away from all friends, and place her with some gentle but firm woman who will carry out your orders with a conscientious, but kind, strictness, and who, while paying little heed to the hysterical cry, will at once relax any of the treatment that may, in the individual case, seem too severe.

By these simple means, if properly carried out, you will, in a few months, or even weeks, return to her delighted friends, cured, the case that has probably come to you as one of severe spinal disease with structural change, and surrounded by alarming complications.

CASE I.—H. A., 24, a well-developed, florid-complexioned girl, presented herself at the hospital complaining of pain in the back. In May last year she had been told she had spinal disease, so sought advice. The examination revealed great tenderness on percussion over the whole length of the spinal column, and a great amount of hyperæsthesia; she was unable to keep the spine straight by the exercise of her will for more than a few seconds, but swayed from side to side, and then dropped into a chair, if handy, but if not, on to the floor. The uterine functions were all wrong, dysmenorrhœa having existed for two years, and I learned that she was sometimes fifteen hours a day on her feet, in the vitiated atmosphere of a draper's shop. There was also marked globero-hysterical. The case was not severe enough to need a support, so she was treated by the trapeze and cold douche, and all but complete recumbency, with a mixture of Epsom salts and tinct. ferri perchlor. After two months she could stand firm and erect for any length of time, and bear any amount of rubbing and tapping. She continued the cold bath every morning and obtained a situation of less severity, and up to the present time has been quite free from her hysterical spine.

CASE II.—A. D., 30, a widow of six months, had been nursing her husband through a long illness, and was very much broken down; sallow complexion, dark rim round her eyes, perfectly unable to sit up owing to the "giving-way" in her back. When supported by the hands placed in the axillæ the spine could be brought perfectly straight, but relapsed into a state of "limpness" on the support

being removed. The pain was intense on slight pressure, and the cry produced most characteristic. The support was worn for three weeks before she could attempt the trapeze, but at the end of a month she could swing for an hour and *almost* enjoy it. The great difficulty in this case was the cold water, the shrieks and howls that it occasioned rendering it necessary to leave it off, and it occurred to me that a Chapman's spinal ice-bag might do as well if applied for one or two minutes daily. This I found perfectly successful, and after about ten days she was able to bear not only the cold sponge, but the friction afterwards. She had the strychn. and valerian mixture, and although it was quite six months treatment in all, she perfectly recovered.

CASE III.—H. S., 21, medium height, good development, and apparently good constitution, up to eighteen never had bad health. Fell from third storey at that age, and, according to her own description, fractured her skull, and was insensible for fifteen days. Ten days after recovering consciousness she lost the sense of smell entirely. This continued for four months, when violent pain in the back began, the sense of smell being regained. This pain has existed until the present time, the lightest touch anywhere in the region of the spine produced a spasm almost tetanic. She could not raise herself from the couch on which she was lying, nor could she keep herself erect. After determining it was a case of hysterical spine, I, with some difficulty, got her to submit to the cold douche, she bravely persevered, and after a month she could sit up, and we soon began the trapeze, and finally some walking exercise, and four months after the first cold bath she was quite well, and has remained so for more than nine months. I should remark in this case the catamenia, which had ceased directly after her accident, recommenced—scanty at first, but soon becoming normal—directly after the douching had been begun.

I have had several other cases of more or less interest and severity, and I trust I have been able to demonstrate that there is not only such a condition to be diagnosed, but also a good prognosis, and a fairly easy remedy, for hysterical spine.

ON THE METHODS OF DIAGNOSIS IN DISEASES OF THE NERVOUS SYSTEM.

By E. C. SEGUIN, M.D.,

Clinical Professor of Diseases of the Nervous System in the College of Physicians and Surgeons, New York.

LECTURE I.

GENTLEMEN,—I propose to devote this and a subsequent lecture to a brief summary of the methods of diagnosis, more particularly those resorted to in organic nervous diseases, describing the instruments used and showing you how to go over a patient's body and examine it. A knowledge of the methods of diagnosis and of how much trustworthy information they will yield us is very important, and, I think, may be considered with profit. I will have a patient brought in, that I may make such manipulations upon him as are used in forming a diagnosis. Of the functions of the nervous system there are two general divisions: in the first place, the functions of movement; and in the second place, the functions of sensibility. An examination into the psychic functions is of great importance, but hardly a subject for a clinical discourse.

For determining the condition of the functions of movement there are three methods, viz.:—

1st. By means of dynamometers.

2nd. By the performance of passive and active movements.

3rd. By inspection.

1. The instrument which is mostly used in making examinations into disorders of movement is the dynamometer.

* * For the woodcuts illustrating these Lectures we are indebted to the New York Medical Record.

mometer, or strength-measuring instrument (see Fig. 1). There are several varieties of dynamometers. The one I use is the simplest kind, and consists of an elliptical steel spring which can be compressed in the hand or

FIG. 1.

other parts of the body. Connected with it is a cog-wheel which moves an index-needle upon a dial, the index-needle remaining where it is carried by the muscular effort of the patient. The French instrument is provided with a double scale, which I think is altogether unnecessary. Observations made with this dynamometer, when recorded, should be accompanied with a statement as to whether the numbers refer to the inner or outer scale, as the numbers indicated on the two scales differ enormously. For instance, the dynamometer-needle in this patient's grasp points to 200 on the outer scale, and 70 on the inner scale. These numbers are supposed to represent kilogrammes, but I have no faith in the accuracy of such representations. Again, there is no advantage to be gained by knowing the exact number of pounds or kilogrammes of force exerted. A registration of degrees of force is entirely sufficient, and I always speak of the numbers indicated in any particular case as so many degrees. Now, as to the method of grasping the instrument. It should be grasped fairly and squarely in the hand, with the second phalanges resting upon the spring, and should be compressed without resting the hand or arm upon anything, and without giving the arm a swing at the moment of compression, as some patients will do. It is also important to place the face of the dial toward the palm of the hand, otherwise the fingers of the patient may interfere with the movement of the index needle. We know that there is in most healthy individuals a difference in strength between the left and right hands, but we want to estimate it. There are very few healthy individuals with a difference of more than five or eight degrees; a difference of ten degrees would lead to the suspicion of paralytic weakness upon one side. Sometimes we find the left hand stronger than the right. A number of patients are left-handed, and therefore use the left hand more than the right. There are some occupations which tend to develop more strength in the left hand than in the right. Car drivers show equal strength of both hands, or greater strength with the left hand, for the reason that the reins are held in it. I need not go into further details, but will say that you should be on the look-out for these normal variations in making tests with the dynamometer.

My friend Dr. Birdsall has invented a foot-dynamometer, which is intended to record the comparative degrees of strength of either the anterior or posterior tibial group of muscles upon the two sides of the body. It consists (see Fig. 2) of a board with a movable foot-piece, which is grooved so as to receive the hand-dynamometer between the base-board and the movable foot-board. The foot-board is provided with a toe and heel strap, by means of which the foot is secured in position upon it. By placing the hand-dynamometer in the front grooves and strapping the heel down upon the foot-board and telling the patient to lift his heel, the strength of the posterior leg-muscles can be approximately estimated. For testing the anterior tibial group of muscles the ends of the instrument are reversed, the hand-dynamometer being left in position, and the toes strapped to the foot-board. The

patient is then directed to attempt to raise his toes, and in so doing the power expended is transmitted through the heel to the hand-dynamometer. This instrument was brought to the notice of the profession by Dr. Birdsall, in a paper read before the American Neurological Association. Its accuracy is not as great as that of the hand-dynamometer, but, as I have already remarked, we do not care so much for an accurate record of the force expended as we do for a comparative measurement of the force exerted on the two sides of the body.

FIG. 2.

There are registering dynamometers which record upon paper, or other prepared material, the muscular strength and tone of the patient. There are also dynamometers which will register the amount of pulling or pushing force exerted, and so on; but, for practical work, all that is necessary is a good hand-dynamometer.

2. Another method of treating disorders of movement is by handling the patient. The manipulations are made with our hands, and against the patient's will. We are thus enabled to determine the amount of resistance—strength of a great many muscular groups in the body. We lay hold of the patient's limb, having directed him to hold it in a given position, and tell him to resist our efforts at flexion or extension. By having the patient resist downward pressure upon the chin, we can determine whether there be paralysis of the masseters, temporals, or pterygoids. If paralysis exist, a very slight downward pressure will be sufficient to overcome the muscular resistance, and thus open the mouth. We can judge of the condition of the neck-muscles by the movements of the head. We direct the patient to hold his head perfectly stiff and upright, and see how much force is required to move it forward or backward. In a similar way we test the power of the flexors and extensors of the arm. In partial lead-paralysis only a very slight force is required to flex the hand. The short flexors of the hand can be tested in this way, and even the interossei can be tested by lateral movements of the fingers. With the lower extremities we proceed in a corresponding way. To test the quadriceps extensor femoris, we make the patient hold the leg in extension and attempt to flex it. For testing the posterior thigh muscles we cause the patient to flex the leg upon the thigh, and take hold of the foot and pull it forward. The same test which was applied to the hands and fingers can be applied to the foot and toes. The abductors and adductors should be tested in the same way. In little children under three years the condition of the muscles may be examined by what I am in the habit of calling the cataleptoid test; or, more properly speaking, we note the absence or presence of the cataleptoid state in the muscles. I have found that if we divert the attention of a healthy baby and gently place one of its arms or legs in a given position, or in any position, that position will be maintained for several seconds or minutes. The limb is held by an automatic muscular contraction—an exaggeration of the muscular tonus. This normal state I call the cataleptoid state. In paresis or paralysis, more especially in infantile spinal paralysis, the

affected limb, when most carefully placed as described above, falls at once, like lead, in obedience with gravity.

The ocular muscles can be tested by requesting the patient to follow an object about with his eyes without moving his head. Convergent and lateral movements can thus be studied. A good way of testing the interni is to hold your finger at about twelve inches from and in front of the patient's eyes, and move it gradually to within three inches. If affected, one eye or both eyes will diverge. We test the external recti muscles by making the patient follow an object in the outer fields of vision. It must not be assumed in obscure cases that this test is sufficient. There are cases of diplopia which are not revealed by this means. The method by which the oculists determine the existence of latent diplopia is to hold a strip of coloured glass before one eye so as to colour one of the images of the object, and thus enable the patient to distinguish them. Prisms are also used for detecting slight weakness of the recti muscles; but, as this is a part of a delicate manipulation of special eye practice, I need not more than refer to it.

3. The third method is by observing the patient's movements, or by inspection. The tongue is tested by requesting the patient to protrude it, and observing whether it deviates to the right or left, and how far it is protruded. You should guard against error in making the projection test. If the patient has lost a good many teeth upon one side, the tongue may be deviated in consequence, or it may be turned out of line by a cicatrix in itself. The tongue may be deviated by paralysis of one cheek. These sources of error are of considerable importance in a practical way. Facial paralysis on one side is evidenced by a drawing of the features to the opposite side, as well as by loss of expression on the affected side. In paralysis of the orbicularis palpebrarum the eye cannot be closed, &c. The various movements of the arm are to be tried in a systematic way. In evident paralysis, of course, we do not make these tests, but in slight cases we tell the patient to move both arms simultaneously, and note which one moves slower and less forcibly. I will show you a case of ordinary hemiplegia. I ask the patient to hold up both arms, but you see that the paralysed arm does not go up like the other.

By voluntary movements we test the various forms of inco-ordination. We test co-ordination by testing the precision of the movements of the muscles, not their strength. A ready means of doing this for the arm is to request the patient to shut his eyes and try to put the tip of his forefinger upon the end of his nose. Some patients cannot do this. In that form of sclerosis known as disseminated cerebro-spinal sclerosis, and in posterior spinal sclerosis involving the cervical cord, the patient, upon being submitted to the above test, has oscillating movements of the arm and finger, and ends by thrusting his finger into his eyes or mouth. Similar oscillations are shown when the patient attempts to put a key in a key-hole. These resemble closely the movements of a person trying to do the same thing while in a state of acute alcoholic intoxication.

(To be continued.)

LOCOMOTOR ATAXY OF SYPHILITIC ORIGIN.

By Dr. FOURNIER, of Paris; and Dr. DRYSDALE, of London.

ONE of the most contested points in the natural history of syphilis is whether the disease is ever the true cause of locomotor ataxy. Dr. A. Fournier, of Paris, in 1875, alleged, at one of his lectures at the Lourcine Hospital of Paris, that syphilis, when it attacked a certain department of the spinal cord, might be the cause of the disease described by Duchenne and by Trousseau. This allegation has been opposed by many very able writers, but still its original partisan, Dr. A. Fournier, remains of the same opinion.

In France, for instance, Vulpian and Graesset are among the only two clinical observers who agree with Fournier; but in Germany, Erb, Westphal, Remak, Mayer, and Berger gave in their adhesion, more or less, to his views. At the London Medical Congress, again, in 1881, Erb, Althaus, Zambaco, and others, were more or less on the side of Fournier, Lancereaux being, however, quite opposed.

Fournier points out that there are at present four opinions on this point, the first being that ataxia is, in the immense majority of cases, caused by syphilis; the second, that syphilis and ataxia have no connection; the third, that syphilis, when it attacks the posterior columns of the cord, may give rise to symptoms of ataxia, but that it never can cause the systematised type of disease described by Duchenne; fourthly, syphilis may produce ataxia in an indirect manner—not through gummy deposits or syphilitic lesions, but by causing anæmia and cachexia.

In the history of rheumatic affections of the heart by the illustrious Bouillaud, says Fournier, the discoverer assembled a large number of cases of acute rheumatism and a large number of cases of murmurs of the heart, and showed that the latter were very frequently indeed preceded by the former. Fournier proceeded in the same way in trying to ascertain the causation of ataxy, and found at the Lourcine that twenty-four times out of thirty locomotor ataxy had been preceded by syphilis; whilst Sireday found it eight times in eighteen; Fereol, five in eleven; Caizergues, eight in fourteen; Drysdale, five in seven; Erb, eighty in one hundred; Althaus, ninety in one hundred. Fournier asks whether any of the causes ordinarily accepted as the origin of ataxy, such as rheumatism, cold and damp, onanism, venereal excesses, hysteria, moral emotions, &c., can summon such a large number of cases all agreeing in one point. Vulpian adds that syphilis had preceded ataxy in seventy-five per cent. of his cases; Gowers, in seventy per cent.; Erb—lately—in eighty-eight per cent.; Quinquad, in twenty-one; and Fournier—recently—in 107 out of 117 cases seen by him at the Hôpital Saint Louis.

Syphilitic ataxia may arise from six to twelve years after infection; but it also may be seen earlier or later than these dates. In some cases no other cause is seemingly present; in others, again, cold and damp, rheumatism, and excessive work have co-operated. The ages at which locomotor ataxy is most frequently seen are between twenty-four and fifty-nine. It generally commences between twenty-five and thirty-five, or among young persons. It is greatly confined to the male sex; another proof that it is syphilitic, since for one woman who has had syphilis, perhaps ten men have contracted it. Perhaps five per cent. of the cases of locomotor ataxy are to be seen in women. As Dr. Broadbent has pointed out, too, it would seem that it is only in cases of very slight secondary syphilitic symptoms that we are to expect that ataxy may possibly follow; in this respect all syphilitic nervous diseases seem to resemble each other.

Syphilitic tabes has no special symptoms, and has three periods—the pre-ataxic, the ataxic, and the terminal. It is only in the pre-ataxic period that much effect can be expected from specific treatment in this dangerous affection. The pre-ataxic period may be characterised by "lightning pains," by ocular palsies, by gastralgia, or loss of sight, by paresis of the lower limbs, and urinary paresis, by spasms of the larynx, or even by such very contrary symptoms as satyriasis or impotence. The lightning pains are very slight at first, and scarcely felt, but may become extremely painful, and amount in the end to attacks of agony. Local hyperæsthesia and anæsthesia occur occasionally, and sometimes headache and pains in the lower limbs. In about one-half of all the cases there is paralysis of one of the motores oculorum, and the symptoms seen are diplopia, strabismus, mydriasis of one eye, &c.

These affections appear suddenly. The genito-urinary symptoms rarely consist in hyper-excitability; far more commonly in symptoms of depression, such as over-rapid ejaculations, and even complete absence of all desire. The urinary symptoms consist in weakness of the bladder, and tenesmus, or hyperæsthesia. As to the symptoms in the lower limbs, these consist, at the commencement, in a feeling of weight, and constant fatigue in them. Everyone knows the importance of the symptom of incertitude of walking in the dark. The failure of sight consists in amblyopia, or in failure to distinguish colours, such as red and green. Both eyes are affected, but only after a great interval of time does the one follow after the other affection. Blindness may be complete in some four or five years.

The affections of the stomach noticed at the commencement of ataxy are sometimes severe enough to make us believe in the existence of an ulcer in the stomach, or hepatic colic. At other times simple dyspepsia is noticed, which is almost quite unamenable to treatment. In the larynx, too, there is sometimes noticed spasmodic cough, which may resemble the hysteric cough. There may be symptoms of constipation, or incontinence of feces, and tenesmus of the anus.

Sometimes there is well-marked vertigo, which may be aroused by a rapid motion of the head, or quickly descending the stairs. The lightning pains in the head constitute a symptom which often remains unrecognised. There may be anæsthesia of the face, lips, and tongue co-existing with plantar anæsthesia, the latter constituting a very valuable symptom of the disease. In addition to these symptoms, disturbances of hearing may be among the pre-ataxic symptoms, but these are very difficult to understand. The pre-ataxic period is said to last from three to six years, but nothing is more difficult than to determine when ataxia commences.

It is often necessary to seek carefully for commencing symptoms of tabes. To make it less difficult, it is useful, says Fournier, to make the patient walk up and down; to cause him to descend a flight of stairs; to shut the patient's eyes and make him stand with the feet close together, when the smallest oscillations must be noted; to make the patient stand first on one and then on the other foot, with the eyes open, and then shut; lastly, to take account of the sign of "tendon reflex" of Westphal, 1875.

Ataxia, as is well known, consists in a more or less inco-ordination of movement with conservatism of force in them. In the period of ataxia the pains are severer than those seen in the pre-ataxic period. Some patients, however, do not suffer from lightning pains. In addition to these there occurs in the ataxic period, frequently, anæsthesia of the lower extremities, especially of the toes, with analgesia occasionally; disturbances of the genito-urinary system become more common, such as impotence, incontinence or retention of urine, causing the unfortunate patient to be constantly seeking the urinal. The intestines also become greatly disturbed in function, and rectal inertia, with diarrhoea or constipation, prevails.

The skin becomes pallid and dry, and the lower extremities near the metatarsus and toes are sometimes incrustated with a thinner or thicker incrustation, like ichthyosis. The perforating ulcer of the foot is one of the early symptoms of tabes, according to Dr. Ball (International Congress, London, 1881).

Syphilitic locomotor ataxy, according to Dr. Fournier, is not always seen in the form of pure and simple ataxy. It is frequently preceded, accompanied, or followed, by other phenomena not noticed in ordinary ataxy, this last being limited to those symptoms solely which point to a lesion of the posterior columns, with or without irradiation on certain cranial nerves. The mixed or complex forms of tabes are, he alleges, most symptomatic of specific tabes. For instance, in company with the motor inco-ordination there are seen symptoms

of muscular weakness, of paresis, such as the addition of paraplegia to the ataxy. Progressive muscular atrophy may also be seen in the upper extremities in the course of syphilitic ataxia.

Certain cerebral symptoms may accompany syphilitic tabes, such as taciturnity, fits of rage, and strange dreams, or epileptiform attacks may occur, or vertigo; or, again, there may be hemiplegic seizures accompanied by epileptiform seizures. When ataxia has appeared, it may be followed by attacks of epilepsy and aphasia, with congestion of the brain and hemiplegia. Dementia, exaltation, and general paralysis of the insane may also arise from this form of syphilis, and be its final stage. Gradual dementia and depression are the commonest forms seen.

Dr. Fournier speaks of "bulbous crises," as exhibited in loss of consciousness, with cyanosis, slowness of breathing and slowness of pulse.

Writers on insanity had remarked, in syphilitic patients, the association of tabes with general paralysis, and have described this fact under the name of "general paralysis of medullary form commencing with locomotor ataxia."

Fournier has named this "posterior cerebro-spinal syphilosis," and gives several examples of it which are likely to force conviction on the sceptical.

Sometimes the predominance of brain symptoms may be such that the tabes is masked: we cannot too much insist on the fact that these cerebral forms of tabes are peculiarly common in the syphilitic variety. And the same has to be said concerning the epilepsy, the hemiplegia, and the aphasia of syphilitic patients. Syphilis has a marked tendency first of all to multiply its lesions, and then to spread them over different departments of the nervous system.

Fournier mentions a case, seen by Dr. Prevost, of Geneva, where ataxia appeared simultaneously with the early symptoms of syphilis in the period of secondary syphilis.

Treatment.—The treatment of syphilitic tabes ought to be that used in syphilis of the brain and spinal cord; and should be tried as soon as possible, for it is only at its commencement that this affection can be cured. We ought then to act vigorously and to persevere in treatment. Fournier recommends the exhibition of four to eight grammes of iodide of potassium daily (3j. to 3ij.), and three, four, or five centigrammes of corrosive sublimate daily (gr. $\frac{1}{2}$, gr. $\frac{2}{3}$, gr. $\frac{1}{4}$) for three weeks alternately.

If the patient has been long ataxic, nothing can be hoped for from treatment; but, on the contrary, if the affection be not ancient, it may be arrested; if still in its infancy, it may be cured. According to Fournier's own personal experience, two cases were cured only for a time, i.e., in one case for two years, and in another for four years. In eight cases the disease was arrested in its initial forms. So that the Professor of Syphilis of the Ecole de Médecine insists very strongly on the necessity of attacking tabes at its onset, when it is only marked by some ocular paralysis.

It must be noted, however, that although specific treatment is capable of curing syphilides, it cannot cure the scars which are caused by them, and Charcot and Bouchard have shown (Soc. de Biol., 1866) that sclerous myelitis of the posterior columns may exist as a lesion even before it gives any symptoms, so that treatment may sometimes be too late even at the apparent onset.

Professor Fournier has placed so many facts before us in favour of syphilis being the most common cause of locomotor ataxy, that it is difficult to remain any longer unconvinced. Several years ago I read a paper on this point in the Medical Society of London, when I mentioned that most cases of ataxia I had seen had a syphilitic history.

Clinical Records.

TOTTENHAM TRAINING HOSPITAL.

Three Cases of Acute Tuberculosis.—Autopsies.

Reported by Mr. SIDNEY DAVIES, B.A. (Oxon.), M.R.C.S.,
House-Surgeon.

CASE I. (Under the care of Dr. Lichtenberg.)—John D., *æt.* 65, painter, was admitted into the hospital on the 13th of March. From the time of admission he was not quite clear-headed, so that only an incomplete history was obtained. He stated that he had suffered much from rheumatism, for which he had been laid up for two or three months two years ago. From his account, however, the malady appeared to have rather resembled gout than rheumatism. Otherwise he had had good health till two months ago, when he became very weak. Since that time he had suffered from short breath and bad appetite. Three weeks before admission he had diarrhoea. He was sleepy, and started in his sleep. He had been receiving parish relief for eighteen months previously, on account of the scarcity of work. He was addicted to drink, but said not to be a hard drinker. His family history, as far as obtained, was good.

On admission, the skin was dry, rough, and of a dirty yellow colour; conjunctivæ also yellow. Face dry, and rather flushed; tongue somewhat furred. Pulse, 100; temp., 99°. Abdomen rather full, but no marked tenderness in the right iliac fossa. On auscultation, loud harsh breathing, of an almost bronchial character, was heard all over the chest, and a few clicks in different places. Resp., 40. Heart sounds natural. Marked senile degeneration of the cornea. Urine contained no albumen. The patient's mental condition was peculiar; when spoken to he replied with a harsh, hoarse voice, like an injured person in a bad temper. He appeared to understand all that was said to him, but his observation and memory were evidently at fault. He appeared pre-occupied with his own injuries.

The temperature rose to 102.4° on the morning after admission, which was about the average temperature until his death. It remained for the most part constantly above 101°, with very variable remissions, being generally higher in the morning than at night.

March 27th.—Patient very hoarse; will not allow an examination of the throat. Face much flushed. Very light clayey motion seen. Bowels act once a day. Nails much incurved. He continually falls asleep, with loud nasal breathing, and then wakes with a start. He often groans. Pulse, 88; resp., 36.

30th.—Throat examined; fauces congested. Patient has an earthy smell, and very earthy appearance. He sometimes passes his excreta unconsciously. Sleeps much, and groans and starts in his sleep. Localised crepitation, and dry râles heard on the right side, at the base in front, and at the angle of the scapula, accompanied by bronchial breathing, but no dulness. Loud harsh breathing continues all over chest. Pulse is not dicrotic.

April 3rd.—Patient seems a little better in his general condition. The left eyelid droops, and there is slight conjunctivitis of the left eye. He shivers and twitches a good deal. The tongue is moist and thickly coated. Pulse, 100; resp., 22.

4th.—There is a bed-sore on the right buttock.

5th.—Patient can scarcely be roused to attend to what is said to him. The mouth was drawn on one side as if he were trying to speak. Otherwise there are no signs of paralysis. Pupils equal and contracted.

He died on the 6th.

Treatment.—Pil. hydragryri was given at the commencement, but it had no effect on the jaundice. Large doses of quinine were given to reduce the temperature, but without any definite result. The other treatment was merely symptomatic.

Autopsy.—Performed 26 hours after death. Rigor mortis well marked; body not much emaciated. (The patient lost but little flesh after admission.)

Brain.—There was a considerable quantity of fluid in the lateral ventricles, but no tubercles nor inflammation of the pia mater were detected.

Lungs.—No fluid in the pleural cavities. Firm adhesions at both apices, and some loose adhesions elsewhere, chiefly on the left side. On the surfaces of both lungs were some hard rough prominences, the size of a nut. Both lungs infiltrated

from base to apex with grey tubercles and tubercular masses, varying in size from a pin's head to a small pea. There were one or two hard cretaceous masses, about the size of a large pea. There was no cavity, nor any sign of breaking down of the pulmonary tissue, but the bases of both lungs were in a soft, pulsatious condition.

Heart.—There was hypertrophy of the left ventricle, and a patch of atheroma on the mitral valve.

Abdomen.—There was a large sub-peritoneal ecchymosis, corresponding to the lower half of the rectus abdominis. Some loose peritoneal adhesions, chiefly about the spleen; spleen did not extend below the ribs; very soft; weight, 4 ozs. Liver weighed 46 ozs. Intestines not distended. In the lower part of the ileum was a small, oval, transverse ulcer, $\frac{1}{4}$ inch in diameter, with thickened border, and irregular, congested base. In the ascending colon were three ulcers, about $\frac{1}{4}$ inch long, elongated transversely. In the left kidney was a large hæmorrhagic softening, and on the surface a small defined abscess. Pancreas enlarged, chiefly at the hepatic end. Weighted 6 ozs. Tissue very hard and rough.

CASE II. (Under the care of Dr. Rasch.)—William Moore, *æt.* 53, gardener, was admitted into the hospital on May 22nd. He had been ill for seven or eight weeks, troubled chiefly with cough and weakness. He had had insufficient food for some time previously to his illness. He had lost much flesh. The bowels were always constipated, and he had never vomited during that time. But, as in the former case, the patient himself was not sufficiently clear-headed to give his history, nor could much be learnt of him from his friends. He said he had always suffered from a winter cough, and his father had died of a tumour in the back.

On admission he presented in his general appearance a striking resemblance to the last case. His face was flushed and dusky; tongue dry, slightly furred; breathing quick and loud. Pulse, 63; resp., 36. Evening temperature, 101.2°; morning, 98.2°.

Physical Signs.—Large crepitation, with puerile breathing at the left apex, but resonance there normal. Large crepitation at the right base in front. Behind, dulness at the left base, with bronchial breathing and diminished vocal vibration. The patient complained of pain in the left side. Mucopurulent sputa. The abdomen was full and tender, but there were no spots nor any special tenderness in the right iliac fossa.

May 25th.—Motion seen, loose, yellow-green colour, shreddy, with small yellow lumps, and mucus. Morning temp., 100.5°; evening, 102.5°. Pulse, 108; resp., 40. Patient sleeps a good deal, with hard sonorous breathing, often snoring. Takes food well. The patient continued in this state, with a hectic temperature, for about two weeks. If anything, his general condition seemed to improve; but the signs of effusion on the left side increased till the whole side became dull. On June 2nd, after an exploratory puncture, he was tapped with an aspirator, and 29 ozs. of clear serous fluid drawn off; the tapping was stopped while the fluid still ran freely. After tapping, dulness reached to two inches below the angle of the scapula. The patient had several attacks of epistaxis about this time.

June 13th.—All left front and axilla completely dull; bronchial breathing very distant. Back not examined, owing to weakness of patient. Right side resonant; breathing puerile, rough, with one or two clicks. Abdomen very full; tympanitic, with dulness in the flanks, varying on movement. Much mucopurulent sputa. Tongue very dry; motions natural; bowels regular. Patient is delirious, chiefly at night; the pupils are equal, and react to light, and there is no sign of paralysis.

17th.—Tongue dry, glazed, cracked. Conjunctiva and skin yellow. Skin very moist.

The patient was now going rapidly down hill. He was tapped again on the 19th, and 46 ozs. of clear fluid drawn off, but as before, he gained no relief from the removal of the fluid; on the contrary, he seemed rather worse after it. The hectic temperature continued, but it seldom rose above 100°. Rapid wasting, chiefly in the temporal regions, was now apparent, and the patient quickly sank and died from apnoea on the 26th.

The *post-mortem* was unfortunately not completed, owing to the friends demanding to see the body during its progress. The lungs and peritoneum were, however, examined. The right pleura was generally adherent, and the lung was universally infiltrated with miliary tubercle. It was rather congested, and crepitant all over, and showed nowhere any sign of breaking down. The left pleura was distended with a

nearly clear fluid. The lung was completely collapsed and airless, and like the right, infiltrated with tubercle. There were loose pleural adhesions, very numerous and vascular, in the posterior and superior parts of the cavity. The peritoneum was covered with small, light grey tuberculous nodules, varying in size from a pin's head to a lentil. The peritoneal cavity contained a considerable amount of serous fluid.

CASE III. (Under the care of Dr. Rasch).—John B., æt. 52, carpenter, was admitted on the 29th of March. He had been unwell for about six weeks before admission, suffering from frontal headache and colicky pains in the abdomen. A few days before admission he had been treated as an out-patient for slight pleurisy in the left side. Since then his breath has been very short. He had been unable to work for three months, owing to the frontal headache, and at the commencement of that time was treated in the hospital for paralysis of fingers.

On admission, the patient exhibited some dyspnoea. He had cough, with scanty expectoration. The tongue was dry and slightly coated. On physical examination of the chest, crepitation and bronchial breathing was heard at both bases behind, but no other markedly abnormal signs. The abdomen was natural, and perhaps slightly full. There were no spots, and the spleen was not felt below the ribs. Urine clear, acid, sp. gr. 1010, contains no albumen. The temperature was 102°, and subsequently showed daily morning remissions and evening exacerbations, varying from 103° to 100°, the daily difference being usually about 2° Fahr. The patient was sensible and intelligent. The following notes were made subsequently:—

April 20th.—Crepitant râles at the left base; no dulness; no spots on the abdomen. Tongue dry and furred. Headache and pains all over. Patient passed a bad night.

22nd.—Much headache. Tongue very dry and furred. Sleeps badly.

24th.—Headache very severe last night.

27th.—Headache gone. Tongue moist. Patient feels better, and sleeps well, but starts in his sleep. A large, dark, formed motion seen, streaked with blood. The anus was examined, but no piles nor fissure were found. The bowels are fairly regular.

May 1st.—Patient vomited three or four times yesterday, and twice this morning. Slight delirium. Sensible when roused. Tongue cleaner.

3rd.—Severe hiccupping. Pain over left supra-orbital ridge. Uncontrollable vomiting. Delirious, but sensible when roused. Pupils equal, contracted. Tongue cleaner. Abdomen still full.

4th.—Passed his urine unconsciously this morning. Hiccupping and delirium all night. Tongue clean. Abdomen very full, tympanitic. Dulness in the flanks. Rapid wasting of flesh, marked by sinking of the temples.

6th.—Vomiting continues; hiccup less. Patient hardly conscious, but puts our tongue when asked. Dozed all night. Breathing gulpy (jerky). Tongue moist, much furred. The patient died at 7.0 p.m., with stertorous breathing.

The treatment had been purely symptomatic; various remedies were tried to stop the vomiting, but without avail.

Autopsy (forty hours after death).—Body not very emaciated. On removing the dura mater from the upper surface of the brain the arachnoid was found to be partially adherent. Lymph and small grey tubercles were seen in the pia mater occupying many sulci, both on the upper surface and at the base of the brain, in the Sylvian fissure, ventricles, and choroid plexuses. The latter were injected with blood. The opposite sides of the Sylvian fissure were adherent. The costal and visceral pleurae were loosely adherent all round on both sides. There were firm adhesions at the right apex. In the right lung at the apex was an irregular, ill-defined cavity, about the size of a walnut, with very soft walls, showing signs of rapidly breaking down. The whole right lung was very soft and vascular. Both lungs were infiltrated all over with grey tubercles. All the abdominal organs were adherent by firm bands of lymph to each other and the abdominal parietes. The intestines were distended with flatus. At the lower part of the ileum were four old, irregular, cicatrised ulcers. The peritoneal surface of the intestines was in parts congested. There were a few enlarged mesenteric glands. The spleen was small, not reaching to the free border of the ribs. No tubercles were seen in the peritoneum.

Remarks.—These three cases are interesting from their similarity, the difficulty in diagnosis of at least two, and the rarity of acute tuberculosis in advanced life. In all three there were cranial, thoracic, and abdominal symptoms combined, although the head symptoms were most pronounced in one, and lung symptoms in another. All three were men between fifty and seventy years of age. Two of them had been for some time deprived of sufficient food. It is probable that not one of the three had any consolidation or breaking down of the lungs at the apices on admission, though in one there were signs of rapid breaking down having preceded death. This point is important, because most cases of acute tuberculosis in adults are secondary to apical phthisis. It would seem to indicate some external source of infection. In only one case was the diagnosis made with any confidence before death. The other two were put down as probably enteric fever, though the unusual temperature chart and the puerile breathing and head symptoms led me to suspect the true cause in the first case. The third case differed at first in no respect but the absence of spots and diarrhoea from an ordinary case of typhoid with pulmonary complication. The two cases in which the abdomen was examined after death both had intestinal ulcers, but they were evidently tubercular in one, and old in the other, and the small spleens in both cases precluded the supposition that they were typhoid ulcers. The jaundice in the first case greatly complicated the diagnosis. It appeared to be due to pressure of the enlarged (tubercular?) pancreas on the bile duct, the tissue of the pancreas being remarkable hard.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

CURE OF A CASE OF HYSTERICAL CONTRACTION.—At the meeting of the Société de Biologie, M. Chantemesse reported the case of a young girl affected with hysterical contraction, which persisted nine months, and which was cured by the application of metallic plates, according to the method of Burg. This patient had been subject to headache since she was ten years old. When the contraction manifested itself she had attained the age of fifteen; and at this period the headache disappeared altogether. In the month of November she was wounded in the left hand by a piece of broken glass, and immediately stiffness of the muscles set in; and this contraction resisted every means directed against it for many months. In July last the patient entered the Hôpital Beaujon, under the care of M. Fernet, who on examination found there was hemi-anæsthesia of the whole left side, and the already-named contraction of the muscles of the forearm. A powerful magnet was applied to the affected side, and recourse was had to the apposition of different metals—gold, silver, tin, platina, zinc, and copper—but there was no change in the contraction, and the sensibility was in no way improved. At last, about eight days ago, a bracelet composed of steel plates was placed around the forearm, and the next day the whole of the contraction had disappeared, but the anæsthesia was in no way modified. The bracelet cannot be taken off for some time, as the affection would return within forty-eight hours. The election of the metal on the muscular element, the contraction that it caused to disappear, leaving unaltered the special and general sensibility is a phenomenon curious to observe.

CAUTERISING THE CERVIX IN INCOERCIBLE VOMITING IN PREGNANCY.—At the Medical Congress held at Rochelle a member read a paper on "Incoercible Vomiting in Pregnancy, and its Cure by Cauterising the Cervix." He cited seven cases in which this method was tried, and each time with full success. The author concluded by affirming that

the time was come when this evidently heroic treatment should be admitted into medical practice and generalised; and thus many who were otherwise condemned to certain death would be saved. A colleague, replying, said he did not intend to attack the method of his learned friend, but he thought that the number of cases cited was not sufficient in order to convince him that no accident would result from the operation, for it was well known that all manipulations of the cervix in a woman *enccinte* provoked frequently abortion. In any case he would not attempt the operation except in the gravest cases. M. Mauny (the author) insisted upon the fact that in the twelve cases he attended abortion did not occur once. He was far from wishing to apply this method to every case. On the contrary, it was only when all other means were exhausted, and that the life of his patient was in danger, that he had recourse to the caustic.

TREATMENT OF SYPHILIS.—In the treatment of syphilis Dr. Thomaun uses subcutaneous injections of iodoform in glycerine—iodoform, 3iss.; glycerine, 3vj. He commences by injecting six grains of iodoform, and at the end of a few days the dose is raised to ten grains. According to Dr. Thomaun, the syphilitic manifestations rapidly disappear; and there is no abscess at the point of insertion of the syringe. The solution of iodoform should be always recently prepared, as otherwise the iodine is set free and causes violent pain.

VASELINE AND BORIC ACID OINTMENT AS A NON-IRRITANT ANTISEPTIC.—M. Lucas Championnière recommends an ointment of vaseline and boric acid as a non-irritant antiseptic. It is particularly useful for those wounds which it would be important not to irritate. It is very advantageous as a local application in eczema and intertrigo; and in the erythema of infants provoked by the prolonged application of soiled linen, or from other causes, there is no better remedy. Its disinfecting action, though not very powerful, is sufficient. M. Championnière employed it with great success in feet that emitted a bad odour. The ointment was applied between the toes, and the effect was almost instantaneous. The formula of the pomade is—Boric acid, 3iss.; vaseline, 5j. The acid should be employed in fine powder, and incorporated with the vaseline, and not dissolved in alcohol or glycerine, which renders the pomade irritant.

SEVERE EPIDEMIC OF MEASLES AT ST. ETIENNE.—At St. Etienne (Loire) there has been for the last month a severe epidemic of measles, and a great many children have been carried off—meningitis, pneumonia, and diarrhoea being the complications generally observed and the cause of the fatal termination. Grown-up persons have not been spared, although in them the disease never assumed an aggravated form, and no deaths are reported.

DEATH THROUGH EATING POISONOUS MUSHROOMS.—A very sad accident, which unfortunately ended fatally, occurred recently to the Rev. G. T. Dodds, son-in-law of the well-known Dr. Horatius Bonar, of Edinburgh. It appears that Mr. Dodds, who was the collaborator of the Rev. R. W. McAll, the founder and conductor of Mission enterprise in France, left Paris for the country, with his wife and family, to enjoy a few days' well-earned rest. They selected a village in the neighbourhood of Orleans as their abode, and one day he took his family into the woods to pick mushrooms, of which he was very fond. Unfortunately, the children were allowed to help in the search, and it is supposed that they unwittingly picked some of the venomous species. However, in the evening,

after they had all partaken of the mushrooms, symptoms of poisoning set in amongst them all; and as where they were stopping was an out-of-the-way place, medical aid could not be procured till the following day, when Mr. Dodds, who is supposed to have indulged more freely than the rest in the poisonous fungi, was in a prostrate condition, and never rallied. He succumbed a few days later. Mrs. Dodds and the family, which consists of five children, the eldest of them not yet six years of age, have entirely recovered.

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

THE GERMAN IMPERIAL OFFICE OF HEALTH AND KOCH'S EXPERIMENTS ON THE TUBERCLE BACILLUS.

PROF. BILLROTH, during his recent sojourn in Berlin at the Session of the Eleventh Congress of the German Society of Surgery, took the opportunity of making himself more intimately acquainted with this institution than he had previously been, and on his return to Vienna gave a short but interesting account of what he had seen to members of the Society of Physicians of Vienna.

At the present time, when vivisection, the tubercle bacillus, and R. Koch are so prominently before the minds of the medical profession, some of the information he imparted cannot fail to be interesting to your readers.

From the communication thus made we learn that the Imperial Health Office is the creation of the Imperial Chancellor. The building in which the work is carried on is of tolerable size, and contains a fair number of workrooms and laboratories, besides a number of apartments for the lodging of animals intended for experiment. The greatest care requires to be taken to keep the animals in perfect health, as it is known that under unfavourable circumstances they are liable to die off, or to fall victims to tuberculosis. Ventilation is here carried out so carefully that it is only to be wished that our own sick-rooms might equal it. The cages are kept scrupulously clean. Each animal represents an experiment. Besides the Director and a number of fellow-workers (chemists, &c.), there are now several physicians specially occupied with the study of the tubercle bacillus, amongst them Robert Koch—a *R. gierungs-Rath*, or Government Councillor.

As regards the tubercle bacillus, it is known that it has been long sought after, and many have thought they had already discovered it.

Billroth's own words will best express his meaning in the following sentence. He says: "Judging from the whole method of research, and from the clearness and certainty of the process, for me it is beyond a doubt that in Koch's tubercle bacillus we have to do with a scientific fact not again to be cast aside. Years ago I expressed the conviction that these vegetable organisms—and as such I considered the originators and disseminators of tuberculosis—must be discovered."

The Vienna surgeon considers that, notwithstanding the acknowledged genius of Koch, the first and greatest step towards the solution of this problem was made by Villemin, when he proved by experiment that tuberculosis was inoculable. From this time it has been settled that this disease could be transported by a fixed virus. The primary stage is a chemical process in the tissues, whence the pathological changes result. This chemical key we do not yet possess. Here in tuberculosis the chemical agent is associated with

vegetable organisms; the latter are, however, but the carriers and disseminators of this unknown agent.

The tubercle bacillus does not seem to differ from the algae that are already known to us (to which order it belongs) in its mode of development; it resembles other varieties in size and form so completely, that it cannot be distinguished from them by the microscope alone. Through Koch, however, we have been made acquainted with a reaction that separates it from all similar organisms.

Prof. Billroth described the vegetation forms of these algae, how the rods increase in number, how the permanent spores develop, and from these again the rods, &c. Koch was convinced that the tubercle bacillus also developed spores, but that, contrary to what obtained in the case of *bacillus anthracis*, the whole process was completed in the body of the animal. As in the case of large plants, so this bacillus showed its own peculiarities in regard to the soil from which it grew. It had been long known that rabbits and guinea-pigs were easily inoculable, but that, on the contrary, dogs were not. Within the animal, also, the parasite showed peculiarities in its growth; it attacked some organs very readily; whilst in others it remained at the lower stage of development, and rapidly died out. Absolutely uninoculable the dog is not, as Koch has recently shown, but for this parasite he does not offer a suitable soil. Generally speaking, the herbivora are more fitted for the growth of this alga than the carnivora. Barndoor fowls have a high degree of receptivity for the tubercle bacillus, whole yards of fowls quickly dying off.

In the human species the disposition to tuberculosis is a very varied one, and this disposition is handed down from parents to children. Only this is to be understood by the hereditariness of tubercle, viz., the greater receptivity for tubercle infection, which is also outwardly expressed in the bodily structure. A lesser disposition to infection is the great protection of the bulk of the human race.

Another reason why local tuberculosis (Volkmann) so often exists without general infection, why a relatively large number of individuals the subjects of caries of the bones, do not become the victims of general tuberculosis lies in certain mechanical conditions. At the periphery of such tuberculous masses (bones, lymphatic glands) is a thickening, a compact capsule that prevents the emigration of the vegetable organism into the circulation.

Moreover, the plant requires for its development a high temperature—that of the blood—whence the development does not take place outside the body. This difficulty in the way of growth is likewise fortunate for humanity. The spores require a certain period of rest before they germinate afresh, and this is plainly the period of incubation that is observed after inoculation.

From a practical point of view, we know now that tuberculosis is an infectious disease. This, indeed, was believed before now; but we have now obtained a fresh grip, as it were, when we see that the tubercle bacilli are present in the sputa of those patients whose mucous membranes are in a catarrhal condition. Much that we have looked upon as heredity must now be considered to be infection. Thus, for example, a tuberculous mother who ejects a sputum into her pocket-handkerchief, and uses the handkerchief to her child who has sneezed, may infect her offspring. Another source of infection is the intestines, which may become the channel of infection from flesh, or milk from tuberculous cows, &c. ("grapes"). These sources of infection must be studied. The sputa, and the other dejects of tuberculous individuals are also infectious, but certainly in a lesser degree. Pus becomes

horny in drying, and a firmly-seated crust. To examine into this and much more is reserved for the future.

This discovery of Koch's has this beauty in it, that it carries our medical observations into the domain of science; that which has been assured empirically for millenniums finds now its confirmation in natural science.

Special.

EFFECT OF TEMPERATURE ON SEPSIS.

M. H. BOULEY, at the Paris Academy of Medicine, read a paper by M. Paul Gibier, "On the Possibility of causing 'Charbon' Infection in Cold-blooded Animals by raising their Temperature." It appears that the temperature most favourable for the development of the charbon bacteride is that of the normal temperature of mammals—viz., from 37° to 38° C. All birds having a higher temperature than 42° are not subject to the ordinary forms of this disease; but M. Pasteur succeeded in developing charbon bacterides in fowls by reducing their temperature through prolonged immersion of their claws in cold water. After having decided that in water of the ordinary heat frogs do not appear to feel at all a subcutaneous or intra-peritoneal injection of charbon liquids, the question presents itself whether, by raising their temperature to about 37°, charbon bacterides would develop in these cold-blooded animals which have become, for the time being, warm-blooded. This experiment has been tried by injecting frogs with charbon, and forcing them to live in water of 33° to 37° of heat. Out of twenty cases of injection performed by M. Gibier only five were successful. The remaining fifteen died immediately on their immersion in warm water, or in a few days afterwards, without presenting any bacterian subjects, and only two survived entirely. This proves that with frogs, as well as with other animals, there exist individual peculiarities. The length of the charbon bacterides is to be attributed to the slowness of the circulation of this batrachian. The following are facts worthy of notice:—

1. It has been observed that frogs in which the charbon has developed itself fast for a certain period. Healthy animals, when first captured, either resist altogether or die in the space of a few days, without presenting any specimens of bacterides, and without enlargement of the liver.

2. Frogs plunged into water without any transition from cold to warm, and soon after inoculation, died sooner than those which were gradually acclimatised.

3. Lastly, a remarkable fact appears which, perhaps, is more than a simple coincidence. It is that frogs first inoculated in cold water did not die after a second inoculation in warm. Ought we to consider this a phenomenon of vaccination?

It is proposed to make other experiments in this direction; but from the evidence of M. Pasteur and others we can safely conclude that, to make an animal physically opposed to it contract an infectious disease, we ought, first of all, to make ourselves acquainted with the conditions which can confer the morbid aptitude on the subject of our experiment.

THE well-known chemical inventor, Jean Wickersheimer, in Berlin, has invented three fluids, which, while doing no harm whatever to the substances, protect bread, meat, and beer against all influences of temperature, weather and atmosphere, for many years.

 mitted by International Post-office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 4, 1882.

THE CASE STATED AGAINST THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE BY THE ATTENDING PHYSICIAN.

THE recent debates on this subject at the meetings of the British Medical Association at Worcester, and of the Social Science Congress at Nottingham, have made it evident that the subject is little understood, even by the medical profession. Statements have, it is true, been promulgated from time to time, professing to give the experience of the working of notification law in the towns to which it has been already applied, but as these statements have—in all cases—emanated from sanitary officials to whom compulsory notification would be a great convenience, and from those who are enthusiastic for coercion legislation in all matters of public health, it is desirable that the other side of the case should be published for the instruction of those who may have been misled by *ex parte* statements in favour of the proposed general compulsory law.

There is the greater necessity for those to speak out who object to the physician being compelled to notify, because there is imminent danger at this moment of the public and the medical profession being subjected, by legislation in the coming session of Parliament, to new and very serious responsibilities and penalties without having a chance of a hearing in their own defence. So far as notification legislation has yet gone, it has been carried through by civic officials by under-hand means, and generally without any real knowledge by the ratepayers of the intention to put them under

the notification yoke; while the medical profession has not only been unhesitatingly sacrificed for the convenience of sanitary officials, but has been carefully kept in the dark on the subject by the Parliamentary Bills Committee of the British Medical Association, whose special duty it was to warn them of the danger and protect them against the infliction. If this method of legislation be longer tolerated, the public and the medical profession throughout the Kingdom will awake some day to find themselves bound hand and foot by the sanitarians and corporation officials, and compelled to submit themselves or else suffer the fines and imprisonments provided for those who object to be "sanitized" without being asked their opinion on the subject; and we, therefore, consider that the moment has come for calling the special attention of the medical profession and the public to the contemplated legislation.

WHAT IS COMPULSORY NOTIFICATION?

The law of compulsory notification to which we refer has been enacted in certain towns throughout England for the purpose of enabling the civic sanitary authorities to find out each case of infective disease, and to take steps to protect the population against the spread of the malady; and this purpose has been attempted to be attained by compelling the physician in attendance on an infectious disease to report the same to the sanitary authority of the district. Let us say, at once, distinctly, that we entirely recognise the gain to the community likely to accrue from an early knowledge of the existence and *locus* of infective disease; that we are well aware of the danger accruing to the public from the presence of an undetected *nidus* of infection in their midst; that professional experience puts it beyond doubt that much disease is disseminated to the great injury of the public by careless or criminal persons who conceal its existence; and that it is a most laudable purpose to seek to mitigate these dangers by obtaining early information and using all reasonable means to prevent the spread of infection.

But while we thus heartily approve of the *intention* of notification legislation, we, with equal vehemence, condemn the *method* heretofore employed for carrying that intention into effect, and we protest against the apparent determination of sanitarians to perpetuate and extend that method. We assert, in fact, notwithstanding all that civic sanitarians may say, that the methods heretofore employed are tyrannical in principle and ineffectual in practice—that they have failed in their purpose, and will fail all the more, the more coercive in character they are made; and that—if a law to compel notification be indispensable—the duty should be imposed upon the householder or the custodian of the patient, and certainly not on the physician. It is against the means proposed to be adopted that we are contending, and if a wise and practicable scheme for notification of infective disease be propounded, we shall be found amongst its most enthusiastic supporters.

METHODS OF NOTIFICATION.

There are three different methods by which it is proposed that information of the occurrence of infectious

disease shall be conveyed to the sanitary authority, viz.:—

a. Direct Medical Notification.—Where the physician in attendance is obliged to report the case direct to the medical officer of health or his representative with or without the consent of the patient.

b. Indirect Medical Notification.—Where the physician is obliged to hand to the custodian of the patient a written notice of the nature of the disease, which notice the custodian is responsible to send forthwith to the medical officer of health or his representative, the custodian being only responsible to notify on his own account when there is no medical attendant.

c. Dual Notification.—Where both the physician is obliged to send notice and the custodian also, even though a physician is in attendance, and has already reported the case. This system, as will be observed, exists in certain towns as a part of direct medical notification, and is, in fact, a means of securing a report on each case.

d. Householder Notification.—Where the custodian of the patient is alone responsible to send the notice, though there may be a physician in attendance.

Twenty-three towns in England are subject to one or other of these forms of the law.

Direct Medical Notification exists in—

Barrow-in-Furness.*	Llandudno.*
Birkenhead.	Manchester.*
Blackburn.	Oldham.*
Blackpool.*	Preston.
Bolton.*	Reading.*
Burton-on-Trent.	Rotherham.*
Derby.*	Stafford.*
Huddersfield.*	Stalybridge.*
Jarrow.*	Warrington.*
Lancaster.*	Edinburgh.*
Leicester.*	

Indirect Medical Notification exists in—

Bradford.*	Norwich.
	Nottingham.

Dual Notification exists in those towns marked above with an asterisk.

Householder Notification exists only in Greenock.

BILLS BEFORE PARLIAMENT.

With a view to an extension of the notification system throughout the Kingdom generally, there were before Parliament last session three Bills—viz., those introduced respectively by Mr. Hastings, M.P., for England and Wales; by Mr. Gray, M.P., for Ireland exclusively; and by Mr. Meldon, M.P., also for Ireland. The Bill of Mr. Hastings is promoted by the Council of the Social Science Association, of which Mr. Hastings is now President, and Mr. Gray's Bill, which is put forward on behalf of the Dublin Corporation, is substantially identical with it. The terms of Mr. Meldon's Bill will be referred to hereafter.

The following is an abstract of Mr. Hastings' Bill:—

Whereas it is desirable to provide for early notification to sanitary authorities of the occurrence of infectious diseases within their districts:

Be it enacted, &c.

2. This Act shall be read and construed with the Public Health Act.

3. Any medical practitioner attending or requested to visit and attend any inmate of any building in the district

of any sanitary authority suffering from small-pox, cholera, typhus, typhoid, scarlet, relapsing, or puerperal fever, diphtheria, measles, or erysipelas (or other acute infectious diseases . . .) shall immediately on becoming aware of the nature of the disease from which such inmate is suffering forthwith fill up, sign, and transmit, either personally or by post, to the office of the sanitary authority of the district a certificate in . . . form . . . contained in . . . this Act.

4. If no medical practitioner be attending . . . then the occupier of such building, or . . . the person in charge of such inmate, shall . . . forthwith transmit a notice by post to the sanitary authority of the district.

5. The sanitary authority shall supply gratuitously to every registered medical practitioner . . . in the district, and to every inhabitant, upon application forms for the certificate . . . of the occurrence of infectious disease; and the sanitary authority shall pay to every registered medical practitioner who shall . . . transmit any such certificate a fee of two shillings and sixpence in respect of the same; provided that not more than one fee shall become payable to the same medical practitioner for any certificate given by him in respect of any infectious disease occurring in the same building within thirty days of the date of the said certificate. . . . No fees . . . shall be payable for the notification of infectious diseases occurring in workhouses, gaols, or public hospitals.

6. Any person neglecting to transmit any notice required by this Act shall be liable to a penalty not exceeding five pounds.

SCHEDULE.

FORM OF NOTICE.

NOTIFICATION OF INFECTIOUS DISEASES ACT, 1882.

I hereby certify and declare, in pursuance of the above-named Act, that . . . living at No. . . Street, is suffering from infectious disease, viz. . . .

Dated the . . . day of . . . , 188..

Signed,

Registered medical practitioner,
or householder, or person in charge,
as the case may be.

To the sanitary authority of the district of . . .

It will be observed that this Bill proposes to compel the medical attendant to communicate to the health officer of the district for public uses the information acquired by him in his capacity of confidential medical adviser, and it visits him with a fine of £5 (and, of course, imprisonment in default of payment) if, from any cause, he omits to do so. Furthermore, let it be noticed that the Bill, while imposing this responsibility and penalty upon the physician, entirely relieves the custodian of the patient of any responsibility whatsoever in every case in which a physician has visited. For such a proposition we assert advisedly that there is

NO PRECEDENT IN ENGLISH LAW,

and that the promoters of compulsory notification by the physician labour under the difficulty of having to justify a perfectly new departure from the principles of justice and liberty, which have heretofore guided the legislation of our country. The proposal to fine and imprison a physician for not reporting publicly the disease under which his patient suffers strikes at two well-recognised principles of equity—

a. That the person who is responsible for the existence of a nuisance dangerous to his neighbour shall be also the person responsible for the abatement of that nuisance, lest his neighbour may suffer therefrom.

b. That the information acquired by any person in the performance of a confidential function shall be—as far as possible—confidential and inviolate, and shall not be applicable to public uses, save upon extreme public necessity.

In conformity with the first of these principles we insist that the custodian of the infected patient, and he alone, should be held liable to inform the sanitary authority of the nature of the disease; and we challenge the advocates of compulsory notification by the physician to show—under English law—any analogue for the legislation which they propose. What has the law hitherto said upon this subject? When a *nidus* of communicable disease, either in the form of a dangerous nuisance, such as a manure heap, an open sewer, or the noxious emanations of a manufactory, is found to exist, or when an infectious disease occurs amongst the lower animals, who is held responsible to report the existence of the nuisance or of the infection? Let the Public Health Acts and the Contagious Diseases (Animals) Act (taking, for example, those in force in Ireland) answer the question. Under the Public Health Act (sec. 108) it is the duty of the sanitary authority to detect the nuisance, and the duty of the "person by whose act, default, or sufferance the nuisance arises or continues, or, if such person cannot be found, the owner or occupier of the premises," to abate it (sec. 110).

Again, in dealing with infectious disease, what does the law say?—"where any sanitary authority are of opinion . . . that the cleansing and disinfecting of any house . . . would tend to prevent or check infectious disease it shall be the duty of such authority to give notice . . . to the occupier" (sec. 137). And, again, in secs. 144 5-6 the responsibility and penalty for letting infected houses and sending infected children to school is imposed solely upon the "person who shall knowingly or negligently" do so.

The Contagious Diseases (Animals) Act is still more definite on this point. It simply orders the owner of any cattle infected with pleuro-pneumonia or other infectious disease to report the occurrence, or take the consequences—punishing him for default if he omits to do so, and compensating him for loss if he does; and it does not at all touch the question how the owner shall find out the nature of the disease. In no Act of Parliament that we ever heard of is there any proposal such as the compulsory notificationists put forward, that some third party, who is perfectly guiltless of offence against the public weal, but who happens to become confidentially cognisant of the commission of such offence, shall be fined and imprisoned for not reporting the guilt of the other person, while the offender himself is not visited with any punishment whatever.

And this leads us to the consideration of the second axiom of English law above quoted (b), which the advocates of compulsory notification propose to violate.

They propound the perfectly novel and startling theorem that the secrets of the sick-room are legitimate public property, to be forced from those who possess

them, and used for the benefit of the local sanitary organisation; and they scoff at what they call the "sentimentalism" of those who protest against the establishment of a principle so dangerous to public liberty. But let us see whether there is any justification for this proposal in English legal precedents. Has any one ever proposed to force from the solicitor or the barrister, for the protection of the public at large, the confessions of a criminal who, in the absence of the information which the solicitor could give, may remain a danger to society? Not at all. The law carefully protects the solicitor or barrister against even being questioned on such a subject, and English justice refuses to seize by force, as the notification compulsionists would do, the information which does not equitably belong to the community. Again, the confidences of the priest and the physician, though not actually protected by law, are practically privileged. The priest or the doctor in the witness-box may, it is true, be forced, in strict law, to answer any questions put respecting knowledge acquired in the exercise of their professional functions; but the sense of the injustice of such compulsion is so strong in the minds of our judges that it is a universal rule with the bench not to insist upon the priest or physician divulging any matters which are communicated to them in strict confidence.

The only precedent of law by which the notification compulsionists seek to justify the principles which they advocate is the law with reference to death registration, which, they point out, contemplates the medical attendant divulging the cause of death as ascertained by him in his professional capacity. But there is, in reality, no analogy whatever between death registration and compulsory notification. In death registration the whole responsibility to register rests upon the relatives of the deceased or the occupant of the house in which he has died, while in notification, as proposed, the physician is to be the responsible party. In death registration the physician's death certificate is given with the full knowledge and at the request of the deceased's relatives, while in notification the information is to be supplied to the sanitary authority with or without the patient's knowledge or consent, and very frequently against his express wish. Moreover, the analogy completely breaks down when we consider that at death the case as affecting the patient or his custodian is at an end, and no injury or inconvenience can usually result to any one by the act of registration.

Thus, upon a review of the existing law referable to the reporting of nuisances or infection dangerous to health, and to the practice of the courts with respect to information acquired in professional confidence, we have shown that the law which the compulsionists propose is in open violation of precedent and justice as heretofore recognised.

(To be continued.)

THE MEDICAL DEPARTMENT IN EGYPT.

DURING the past week the columns of the daily and other journals have contained comments more or less adverse to the working of the hospital and ambulance services in Egypt. The correspondent of one paper writes

that there is no longer any reason for silence with regard to what he calls "the deplorable breakdown of the hospital service at Ismailia," as he understands that Surgeon-General Hanbury has applied for a court of inquiry, in order that the blame and scandal may be removed from the Medical Department and placed upon the shoulders of those properly responsible for deficiencies such as were only equalled in the Russian hospitals during the late war.

Then, coming to actual details, the same correspondent writes:—"The enormous hospital at Ismailia was opened without drugs, instruments, provisions, or stores, and was unable to supply the front with any medical essentials. There was also an extraordinary lack of hospital attendants. Officers who lay in the wards tell stories which are ludicrous, though painful, of neglect and want of food. All acknowledge themselves grateful for the kindness, sympathy, and skill of the doctors. The fault was not theirs; red tape finished what incompetence began. We shall hear much more of the matter, as several officers personally appealed to Sir Garnet Wolseley, and told him that they were literally starving. Now that it is over, every regiment has its story on the subject."

Another correspondent, describing certain alleged shortcomings in other branches of the service, writes:—"But there was something much more grave than this, more hopelessly mismanaged, something which might have produced terrible results indeed, if the war had been protracted—if the Arab had not always run away. I refer to the Medical Department. Happily our battles were few, and so were our casualties. Had they not been so, the men would have perished like rotten sheep, for want of necessaries. Let those who are responsible deny it, if they dare."

Much more in the same style has also appeared, to which on the present occasion it is needless to refer farther than to suggest on the part of the public patience until fuller and more complete details than are as yet available shall appear. No better man than Surgeon-General Hanbury could be found for his work, although it is very natural that his seniors, many of whom are equally, although no more fit than he, should feel hurt at his appointment. Let due credit, therefore, be given to him for making the most of the means at his disposal, and in the meantime let our judgment be reserved.

In opposition to the statements just alluded to, others have appeared, the tendency of which is to minimise or explain away the shortcomings complained of. For example:—According to published reports from medical officers on the spot, the Khedive's palace at Ismailia was occupied as a hospital on the 27th August. At first there was, "as might be expected, a great *apparent* confusion in the working of the hospital," but the care of the sick and wounded was well and thoroughly accomplished. The men of the Army Hospital Corps were overworked, but upon the whole the arrangements are stated to have been considered satisfactory by Sir Garnet Wolseley. On the 3rd of September, it is stated that Brigade-Surgeon Veale had "in two days, from *chaos* reduced it to a workable system," everything on that date going "as smoothly as possible."

According to another and subsequent report "the military

operations (from Ismailia) commenced before the medical officers, the Army Hospital Corps, or the hospital stores had arrived for the base; consequently, for the first week or two there was a deficiency of nearly everything. Cooking-pots, pannikins, basins, medicines, surgical dressings, &c., all had to be landed from the ships and unpacked, whilst at the same time, the sick and wounded were coming in all through the day and night. Of course, the accommodation afforded by the palace hospital soon became inadequate to the requirements. Tents had to be pitched; the *Carthage* was almost immediately filled with sick; and considerable drafts of invalids were sent away to Malta, England, and Cyprus."

A military journal observes that "it would be hypercritical at present to comment on the lack of foresight and the insufficiency of transport provided at Ismailia, and the want of medical stores equal to requirement." The same journal quotes from "a medical eye-witness, not a member of the Army Medical Department," that, "as for the base hospital (at Ismailia), the arrangements, ventilation, and surgical work would do credit to any London hospital." The comment then occurs that "everything was subordinated to the military exigencies of the campaign. It was imperative that the troops at Ismailia should be pushed to the front with the least delay. Transport being almost *nil*, the advancing column outmarched all supplies; the sick, therefore, of necessity suffered with the rest; but the field hospitals were sent forward with all speed, and medical aid for the wounded was available almost as soon as the casualties occurred." From the above remarks one thing, at least, is clear—Dr. Hanbury has acted rightly and well in making application for a court of inquiry.

THE SANITARY CONGRESS.

JUDGED by whatever standard may be adopted, the Congress of the Sanitary Institute of Great Britain, at Newcastle, has been an undoubted success. From the point of view of the hygienist, however, the proceedings will most probably be regarded with the greatest amount of satisfaction, for it is in connection with practical prevention that the main conclusions of the meeting have been arrived at. Invaluable as all papers read at the Congress have been, there are certain of them whose importance it would be difficult to over-estimate. The opening address of the President will be effectually serviceable both to show the direction in which progress has been made in the past, and the lines along which it must proceed in the future if we would consolidate and extend existing advantages. Minds only "practical" in their reasoning may have some difficulty in appraising the due importance of Captain Galton's insistence on the teachings of experiment; but when they consider the part of the address referring to questions of pure sanitary engineering, they will not scruple to adopt every theory which demands the carrying out of reforms attended with such evident blessings as are secured in all communities regulated on sanitary principles.

Perhaps one of the most cheering signs of progress that could be presented to us is found in the willingness of practical workers not only to listen to,

but to be guided by, the advice given by such authorities as the President at the Sanitary Congress. A good deal of Captain Galton's success is no doubt due to the force of his expressions and the conviction he is able to carry by his words; however little acquainted a man may be with moot or difficult scientific questions, he can at once understand and appreciate the assertion that pure air and pure water afford almost absolute safeguards against most forms of zymotic disease. Indeed, we might accept this statement as the text of the address from which it is extracted, for the burden of Captain Galton's speech was mainly to demonstrate the mode in which the two elements become vitiated, or to show in what manner their purification is to be obtained.

Again, when we are told we shall probably be led to appreciate more fully the advantages of good sanitation if we can arrive at putting a money value upon some of the more direct results of sanitary improvements, an appeal is at once made that is safe to ensure attention at least, if not also conviction. The illustrations afforded by means of results obtained on sewage farms is fully as potent as Captain Galton has evidently assumed it would be; and even a money benefit computed in diminished death-rates and sickness is an argument that now will carry weight, chiefly, however, it must be admitted, in consequence of the patient teachings of Captain Galton and fellow-labourers of his in the field of popular instruction on health subjects.

The paper communicated to the Congress by the Hon. F. A. Russell is one that deserves, and doubtless will obtain, a great amount of consideration. The principle its author insists on has long been recognised in medical practice, though Mr. Russell carries his deductions farther than they have yet been systematically followed by other observers. The aim of his paper is to demonstrate the improvement of climate at a slight elevation; it opened with a contradiction of the once commonly received opinion that temperature regularly decreases with increasing altitude. Observations conducted at various stations have shown that it is not so, but that at points naturally or artificially raised above the surrounding district the range of temperature is smaller. A further conclusion, and one more generally familiar, is that the ground level atmosphere of any district is at times in each day absolutely injurious, and recognition of this fact is accorded by all thoughtful physicians in the advice given by them to delicate patients. It deserves, however, to be much more commonly taken into consideration, not only with respect to convalescents or diseased persons, but as regards every member of a family. In many cases at present illness is assuredly induced, in the first instance, by constant habitation of rooms half, or wholly, below ground, and which exist in all "basemented" houses in big towns. The evil influence of a ground floor dwelling is intensified in underground apartments, and were the Legislature fully alive to the loss experienced by the country each year through the existence of such houses, they would be forthwith condemned as unwholesome and dangerous health-destroyers.

Mr. Russell's enthusiasm leads him to compare the advantages of residence in the higher apartments of a house with those derived from sea-side living, even to the extent of

claiming for the former a larger share of benefit. We may very well omit, for the time, to lend much encouragement to such views, since the chief point illustrated—viz., improvement with removal from the ground—is sufficiently evident to meet with universal acceptance when once it is urged. Whether we should go so far either as to desire that all our dwelling-houses should be exalted on arches sufficiently above the earth to avoid unpleasant and injurious emanations may be left unsettled; but we may with all propriety emphatically insist on the necessity for abolishing the basement system in constructing modern houses. It is true, unfortunately, that this mode of building has been forced by the exaggerated prices fetched by city and suburban land, but it ought to be avoided, even though thereby space is not economised to the full. The ultimate loss is a national one, and is of sufficient magnitude to justify a full consideration of its causes, and their removal by legitimate means, however severe in their consequences at first.

In Mr. Mitchell's address on the Dependence of Fatal Diseases on Weather Movements will also be found much food for profitable reflection. Depending as it does on statistics for its importance, it necessarily shares the weakness to which statistical demonstrations are subject; but, notwithstanding, it takes high rank as an important contribution to etiological science. The principal conclusion to which Mr. Mitchell arrives through his studies is that all diseases exhibit a preference for hot months, in which they act with increased intensity, and are attended with increased fatality. He suggests that there may even be annual epidemics of all diseases.

There is matter enough in the papers read at this Congress for much profitable discussion, which it is to be hoped will be fully given to them.

Notes on Current Topics.

Young Soldiers in Egypt.

It may be remembered that when the expedition to Egypt was being fitted out, a careful selection was made of the men who were to proceed with it, the weakly and the immature being eliminated. Thus, it is to be considered that only such men as were of robust physique and already trained as soldiers were employed on that service. According to published accounts, within a few days from the disembarkation of the troops at Ismailia, a good many men had already become weakly from hard work, or had to return to that place on account of the same cause when the advance began. It was noted on the 5th of September that many of the men were merely weakly and unable to stand the sun. These men do not appear to have required hospital treatment, and this circumstance accounts for the remark made that the young soldiers were not predominant there. In contrast, however, the statement occurs that the 60th Rifles had few men in hospital, and that the battalion was very healthy, "because they were seasoned, and have been campaigning recently in South Africa." The statement also occurs that by the 6th of that month four hundred men had been invalided to Malta and England,

and that four hundred more were then inmates of the hospital at Ismailia ; taking, therefore, these particulars as given, they indicate a very large ratio of non-efficiency, and that it was chiefly among the *unseasoned* men.

Coming to the battle of Tel-el-Kebir, a military contemporary quotes from a correspondent, thus :—" With no desire to disparage the valour of our young soldiers, I must record the universal opinion that success would never have crowned their efforts had it not been for the officers' heroic conduct. The fact is, the men required an immense amount of leading, which is proved by the fact that no less than twenty per cent. of the killed were officers, which is a very high proportion." The same evening, after the action, we learn that many of the men, suffering from exhaustion, had to go to the field hospital, as they were unable to march with their regiment to camp, which was about three miles from where the entrenchments were carried. These men seemed to give way only when the excitement was over. Exactly so. And the particulars thus sent from Egypt bear an important significance in more than one respect.

Basements.

PREVALENT as the system of building houses with a portion of the living rooms below the level of the ground has become in London and other large towns, it is, notwithstanding, a matter of grave concern in connection with the health of the people. At length the injurious influences exercised by unhealthy surroundings of all kinds are receiving close attention, and, in its turn, this question of "basemented" dwelling houses is destined to arouse a very considerable share of attention. At present it has not been definitely attacked in its actual shape, but it is clearly apparent that one of the principal consequences of Mr. Russell's address on Altitude in relation to Health, delivered before the Sanitary Congress last week, at Newcastle, will be a lively discussion on the inappropriateness of existing house arrangements for ensuring plentiful supplies of good and fresh air. According to Mr. Russell's figures, the upper storey of an ordinary town residence offers advantages in respect to atmosphere equivalent to those obtainable at a coast watering-place, while he so emphatically condemns the air at and immediately above the surface, that his advice is to build all dwellings in future on raised arches. Nor is this apparent refinement of caution at all unnecessary ; for in even the most salubrious situations there are periods during every twenty-four hours at which the surface atmosphere is absolutely injurious to the human constitution. How much greater danger, therefore, must be risked by those whose lives are principally spent in rooms that are in cases even a yard or more *below* the ground ? In city warehouses, and in those miles of streets which go to make up a modern suburb, no unimportant portion of the establishments is situated below the ground floor level ; and in such subterranean apartments hundreds of thousands of men, women, and children are daily shortening their existence by exposing themselves to the dangers that lurk in the atmosphere surrounding them. It may not, perhaps, be too much to hope that as the truths contained in Mr. Russell's address are explained and understood by the masses, their own sense of self-preserva-

tion will be a factor in determining whether speculative builders shall in future play with stakes represented by human lives.

"Sanitation" in Egypt.

AN officer of high rank in the Army Medical Department has been specially attached to the army serving in Egypt in order to watch over sanitary affairs generally in relation to that force. At Ismailia "the sanitary state" of that place—whatever the expression was meant to imply—was being carefully "looked after," and, it is to be hoped, improved, by that officer. Yet there were two items to rectify which some little difficulty presented itself, namely, the heat of the sun and the character of the water of the Freshwater Canal. The mixture of sand and soil on which Ismailia stands rapidly absorbed filth of all kinds, and the heat of the sun evaporated the liquid portions. The palace in which the wounded are accommodated consists of a series of large apartments with numerous doors and windows, so that overcrowding and insufficient ventilation could hardly be obtained, even were persistent endeavours made to gain such an end, and were no "sanitary officer" within a thousand miles of it.

According to the most recent information received we learn that the amount of sickness in the force in Egypt has undoubtedly been large ; so large, indeed, that upwards of 2,000 sick will have to be provided for in the hospitals at Netley and Woolwich, and that the capacity of those establishments is likely to be thus severely taxed. Eighty years ago, and when there was no "sanitary officer" with our forces in Egypt, those troops suffered only from diseases that were in their nature climatic. Now, notwithstanding the presence of the functionary so named, they suffer from affections due to similar causes, and which no measure of scavenging—otherwise "sanitation"—ever did, or ever can, prevent.

Small-pox at the Cape.

ACCOUNTS from the Cape give the worst possible description of the ravages being committed in the colony by small-pox ; the number of cases under treatment is very large, and the resources of the authorities are taxed to the utmost to cope with the disease. From advices received here it seems that long before the outbreak had assumed its present proportions, the question arose of meeting the exigencies of the situation aright, and the *Cape Argus* essayed to point out the course that should be pursued. The question of remunerating those medical men on whom fell the work of combating the disease had to be discussed, the newspaper deprecating any repetition of a former occurrence when the services of practitioners were improperly or not at all rewarded. We may be quite sure that our brethren at the Cape will not be backward, under any circumstances, in lending all the help they can to check the disease, but at the same time it is the duty of the State that benefits to be forward in recompensing labours which so materially assist it. As the *Argus* affirms, the exercise of a medical man's skill is as worthy and as necessary to be paid as the services of any follower of a profession or a trade. And although the surgeon can never refuse his aid, whatever certainty he may have

that he will never be remunerated for his labour, it is nevertheless a bounden duty with those in whose power it lies, and who are responsible, to render payment for that which has been done in their favour. Much, therefore, as it is to be regretted that the point has been raised of necessity, there can be little doubt but that it has long ere this been permanently and satisfactorily settled.

The Metropolitan Railway.

On Monday, of last week, a new station was thrown open for the public use on the underground railway, this now extending to the Tower. It is, moreover, certain that before another year has passed the "inner circle" so long debated and deferred, will be completely laid, and in working order. The event thus foreshadowed is one of considerable importance to the profession, inasmuch, as we pointed out at the time when the works now in progress were commenced, many persons who now are debarred from the advantages offered by East-end hospitals, and particularly the London, will be enabled to utilise every opportunity that presents itself of extending clinical experience. As a medium for locomotion, too, so far as the City of London generally is concerned, the completed "inner circle" will be an unmistakable boon; and the speedy fulfilment of long-held hopes is a subject calling forth universal satisfaction.

The Medical Examinations of the Royal Irish University

Have just concluded. We hear that about 90 students—almost exclusively from the Queen's Colleges—sent in their names for examination, of whom 77 actually proceeded to the test; 72 of these went through the entire examination, and of these 39 passed; the rejections being, therefore, 46 per cent. For the Licence in Midwifery, we understand that 28 offered themselves, of whom only 13 passed. These figures afford a gratifying assurance that it is not the intention of the University to sell its degrees to every bidder, but to maintain a reasonably high educational standard. Such a policy is as wise in the interest of the University as in the public interest, and we earnestly trust that it will be adhered to, no matter what party may object.

Hospital Saturday Fund.

THE President and Committee of the Metropolitan Hospital Saturday Fund, we are informed, confidently look for a large increase in the aggregate collection this year. From what has already come in, it is believed that it will reach £10,000, as against £8,500 last year. So far, the collection-sheets show an advance upon preceding collections, notably that of the Royal Arsenal, Woolwich, which was only £55 last year, but which will be upwards of £100 this. The street collections realised £2,300, and it included over two tons of bronze coins, which were found rather difficult to dispose of. Last year the street collection was £250 less. The collections on board some sixty river boats of the London Steamboat Company averaged 20s. a boat, the highest being £5 16s. 9d., and the next £3 19s. 5d. Last year, although the boxes remained on board the boats for several days, the aggregate receipts

were only £51. Applications to participate in the present year's collection have been received from 64 hospitals, 35 dispensaries, 5 convalescent homes, and 2 surgical appliance societies. We trust the committee will carefully scrutinise the doings of these surgical appliance societies, which still persist in putting applicants for relief to the degrading and vexatious delay of begging for letters. On the whole, the Hospital Saturday Fund seems to be making its way amongst the working men, since it is more generously supported by them, though as yet the measure of their support is by no means commensurate with the advantages they derive from hospitals and dispensaries.

Death of Dr. Lewis.

THE General Post Office has lost one of its most familiar *habitués* by the death of Dr. Waller Lewis, which occurred a few days ago. The deceased physician had long been principal medical officer to Her Majesty's Postal Service, in which capacity he annually published reports on the health of the Post Office *employees*, many of them affording very valuable information. Dr. Waller was a Graduate in Arts and Medicine of the University of Cambridge, and a Member of the Royal College of Physicians. He was also Foreign Secretary of the Epidemiological and a Fellow of the Geological Societies. In recent years Dr. Waller has been less personally active than during his earlier life, but among a very large circle of personal friends he was both well known and highly appreciated. The valuable vacancy his death creates has already excited much competition.

Workhouse Hospitals as Centres of Clinical Instruction.

A STARTLING report, which we believe to rest on the best foundation, reaches us, to the effect that the Senate of the Royal Irish University, notwithstanding a unanimous warning uttered by their medical sub-committee, has resolved to accept certificates of clinical study issued by Irish workhouse medical officers. We are not able to say whether it is intended to accept such evidences of hospital study for the entire period required by the regulations, nor do we know whether the Senate intends to require any guarantees of teaching capacity from workhouse hospitals before they place them on the list of institutions recognised, but the establishment of the principle involved is sufficiently important to require earnest notice from us.

In the interest of clinical teaching in Ireland, and of medical education generally, we must unhesitatingly condemn the course adopted by the Senate, because we do not believe that union hospitals are, or ever can be, efficient centres of medical teaching. We trust when we have said this that we will not be understood to cast any doubts upon the professional capacity of Irish union medical officers, whom we know to be as a rule excellent working practitioners, and men of industry and intelligence. But they may be all this, yet altogether unfit to undertake the teaching of medical students, and we go so far as to say that there is not even one union hospital in all Ireland which is capable of performing that function efficiently. For what is the *raison d'être* of the workhouse hospital?

Is it not essentially for the purpose of receiving and treating infirm paupers, whether or not their cases be suitable for clinical purposes? The union surgeon has no power to select his cases; he must admit all persons who need medical help and cannot get it at home, and, necessarily, his wards are incumbered with a multitude of chronic cases of no clinical value whatever. Again, we ask, is it likely that provincial surgeons, separated far from the centres of medical teaching and the sources of the freshest information, will either desire or be competent to undertake the instruction of pupils? and, if they were, we should like to know where—in any workhouse in Ireland—are the appliances for doing so? Where are to be found in such establishments the ophthalmoscope rooms, the instruments for physical diagnosis, and other essentials of hospital instruction? Echo answers, where?

As to the equally important question whether the Irish Local Government Board can allow workhouses to be applied to other purposes than those for which they were originally intended, we at present express no opinion. It is sufficient for the present for us to say that it is our belief that the clinical certificate of a workhouse hospital must necessarily fail to represent the requisite amount of clinical instruction, and that unless the utmost circumspection be exercised there is a very serious danger of the curriculum being flooded with paper of very doubtful value.

The Long-continued Use of Lime-water with Milk.

At a recent meeting of the Medical Society of the County of Albany (*Med. Annals*), Dr. Bates presented a paper on this subject, in which he suggested that the long-continued use of lime-water and milk may result in the formation of a cement of casein and lime, which will prove a mechanical obstacle to the function of the bowel. Two cases were reported, both of typhoid fever, where milk and lime-water was used. In both cases the patients (when convalescent) were taken with severe pain in the abdomen; the first case died unrelieved after ten days. In the second case the rectum was found filled with dry stony-hard fæces, when broken presenting a grey glistening appearance, resembling cement. These were removed mechanically every day, the paroxysms recurring for eight days, when they ceased and the patient recovered. The discussion was unfavourable to Dr. Bates' theory, which was considered untenable. There is so little lime in lime-water that the quantity taken to produce mechanical troubles by its presence would have to be enormous. Milk alone will prove very constipating to some persons, and will produce just such hard, glistening, greyish fæcal masses as described by Dr. Bates, and they will have to be removed mechanically, causing the patient the most excruciating pain.

MR. EDWARD LUND, F.R.C.S., Professor of Surgery in Owens College, Manchester, has been compelled, on account of ill health, to resign the post of Surgeon to the Manchester Royal Infirmary; but in consideration of valued services and the esteem in which he is held, he has been unanimously elected Consulting Surgeon to that institution.

Induction of Anæsthesia.

FROM a communication read by Dr. Johnston to the Medico-Legal Society of New York on Anæsthetics, the following items have been selected as being of importance from a jurist's point of view:—1. The induction of anæsthesia stimulates the sexual function; the ano-genital region is the last to give up its sensitiveness. Hence, a charge of assault during anæsthesia made by a female should be received just as if it were made by an insane person—that is, it should be received and investigated, but the rule *corpus delicti aliunde* should be insisted upon, and, unless some other testimony be forthcoming, the informant should be considered as under a delusion. 2. In operations on the ano-genital regions, and in the avulsion of the toe-nail, complete loss of sensitiveness in these parts should not be allowed, or, if allowed, should be superintended by men who know the danger of perfect anæsthesia. 3. Chloroform cannot be given to persons who are asleep without waking them by anyone who is not an expert. Even experts fail more often than they succeed in chloroforming adults in their sleep.

Scarlet Fever in London.

THERE can be no doubt as to the soundness of the view propounded by Sir E. H. Currie at the meeting of the Metropolitan Asylums Board, on Saturday last, that it is unfair to saddle one district with the patients suffering from infectious diseases of another. Yet this is what is now being done in London in the case of persons stricken with scarlet fever. The Government fever hospitals in the West and North—Fulham and Hampstead—have been closed for some time, in consequence of the disappearance of small-pox; and now that scarlet fever has evinced unmistakable signs of development, the managers of the Deptford, Stockwell, and Homerton Hospitals find themselves unable to cope with so large a demand upon the resources of the several institutions under their charge, and with reason call for the immediate re-opening of the hospitals in West and North London to accommodate the patients from these districts. In accordance with this view, the following resolution was, after considerable debate, carried:—

"That, having regard to the fact that there are at the present time 500 cases of fever in the several hospitals under the control of the managers, and only vacancies for the accommodation of 35 cases of scarlet fever, and also to the fact that many of the patients recently received into the Homerton, Deptford, and Stockwell Fever Hospitals are from parishes and unions in the neighbourhood of the hospitals in Hampstead and Fulham, the managers do make application to the Local Government Board for permission to re-open the Hampstead and Fulham Hospitals for the reception of fever patients, more especially for the treatment of such cases as may arise in the parishes and unions in the vicinity of those hospitals."

THE death is announced of Mr. Clover, F.R.C.S., lecturer on anæsthetics at University College Hospital. As the originator of a chloroform inhaler which bears his name, and as a frequent writer upon the subject of anæsthesia, his name has been for years past associated therewith. Mr. Clover had been in ill health for some time, so that the announcement of his death will fall with regret, but not with surprise, upon those who knew him.

The Next Meeting of the French Science Association.

PROF. PARROT has been nominated President of the Health Section at the next Congress, which will take place at Rouen in 1883. That for 1884 will be held at Blois.

THE Secretary of State for War has appointed William Beale Wallis, Esq., L.R.C.S.I., Brigade Surgeon, to be Visiting Surgeon at Colchester under the Contagious Diseases Acts, 1866 to 1869, vice W. W. Weld, Esq., resigned, from the 25th ult. inclusively.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were: — Brighton 11; Bolton 12; Norwich, Bristol 14; Blackburn, Halifax 16; Birkenhead 17; Derby, Edinburgh 18; London, Portsmouth, Plymouth 19; Leeds, Glasgow 20; Cardiff, Salford, Bradford, Leicester, Huddersfield 21; Birmingham, Sheffield 22; Hull, Oldham 24; Liverpool, Wolverhampton, Manchester, Newcastle-on-Tyne 25; Preston, Dublin 26; Nottingham 27; Sunderland 28.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 26, Bombay 23, Madras 33; Paris 21; Geneva 10; Brussels 20; Amsterdam 21; Rotterdam 21; The Hague 22; Copenhagen 26; Stockholm 24; Christiania 17; St. Petersburg 41; Berlin 25; Hamburg 20; Dresden 23, Breslau 30, Munich 25, Vienna 21, Prague 23, Budapest 27, Trieste 22, Rome 18, Turin 21, Venice 26, New York 30, Brooklyn 28, Philadelphia 21, and Baltimore 24.

A GIGANTIC hydropathic establishment called Seaford House was formally opened last week with considerable éclat, by the Earl of Latham, on the sea coast at Seaford, near Liverpool. This class of establishment is greatly on the increase throughout the kingdom, inasmuch as greater privacy, quiet, and more moderate tariff are obtained by visitors than at hotels. There is, moreover, generally a resident physician on the premises, with the most approved system of baths, so that the increasing patronage accorded by invalids and others in search of health is not to be wondered at.

WE are informed that the Marquis of Hartington, as Secretary of State for India, has officially declined to receive any further communication or deputation from the Indian Medical Defence Fund, on the ground that he fails to see that "it would be to the advantage of the public service, or conduce to the interests of discipline." Thus red-tapism, the bane of all effectual reforms, once more steps in and says, we cannot recognise the abuse of which you complain, because it would not be according to discipline. But those most intimately concerned are not disposed to let the matter end thus, petitions to Parliament being the next step on their programme.

THE annual death-rate from diseases of the zymotic class in the large towns last week, which had steadily

declined in the four preceding weeks, further fell last week. The highest annual rates from scarlet fever were 1·8 in Sunderland, and 1·9 in Derby; from whooping-cough, 1·1 in Manchester, and 1·4 in Oldham; from measles, 1·1 in Sheffield, and 3·5 in Sunderland; from fever, 1·3 both in Sunderland and Derby, and from diarrhoea 4·3 in Hull, and 7·5 in Preston. A death was referred to yellow fever in Bristol. The 31 deaths from diphtheria included 17 in London, 5 in Glasgow, and 4 in Leeds. Small-pox caused 5 deaths in Newcastle-upon-Tyne, 2 in Nottingham, and 2 in the suburban districts around London.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

ROYAL INFIRMARY, EDINBURGH.—Several sums of money bequeathed to the Infirmary have been paid during the past financial year. It appears, however, that a considerable sum is still required to clear off the remaining debt on the new buildings; and the managers therefore appeal to the liberal friends of the Infirmary to assist them in getting rid of this burden. It may also be stated, that as the greater part of the building will have to be refloored, owing to the existence of the dry rot, the drain on the funds will be greatly increased during the ensuing year.

THE ASSISTANT-SURGEONCY TO THE ROYAL INFIRMARY.—Dr. Charles Watson Macgillivray is a candidate for this appointment, and has issued his letter of application and testimonials. Judging from these and the known devotion of Dr. Macgillivray to the study and practice of surgery, few, if any, can show a better claim to the office. He is also a lecturer on surgery in the Medical School. The appointment, therefore, to which he aspires will greatly assist him in his systematic and practical teaching, and he has our good wishes for his success.

EDINBURGH.—HEALTH OF THE CITY.—The mortality in Edinburgh for the week ending with Saturday, the 23rd ult., was 75, and the death-rate 17 per 1,000. Under 1 year there were 14 deaths, and above 60, 23, of which 7 were above 80. Diseases of the chest accounted for 19 deaths, and zymotic causes for 3, of which 2 were scarlet fever and 1 diphtheria. The intimations of new cases of zymotic diseases numbered 93, comprising, fever 4, scarlet fever 80, measles 4, and diphtheria 5.

FEVER IN DUNDEE.—At a meeting of the Sanitary Committee of the Police Commission of Dundee, held on the 28th ult., Dr. Anderson submitted a report on the prevalence of fever in the town. A long discussion took place on the subject, at the close of which a committee was appointed to wait on the directors of the Royal Infirmary to ascertain what accommodation could be provided in that institution for fever patients, and it was also agreed to open the Fever Hospital at the back of the Law, used at present for those afflicted with small-pox, and to erect a small-pox hospital if necessary.

GLASGOW.—CITY DEATH-RATE.—For the week ending with Saturday, the 23rd ult., the death-rate of Glasgow was 20 per 1,000 per annum, as compared with 23 in the preceding week, and 19, 21, and 18 in the corresponding weeks of 1881, 1880, and 1879.

THE NEW MEDICAL SCHOOL, EDINBURGH.—Further portions of this school, which forms the medical portion of the

niversity, will be open for occupation this winter, and it is to be regretted that owing to the want of funds the class rooms of *materia medica*, medical jurisprudence, and chemistry, which are to be located in the north and west sides of the north quadrangle, are still unfinished, and likely to remain so for the next eighteen months or two years. This condition of matters is certainly not creditable to Scotland, or to those who owe so much of their present position and influence to the knowledge gained within the portals of this time-honoured seat of medical education. The University next year is to celebrate its tercentenary; it is to be hoped, therefore, that every effort will be made to complete the buildings, or at any rate ensure the continuance of the work, so that the distinguished visitors who will be invited to do honour to the aged but vigorous *Alma Mater* of some of the most brilliant workers in literature, art, science, and medicine may not find the work on the buildings stopped for want of funds.

FEVER HOSPITAL ACCOMMODATION IN EDINBURGH.—The subject of the proposed arrangement between the managers of the Royal Infirmary and the Corporation of Edinburgh in regard to the maintenance of the Fever Hospital was, we understand, under the consideration of the Infirmary managers at their meeting last week. The details of the arrangement, the leading features of which have already been indicated, in our last impression, not having been adjusted, it was agreed, in the meantime that further consideration of the matter should be delayed.

THE INTRODUCTORY ADDRESSES.

At several Metropolitan hospitals the opening of the current winter session was celebrated on Monday last by the delivery of so-called "Introductory Addresses," and which are chiefly modelled on a plan already familiar by frequent repetition. Subjoined will be found abstracts of most of these orations.

ST. GEORGE'S HOSPITAL.

At this hospital, Dr. Herbert Watney, the lecturer, spoke of the new examination instituted by the Royal College of Surgeons, to be held by the teachers of anatomy and physiology. He considered that it will be only a guide and help to the ordinary hard-working student, and will be so easy as not to discourage any, but will prevent the first year of student life being partially wasted, as has sometimes been the case.

A short account was then given of some of the sciences bearing on medicine. The importance of anatomy, the foundation of the medical sciences, and of physiology, being insisted on, it was pointed out that there is danger of overrating the importance of minutiae in both subjects of study. Pathology was described as being at present divided into two great branches—one, which may be fairly classed as belonging to the two sciences of anatomy and physiology; the other quite different in its character, aiming at much deeper knowledge, seeking to discover the causes of certain diseases, even, it is said, cultivating these causes, and so controlling them that they become innocuous. The great necessity for the study of pharmacology was next referred to, and the study of *materia medica* was alluded to as being only a "survival."

The value of hygiene was then spoken of, and the change in the death-rate of the population during a number of years was considered a clear indication that hygiene is giving us most valuable aid in our struggle with disease.

Dr. Watney then attempted to answer the question, What should be the due relationship between the scientific and the practical in the training of the student and in his after-life as a medical man? After showing that there is generally an intimate union of these two apparently opposite principles in those whom we regard with the greatest respect, he proceeded: A scientific education implies study with a view to the acquisition of knowledge apart from any ulterior

object; that is, seeking to know what has been accomplished in any subject, and to be so placed that future progress is possible, supposing that the patience and abilities of the individual are equal to such advance. It should, however, also include the acquisition of the scientific method. Practical education implies the study of any subject in such a manner that we can bring our knowledge to bear at the present or at a future time. He said it cannot be too strongly insisted on, that the study of the sciences bearing on medicine will not alone enable you to become a safe guide in surgery or medicine; these last have to be studied; they have their methods and instruments of precision, some of which, such as chemical reagents, are well known to the chemist; others, as the thermometer, to the physicist; yet it is impossible for any physicist or chemist, or even for those who have studied the sciences more nearly allied to our profession, to understand the value of certain phenomena, taken in conjunction with others, unless they have studied medicine itself. Therefore, in answer to the question, What is to be the relationship between the scientific and the practical in your course of study? I would say, If you wish to follow the practice of medicine, do not devote too much time to the study of the sciences; they are to be only portions of your education; they are the sources of much knowledge, but they are not the knowledge itself.

The address concluded with practical advice to students as to their mode and course of study, and to the aims which they should continually hold in view.

THE LONDON HOSPITAL.

Mr. Jonathan Hutchinson, senior surgeon to the Hospital, delivered a short address at the London before a crowded audience, which fully appreciated the wisdom he exhibited in avoiding the shoals that prove so fatal to many introductory orators. Mr. Hutchinson devoted himself to the consideration of culture as an aid to medical practitioners, and by exciting the interest of his younger hearers in great questions of scientific and philosophical speculation, he did much to stimulate them to make acquaintance for themselves with the broad facts of scientific belief. Mr. Hutchinson's well-known sympathy with liberal educational systems, and his hearty advocacy of culture and refinement in study, served to excite expectations which his address fully realised. After its delivery a concert was held.

ST. MARY'S HOSPITAL.

Dr. Chambers's "Introductory" at St. Mary's partook somewhat of the nature of a farewell. He said that, though he had resigned his office on the staff, and ceased to walk the hospital with the students, he still sat in their interests on the Medical Council, and could not do better, perhaps, than take for his subject, "The Relation of the Medical Council to the Medical Student," claiming for the Medical Council the credit of the great improvement which had taken place in the status of the medical student by the enforcement of a matriculation or preliminary examination, which compelled parents and guardians to give the student a good general education. Dr. Chambers took the opportunity of warning students against accepting places as assistants before passing the final or "qualifying" examination. When, however, they had cleared examining boards off their minds, then, indeed, he did not know a more valuable part of education than could be got by a good assistantship. Another boon which the students owed to the Medical Council was the division of the examination into several parts, with an interval of time between them. Much more time was thus given to the testing process, and they had fuller opportunities of bringing out their acquirements and showing that they had enough to entitle them to practise. He thought instruction should be less professional and more tutorial, and he felt satisfied, from observation not limited to medical schools, that the catechetical was, of all methods, the most sure and effectual instrument for teaching. He then bade a farewell to the school.

THE MIDDLESEX HOSPITAL.

The circumstances in connection with the opening of this Medical School were of the most painful character. It had been announced that Dr. R. Wishart Lyell would deliver the inaugural address, but at the last moment Mr. Nunn, F.R.C.S., Consulting Surgeon, was called upon to perform the duty, on account of the sudden death of Dr. Lyell. The

announcement cast a gloom over the proceedings, and Mr. Nunn's expressions of deep regret were shared in by all present. He then briefly referred to the subject of vivisection, remarking that although it was regarded in ancient times as a crime, it was now looked upon as a necessity for the advancement of medical science. He next proceeded to give some advice to the students regarding the necessity of regular attendance at lectures, and also as to the benefits to be derived from a judicious occupation of their spare hours.

ST. THOMAS'S HOSPITAL.

After giving reasons for having chosen as the subject of his address, "Some Characteristics of Modern Medicine," Dr. Sharkey referred to the early history of the art and to "the ignorance, superstition, and imposture" which resulted from its being entirely in the hands of the priests. He said that notwithstanding the sound scientific methods which Hippocrates long ago laid down, the progress of medicine had been an interrupted one. "Though a plant of gradual growth it had passed through the greatest vicissitudes. From time to time it had burst into bloom, warmed by the glow of some enthusiastic genius; and then again it had languished almost to extinction under the withering influences of unscientific culture or neglect." Dr. Sharkey then pointed out that proper methods are futile unless employed in the right direction, and that really scientific medicine has only gradually become possible by the progress which has been made in the sciences which are its foundation.

"The great characteristic," he said, "of modern medicine consisted in the union of anatomy, physiology, chemistry, physics, and pathology to form the compound science of medicine, and in the clear appreciation of their necessary interdependence. There was a time, and that not so long ago, when most of these subjects were thought to have but little to do with the actual practice of our art, when physiology and pathology were talked of rather as subjects to be mastered by a few learned professors, to be more or less familiar to a certain number of leading practitioners, and to be all but ignored by the great mass of the profession. But things are so no longer."

"What has really given medicine a claim to be placed among the sciences is the recognition of physiology as its basis; and what has given physiology itself precision is the experimental method of investigation. We do not for a moment assert that without vivisection there would be no physiology; but the irreconcilable opponents of the former cannot even be convinced of the great advantages which have resulted to physiology and to medicine alike from the practice of experimenting upon living animals. The fault, however, lies with the anti-vivisectionists, and not with us. For the foundation of modern medicine is physiology; and one of the essential factors in accurate scientific physiology is experiment. To appreciate these propositions one must first appreciate the facts and history of physiology and of medicine. But this cannot be done, though some insist that it can, by people who have little or no knowledge of these sciences. The answer to those who would suppress vivisection lies, not in quoting individual useful applications to medicine of facts which have been discovered entirely by vivisection, but in pointing to the comparative precision which pervades the whole of modern physiology, and which is being gradually introduced into practical medicine, a precision which we owe to experimental methods of research." In answer to the question "What has been the effect of the rapid progress of scientific knowledge on the actual practice of medicine?" Dr. Sharkey referred to the great advances which had been made in the diagnosis at the bedside of the exact nature and situation of morbid conditions, owing to improved methods of physical examination, and to the numerous instruments which had been invented for that purpose. Increasing knowledge had also produced greater power of prognosis, or the foretelling of the future course of disease. Dr. Sharkey went on to say, "however essential prognosis and diagnosis may be for the welfare of patients, their great test of the efficacy of our art naturally lies in the results of treatment! What can be said of this? Have improvements in the treatment of disease kept pace with the advances in pathology and diagnosis?" This he answered in the affirmative, though, as he remarked, "the methods used do not always appeal to the feelings of the public in the same way as if we dosed them with medicine." Dr. Sharkey's concluding remarks on modern treatment were the following:—"To sum up, then, what can be said of

the principles of modern treatment? We have thrown down the idol of universal specifics, which men had hewn out of false conceptions of disease. We have set up in its place rational scientific treatment founded upon the knowledge of physiological processes in health and in disease; and we aim, as far as drugs are concerned, at the discovery by observation and experiment of the physiological action of substances which can then be used with greater precision in therapeutics. And although this rational pharmacology is still in its infancy, we already possess some drugs the action of which we fairly well understand. We have a few remedies which appear to have just claims to the title of specifics, and we still harbour a probably legitimate hope of discovering others which may be effectual in certain diseases before they have produced serious organic lesions. Great strides have been made in medical surgery, and we seem likely to advance still further in this direction. But our grandest aspirations lie in the path of preventive medicine, a department which should not only embrace attempts to exterminate some diseases, and to diminish the number of persons who fall victims to others; but must likewise include efforts to prevent the extension of morbid processes which have already begun in the organs of our patients, by regulating their lives in accordance with the teachings of physiology.

"It has often been remarked that the best physicians use few drugs, and, compared with the whole contents of the Pharmacopœia, the rational scientific physician will have only a small number of remedies which he cares to prescribe; but, making himself by constant observation more familiar with their action and with the conditions to which they are applicable, he will use them rather as arms of precision, and his treatment will be to the point and effectual, while what may be called the 'Mitrailleuse' system of the less sceptical practitioners of former days relied rather upon the number of substances which were mixed together, in the hope that some might hit the mark!" After referring to the many medical sects and systems which had flourished and decayed, and commenting on the absurdities of the last of them—homœopathy—Dr. Sharkey concluded thus:—"The day has long gone by when systems of medicine were admissible. There is but one system—the scientific—which rests upon observation and experiment, and upon the application of science in general as a guide to the knowledge and treatment of disease. Therefore avoid being led astray by the seductive theories of any sect whatsoever. Be neither homœopaths nor allopaths, nor antipaths, nor any other 'paths,' but scientific medical men; and if you really are such you will secure one of the greatest sources of happiness through life—one of the greatest consolations in its many uncertainties—an enthusiasm for your profession. And having that, you cannot fail to feel also a love and enthusiasm for the school where you first became imbued with the principles of scientific medicine."

UNIVERSITY COLLEGE.

The address in the Faculty of Medicine at this institution was delivered by Marcus Beck, M.S., F.R.C.S., who commenced by drawing a comparison between practitioners of the present and the past, and pointed out how the advance of scientific medicine and surgery was the outcome of exertions made by a few highly educated observers. Referring to the apprenticeship system, he remarked that education by apprenticeship was, perhaps, fairly adapted to the knowledge of the time. It was useless for a student to spend years in the study of sciences which were not sufficiently advanced to be of any real practical service to him in his profession, and the mental training he would have derived from such a course of study would have been of but little use to him, when from the insufficiency of the means of observation at his command, it could seldom have been possible for him to arrive at a conclusion as to the nature of a case by any logical process of reasoning. The instruction communicated to him by his master included a great deal that was true and useful, for much as Science has done for us since that time, we are still as yet very far from being independent of traditional and empirical knowledge. Under such a system of training it was, however, impossible for any but men of great original genius to break away from the trammels of tradition, and to take any part in the advancement of knowledge.

On the subject of test examinations, Mr. Beck insisted that it was devised for the benefit of the school, and not of the student, ignoring the fact that the school was made for the

student, not the student for the school. It had never been instituted in the College, and he hoped it never would. The real effort to meet the higher standard must not be by such tricks as these, but by adopting the best possible course of training to enable the student to think well and correctly, and so more easily to acquire the necessary amount of knowledge; and in this we must be guided by the laws of scientific education.

For zoology and comparative anatomy it is, Mr. Beck fears, almost impossible to claim any great practical utility. The exact knowledge of the anatomy and life history of the various parasites that infest the human body has done something to enable us to prevent their attacks, but even in this respect it is far behind botany. If any subject had to go from this part of a medical education, zoology and comparative anatomy would probably be generally considered the one.

The fault of education a few years ago was that it was too theoretical, and contained nothing in it to take the place of the practical instruction given so abundantly in the old system of apprenticeship. This has, however, of late years been corrected by the institution of practical classes, and compulsory hospital appointments, until, at the present time, the student probably gets quite as much practical instruction in every branch of his profession, except pharmacy, as he did under the old system.

Alluding to the insufficient preparation of students in natural science, he observed a large number of our students start on their medical education thoroughly badly, and the consequence is that they spend a great part of their first year of study in learning how to learn, and doing that imperfectly. From want of training in generalization and classification, their knowledge consists merely of a mass of disconnected details, and the strain upon the memory becomes correspondingly great. A thorough and clear comprehension of a subject is essential for its easy acquirement; and without some knowledge of chemistry and physics it is impossible to understand a great part not only of physiology, but of medicine and surgery also.

After an exhaustive review of the advantages of a scientific training to medical men, he continued: Thus, while the practical surgeon boasts of the marvellous results of modern operative surgery, he should not forget that it is in reality to the discoveries of modern science that he is indebted for the safety with which his operations are performed. The study of the unhealthy processes in wounds is still advancing, in the hands of Koch and others, but there still remains much to be done. Unfortunately, in this country, the means of carrying on such investigations are surrounded by so many legal difficulties, that we are obliged to trust chiefly to foreigners for new matter, but we can take our share in applying the discoveries of foreign pathologists to the practical treatment of diseases, and to prepare us for this, a proper scientific training is necessary.

The concluding portions of the address dealt principally with the same subject of scientific education, its advantages, and the best mode of obtaining it, reference being finally made to the pressing need for amalgamation of the examining corporations.

WESTMINSTER HOSPITAL.

THE introductory address at the Westminster Hospital was delivered by Dr. de Havilland Hall, and was chiefly devoted to advice to students as to their conduct whilst at the hospital, and as to their career in after-life.

Dr. HALL expressed his approval of the examination recently instituted, at the end of the first year, and of the choice of anatomy as the subject for mental training, and he advised that every opportunity of dissecting should be seized, so that the student might acquire a practical knowledge of anatomy, as well as the manual dexterity which is almost as important to the physician as to the surgeon. He deprecated attendance in the wards until the primary examinations had been passed. The advantages of the Durham degree in medicine for those who are unable to obtain the degrees of Oxford, Cambridge, or London were pointed out. After insisting on the utility of lectures, he quoted Carlyle on the necessity of thoroughness. He then spoke of the importance of attention being paid to the physical needs of the body. "In the first place, the demands upon a man's energy and decision are of the most imperative nature. No one who has witnessed a death from post-partum hæmorrhage can deny this. Then, again, in his daily intercourse with disease, good health is absolutely required if the medical man is not himself to fall a victim to

the very disease which he was called upon to treat. Lastly, the irregularity of life, as regards meals and rest, is enough to try the most robust constitution." As a means of preserving health, regular daily exercise was advised, and the importance of the student's mind being clear and tranquil insisted on, as mental work done against the grain was of little value. Dr. Hall subsequently proceeded to examine in detail the different careers open to the recently qualified medical man. He pointed out the modes of commencing general practice, with their respective advantages, and afterwards gave an account of the different branches of the public services. The address, which contained little to interest the outside world, being devoted to subjects affecting the medical student, concluded with an appeal to those present to act up to the spirit of the Hippocratic oath, which was read *in extenso*, and the enlightened morality of which was highly commended.

Correspondence.

AMPUTATION OF THE SCROTUM FOR ELEPHANTIASIS ARABUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have the honour to request that you will kindly give insertion to the following remarks on Dr. G. A. Turner's letter, which you published in your last issue.

Dr. Turner is evidently very much annoyed with me for publishing the quotation from his letter, but in my opinion he should be much more so with himself for his ungenerous conduct to me. If there was not time to communicate with me between his learning that I was in the land of the living and the reading of his paper, there was ample time before its subsequent publication in the *Glasgow Medical Journal*—a period of nearly two months; but he made no effort to do so. I think it highly probable, if he thought about me at all, he thought that, being on the Continent, I would never hear anything about his paper, and so all the inaccuracies which I have pointed out, and for which he has apologised in the *Glasgow Medical Journal* and *Lancet*, would have escaped my notice. Why did he allow ten years to elapse without publishing my cases, though he had promised me most faithfully to do so as soon as the results were known? I wrote to him three times, but never received an answer. He has, however, assured me that none of my letters ever reached him. Last June I accidentally discovered his present address, when I wrote to him, and for the first time learned that he had published his paper; and I think I have every cause to complain of the manner I am treated in that paper, for he indirectly accuses me of pirating the invention of the clamp, and of having taken my ideas of the operation from that of the late Dr. O'Ferrall, which I think I have satisfactorily shown to be the reverse of truth in my paper which you did me the honour of publishing in your issue for September 6th. My operations were the first in which the penis and testicles were preserved to the patient. Dr. Turner in his operations has done nothing but follow my lead, although he makes the following statement, which would imply that he had: "And laid the foundation for the subsequent success with which I met in the treatment of them."

Yours very truly,

G. V. MACDONOGH, M.D.

Wiesbaden, 30th September, 1882.

THE DEBATE ON NOTIFICATION AT THE SOCIAL SCIENCE CONGRESS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A resolution was adopted by the Public Health Section of the Social Science Congress in approval of the principle of Mr. Hastings' Bill, which proposes that the medical attendant shall be compelled, by fine or imprisonment, to report to the sanitary authority every case of infectious disease coming within his knowledge. Least it may be assumed that the Section gave its deliberate sanction to this proposal, I think it well to inform you of the exact circumstances. After a debate which lasted four hours and a half, and in which the speakers against the proposal were almost as numerous as its advocates, a motion was unex-

pectedly proposed, no notice whatever having been given. The motion declared that the Section endorsed Mr. Hastings' Bill, which was not before the Section at all—had not been even mentioned in the debate, except by the mover, and was entirely unknown to the great majority of those present. As it was manifestly improper that the Section should be pledged to approval of a measure of which it was ignorant, I desired to move "the previous question" as an amendment, and, if I had been permitted, I am satisfied that my motion would have been carried by a large majority. To my astonishment, it was ruled by the chairman, Sir Rutherford Alcock (who is a well-known compulsionist), that no amendment of any sort could be entertained, and that a yes or no vote should be taken on the merits of Mr. Hastings' proposal. Such a question being put from the chair, the great majority of those present declined to vote, and a small minority of the Section decided the question affirmatively, as your report stated. No doubt use will be made of this vote to support Mr. Hastings' Bill in next session of Parliament, but I think it will be agreed that an expression of opinion forced without notice and without permitting any alternative proposition to be considered is entirely valueless; and I am further of opinion that the ruling of the chairman was altogether unconstitutional, and at variance with the usage of the Congress or any other public assembly.

I am, &c.,

ARCHIBALD H. JACOB, M.D., F.R.C.S.
23 Ely Place, Dublin.

ARMY, INDIAN, AND NAVAL MEDICAL SERVICES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the subject of competitive examinations is attracting so much public attention, I beg to offer the following suggestions, as certain to inspire more confidence with reference to the examinations for the above-named services:—Firstly.—That, instead of each candidate's name appearing at the top of his paper, which is at present the rule, he shall be provided with a number, as is usual at other competitive examinations, and that he shall be known to his examiners by *number only*, and *not by name*, during the various stages of the examination. Secondly.—I would also suggest that the unsuccessful candidates be informed of the marks awarded them in each subject, so that they may be enabled to calculate their chances of success in the future, instead of reading blindly to attain an object which a glance at their marks would have shown to be beyond their abilities. The unsuccessful candidates for the Indian Medical Service are furnished with their marks; what object is there in not extending the system to the Army and Naval Services?

I am, &c.,

Sept. 28th, 1892.

MEDICUS.

Literature.

MANUAL FOR THE PHYSIOLOGICAL LABORATORY. (a)

WE are glad to welcome a second edition of this handy little volume. That it has supplied a want is shown by the fact that the first edition has been exhausted in less than two years.

The first and greater part of the book is devoted to the minute anatomy of the tissues. It is true that our shelves are somewhat overstocked with text-books of practical histology, but in the present instance the subject is treated in a less elaborate manner. The description of the method of preparing each tissue is followed by a short epitome of the leading facts to be noted in connection with the tissue in question. It is very questionable, however, how far this epitome is of real value. It makes no pretence of describing the points which are to be specially observed in the particular preparation under observation; it is simply a concise and, we may add in all cases, a very lucid account of the minute anatomy of the

tissue under consideration. This, it seems to us, is a sad mixing up of practical and systematic instruction. Indeed, in many respects the first part of the volume might be looked upon as a condensed account of systematic histology in which the mode of preparing each tissue is given, and in which the whole is prefaced by a chapter upon histological methods.

In the description of the various forms of microtome, the authors begin by noticing Ranvier's instrument, and then state that Stirling's "is upon the same principle." This is perfectly true, but at the same time it is apt to mislead the reader and make him infer that Ranvier was the inventor and that Stirling merely modified the original instrument. The first section-cutter was made by Stirling. Ranvier removed the clamp and screw by which it is fixed to the table, and by this simple alteration his name becomes associated with it. Rutherford, on the other hand, retains the clamp and screw, but devises a metal box which he places round the well to hold a freezing mixture, and the instrument henceforth becomes transformed into "Rutherford's microtome."

The second and third parts of the book are devoted to brief accounts of the leading facts of chemical and experimental physiology. Altogether, it is a manual well suited for the use of the medical student, but it is a volume which would be of little value for independent work. The guidance of a teacher is essential.

LECTURES ON THE PATHOLOGY AND TREATMENT OF LATERAL AND OTHER FORMS OF CURVATURE OF THE SPINE. (a).

WE must congratulate the author upon the fact that, although eighteen years have passed away since the first edition of his book was published, nothing which he then stated as to the nature, pathology, or morbid anatomy of spinal curvatures has he found necessary to modify in the present issue. Mr. Adams' opinions upon deformities of the spine are so well known to members of the medical profession, that it is scarcely necessary for us to devote much space to them here, but we will point out a few of the more important of the principles of the pathology of the affection which Mr. Adams has persistently and so ably advocated.

It has been a common custom with writers upon deformities of the spine to adopt some *system* regarding the origin of lateral curvatures, amongst which may be mentioned primary disease of the bones, muscular contraction, and above all, muscular debility. Mr. Adams opposes all *systems* and states his belief that "lateral curvature of the spine may not only be produced by a variety of local causes, but that at the different periods of life at which it occurs, it is associated with various constitutional conditions."

"According to the generally received opinion as to the mode of production of lateral curvature, this deformity is supposed to depend primarily and essentially upon muscular debility, with a lax condition of the ligaments of the spine; structural changes in the bones and inter-vertebral cartilages taking place only at a late period."

But Mr. Adams considers that the affection very often occurs quite independently of debility, and he states that he has seen it occurring in boys of a "healthy and robust appearance associated with more than ordinary muscular strength." The theory of the production of lateral curvature which this author has advanced is that when from any cause the spine is frequently bent to one side the articular processes become so altered from pressure, that rotation of the vertebrae is produced, and he believes "that rotation takes place at the commencement of spinal curvature, and forms an essential part of the series of structural changes which must necessarily exist in slight as well as in severe cases." The inter-vertebral cartilages are also, this author believes, altered in shape at the outset of the affection.

With regard to rickets as a cause of curvature, Mr. Adams is opposed to the view that such cause is common. He believes that the spine is not affected with rickets independently of the other bones, and even where lateral curvature occurs in rickety patients he assumes that the curves take place at a later period than in the cases essentially depending upon constitutional and hereditary causes, that the curves are generally independent of the rickets, or as a consequence of shortening of one leg from curved tibia.

(a) "Manual for the Physiological Laboratory." By Vincent Harris, M.D., and D'Arcy Power, M.A. Second Edition. London: Baillière, Tindall, and Cox. 1882.

(a) "Lectures on the Pathology and Treatment of Lateral and other Forms of Curvature of the Spine." By William Adams, F.R.C.S., Surgeon to the Great Northern Hospital, &c. Second Edition. Churchill, 1883.

Mr. Adams has doubtless based this opinion upon the observation of a large number of cases; but while agreeing with him that the spine has not a very great tendency to rachitic softening, yet we have seen a large number of cases of lateral curvature in young children which we believe to have been undoubtedly due to the constitutional affection. In Mr. Chance's tables of 600 cases of rachitic deformity in different parts of the body which he examined, 108 presented lateral deflexions of the spine which he considered to be rachitic, and in all these cases there were also curvatures of other bones, which were unmistakably the result of rachitis.

Mr. Adams separates the causes of the affection into (1) predisposing and (2) proximate; an arrangement which should, we consider, commend itself to all writers upon the subject.

In discussing the various theories of the production of lateral curvature, Mr. Adams refers to the use of stays and tight lacing. He does not believe that the deformity is ever produced by such means, and he quotes Mr. Tamplin in support of his opinion, as follows:—"Various causes of spinal curvature have been assigned by numerous writers; amongst others, the use of stays, which most certainly of themselves do not produce this deformity, *for they are worn by all classes of society*; whereas the rich and affluent are the most frequent sufferers from spinal affections."

The assertion so frequently made that lateral curvature is more common among the rich than among the poor is probably correct, but we have seen so many cases among the poorer classes of society that we cannot admit that the argument is a conclusive one.

Pursuing this subject further, Mr. Adams makes the following statement:—"We all know that it is only when a girl by her growth and development shows the usual signs of womanhood that stays are thought necessary to improve or mould her figure; and in the present state of public opinion against stays and tight lacing, it is so little the custom of mothers to allow their daughters either to wear stiff stays or to lace tightly, that it would be difficult to find any examples of the practice; they may at least be said to be rare exceptions to the general rule." We fear that Mr. Adams takes too favourable a view of the opinions of mothers upon this subject, for we believe that at no period has the custom of tight lacing been more admired and indulged in than it is at the present day.

The theory which attributes to the custom of wearing stays the origin of the majority of the cases of lateral curvature of the spine is doubtless an erroneous one. Many cases, as Mr. Adams remarks, occur during childhood, before stiff stays are commonly worn, and even of those cases which occur during girlhood, few, if any, can be attributed *entirely* to the use of stays. But we urge that, if other causes be present, such as general debility, as a predisposing, and some bad habit of position as an exciting cause, then the use of stays, inasmuch as they induce weakness of the dorsal muscles by interfering with the due exercise of those muscles, will materially assist in the production of this deformity. Debility of the dorsal muscles has not existed in more than half the number of cases which have come before Mr. Adams, and he attributes the deformity when occurring in individuals whose dorsal muscles appear to be strong, to bad habits of position alone, or to that cause coupled with general debility. He has also met with a great many cases of lateral curvature in patients who showed a predisposition to the development of tubercle in the lungs.

There are a great many other points upon the nature of this deformity in this book which we should be glad to discuss, but the space at our disposal will not admit of our doing so.

We must refer the reader to the book itself, which well displays the care and accuracy with which Mr. Adams has studied the pathology and symptoms of this disorder. With regard to treatment, we must admit that we are somewhat disappointed, for although under the author's careful management the cases which he has treated have doubtless been usually much benefited, and frequently cured, yet our anticipation that some improved method of mechanical treatment would have been forthcoming has not been gratified. The old-fashioned spinal instrument by which it is endeavoured to prop up the body with crutches is still the basis of the apparatus which Mr. Adams employs.

We quite concur with the author that plaster-of-Paris

jackets are worse than useless, and we do not believe that poroplastic felt jackets are much better.

The general principles of treatment advocated in this work are excellent. Due importance is accorded to constitutional remedies, to avoidance of bad habits of position, to carefully regulated exercises, and to the many other items of treatment peculiar to individual cases. Mechanical treatment is doubtless absolutely necessary, and highly beneficial in the treatment of the majority of cases, and the apparatuses which are described in this work can be, and are, used with very good effect, if properly managed; but we had hoped that the great experience which Mr. Adams has had in the treatment of lateral curvature of the spine would have enabled him to have devised some modification of his instruments which would have removed from them those elements of constraint to the body which are so often objected to by other surgeons and physicians.

We have criticised this work freely, but we have read it with pleasure as well as with profit, and we recommend our readers to study the book and judge of its merits for themselves.

Obituary.

DR. THOMPSON, LISBURN.

UNDER circumstances of a most lamentable character Dr. William Thompson, of Lisburn, was killed in his own district on Friday week. The sad event, which cast a gloom over the whole district, occurred at the Dunmurry Station on the Great Northern Railway, shortly after eleven o'clock. The deceased gentleman, while crossing the line, and heedless, it is said, of warnings, which, unfortunately, he was unable to hear—was struck down by the engine, and so seriously injured that death took place in a few minutes. It was then ascertained that the engine had struck deceased on the temple, and so great was the force of the blow that he was thrown to the other side of the platform, a distance of several feet. Dr. Wilberforce Arnold happened to be at Dunmurry at the time, and hearing of the sad affair, was in immediate attendance, only to find, however, that life was extinct. A superficial examination of the body disclosed the fact that the deceased had sustained a severe contusion of the temple, slightly fracturing the skull immediately above the eye, and a broken arm, probably caused by the terrible fall. The deceased, who was 76 years of age, and who will long be remembered as "Dr. Thompson, of Lisburn," had been resident in that town for the last 45 years, and has been practising medicine since 1828. He rapidly rose to the highest professional distinction, and his long connection with the County of Antrim Infirmary, of which he was consulting physician and surgeon superintendent, brought him into contact with eminent professional brethren, who, recognising his great ability, placed him at their head. He had a large and lucrative private practice, not only in his own immediate neighbourhood, but throughout the province of Ulster, and, indeed, throughout all Ireland. In almost every branch of treatment he was equally proficient, and in special cases of ailment he was constantly in his consulting-rooms, which were oftentimes crowded by patients from every part of the North of Ireland. Dr. Thompson was an M.D. of the University of Edinburgh and a Fellow of the Royal College of Surgeons of Ireland. All through his career Dr. Thompson entered but little into what is known as public life. His great field was the consulting-room. He never interfered in matters political, even in the most exciting times. It may be remembered that a short time ago, when walking through his own house, he sprained his ankle, which up to the time of his death gave him much trouble. The difficulty he experienced in walking was very apparent, and few, indeed, could pass the clever old gentlemen in the street without sympathising with him in the strongest manner. By the removal of William Thompson, the medical profession has sustained a loss of which every member who knew him is thoroughly conscious. The vacancy which has been

created will not be easily filled. He has left behind him a great name for his profession, and an honourable one as a gentleman, and for many years to come he will be remembered with gratitude and respect in the North of Ireland.

Notices to Correspondents.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE SHAM CERTIFICATE SYSTEM.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—You deserve the thanks of regularly educated members of the profession for your article on the above in your issue of Sept. 6th. The apprentices of apothecaries have for years been in the habit of presenting fabricated certificates both at the Irish Hall and elsewhere without the slightest effort being made to put down the nefarious system. Let anybody but take up the Dublin papers and he will there find apothecaries advertising for apprentices, to whom they pretend to allow time for attending lectures, hospital, &c. Now, as time for all these would simply occupy the student's entire day, and as these gentlemen only give about two hours daily, it necessarily follows that their pupils could not have attended the lectures and hospitals which the fabricated certificates assert that they did attend. Unless some efficient steps should be taken at an early date, I will bring the matter before the Medical Council at its next session, and I shall not hesitate to refer to names in the memorial which I propose to put in.

Yours faithfully,

THOMAS LAFFAN.

M. R. (Exeter).—You are misinformed. No such rule was ever passed by a majority; an attempt, however, was made about twelve months ago to reorganise the Society, but without success. The discontented faction have since then resolved to form themselves into a distinct association, and carry out the programme with which they sought to enter on office in the parent society. They are not likely to do very much to justify their secession.

CONSULTATION ETIQUETTE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I see in your issue of Sept. 13 what purports to be a reply from Dr. Adrian to my letter. Dr. Adrian says there was both a written and verbal explanation given by him. I beg to remind Dr. Adrian that the only letter I ever received from him was the one in which he mentioned having visited my patient and asking me to meet him next day. This letter did not contain one word of explanation, or give any reason why he visited in my absence. The only explanation I received from him was a verbal one after he had received my letter addressed to him complaining of his unprofessional conduct, and that explanation had reference only to the visit paid the previous evening. Dr. Adrian's explanation, such as it was, was unsatisfactory, and I told him so on the occasion. I remarked at the time that I would take it for what it was worth, to avoid unpleasantness.

I am, Sir, yours faithfully,

RICHARD CRONIN.

P.S.—I should add that my letter to the *Medical Press* was written before said explanation.—R. C.
Sept. 18th, 1882.

MR. E. GOODWIN (Maldstone).—The gentleman concerned is abroad, but will return shortly, when the contents of your note will be communicated.

SURGEON-GENERAL CRAWFORD.—The accession of this gentleman to the control of the Army Medical Department in Egypt appears to have given universal satisfaction to the combative forces. In speaking of the results already achieved, the *Broad Arrow* remarks that "the new Director-General and his excellent Lieutenant at the head of the medical branch have already furnished ample guarantees of their special fitness for the responsible posts to which they have succeeded, and we may hope that the long period of disquiet to which the department has been subjected will now, under the direction of abler hands, be followed by a wise and just administration which will erase many bitter memories."

LEAVE OF ABSENCE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you be kind enough to inform me whether I can leave the dispensary district of which I am medical officer for a week or so on vacation by paying a substitute myself and without applying to the dispensary committee for leave of absence? Is it sufficient to notify the fact of my leaving to the secretary or chairman of the committee?

Truly yours,

RUSKINS.

[No medical officer can take an hour's leave without permission of his committee. Permission given by the hon. sec. is practically sufficient; but in that case the secretary takes the whole responsibility of acting for his committee.—ED.]

DR. A. T. THOMSON (Glasgow).—The case is marked for insertion in our next number.

A SUBURBAN VACCINATOR.—No death from small-pox was registered amongst the population of four millions in London last week. Two cases were reported in outlying suburbs; the metropolis may therefore be considered in a most singularly healthy state, not only on this account, but from an absence of any other zymotic disease.

DR. WILSON.—The demand for "particulars" is not unusual, and

should not be resisted. A readiness to give the details asked for would probably disarm your patient in future, and give him the impression, which he seems now to need, that he is dealing with an honourable man.

THE LATE DR. THOMPSON, OF LISBURN.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It was with extreme regret I read in your Obituary column of Wednesday last the death (killed accidentally) of Dr. Thompson, of Lisburn, than whom it is not too much to say a more eminent and generally respected practitioner did not exist in Ireland. For many years surgeon to the Co. Antrim Infirmary, many of his operations rivalled in their successful daring those of the most eminent surgeons in all parts of the world. I believe I am correct in saying that Dr. Thompson was the first man who successfully performed ovariotomy in Ireland; he was of a modest, retiring disposition, and never published a line, consequently is unknown outside his own district, where his name will long remain a household word for skill and kindness. I shall not soon forget how he stood by me in the early part of my career when a course I had adopted was questioned, but circumstances proved that we were in the right, and I owe him undying gratitude. Peace to his ashes! He will long be remembered and regretted in all the country side.

Yours, &c.,

MOIRA.

Peckham, Surrey.

THE OBSTETRICAL SOCIETY OF LONDON.—The first meeting of the winter session of this Society will be held this evening (Wednesday), at 8 o'clock, when Dr. Hopkins Walters will bring forward a "Case of Post-partum Avulsion of the Uterus, &c., followed by recovery."—Dr. Champneys, one "On an Obliquely Contracted Pelvis of Unilateral Synostosis."—Dr. Gervis, one "On a Case of Transverse Septum in the Vagina."—Dr. Matthews Duncan, one "On a Case of so-called Imperforate Hymen."—Specimens will be shown.

Vacancies.

Burton-on-Trent Infirmary.—House Surgeon. Salary, £130. Applications to be sent to the Hon. Sec. on or before Oct. 16th.
Granard Union, Finnea Dispensary District.—Medical Officer. Salary, £100, and £14 as Medical Officer of Health. Election, Oct. 14th.
Ongar Union, Essex.—Medical Officer of Health. Salary, £60. Applications to be addressed to the Clerk on or before Oct. 9th.
Owens College, Manchester.—Junior Demonstratorship of Anatomy. Salary, £125. Applications to be addressed to the Senate, under cover to the Registrar, not later than Oct. 9th.
Seamen's Hospital (late Dreadnought), Greenwich, S.E.—Resident House Surgeon. Salary, £50, with board, &c. Applications to be sent to the secretary on or before Oct. 7th.
Torbay Hospital and Provident Dispensary, Torquay.—Senior House Surgeon and Senior Provident Medical Officer. Salary, £100. Applications to be addressed to the Hon. Sec. not later than Oct. 16th.
Wokingham Union.—Medical Officer. Salary, £90 for the Wokingham District, and £30 for the Workhouse. Applications to be sent to the Clerk to the Guardians not later than Oct. 9th.

Appointments.

CREW, W. T., F.R.C.S. Eng., L.R.C.P. Lond., Assistant Medical Officer to the Brownlow Hill Workhouse, Liverpool.
DUMAT, H. A., M.B., C.M. Ed., House Surgeon to the Weston-super-Mare Hospital.
EVANS, W., L.R.C.P. Ed., M.R.C.S. Medical Officer of Health for the Anglesey and Holyhead Rural, and Beaumaris and Holyhead Urban, Sanitary Districts.
FARNELL, H. D., M.B.C.S., Medical Officer to the Workhouse of the Eastbourne Union.
LOW, A. B., M.B., M.Ch. Ed., Medical Officer for the Workhouse, Sunderland Union.
MCCLURE, H., M.D., M.Ch. Q.U.I., Medical Officer for the Queen Camel District of the Wincanton Union.
RAND, R. F., M.B., C.M. Ed., House Surgeon to the Oldham Infirmary.
RICHARDSON, W., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer to the Workhouse, Reading Union.
WOODCOCK, R. F., L.R.C.P.L., M.R.C.S. Surgeon to the Police of the Borough of Wigan.

Births.

BROWNIGG.—Sept. 25th, at Hill House, Gravesend, the wife of J. Annealey Brownrigg, M.A., M.D., of a son.
CUMMINS.—Sept. 27th, at Kingstown, the wife of Hy. Royce Cummins, L.K.Q.C.P.I., L.R.C.S.I., of a son.
DOUGLAS.—Sept. 28th, at Avenue House, Leamington, the wife of W. Douglas, M.D., of a son.
ROBERTS.—Sept. 26th, at 42 Upper Rathmines, Dub'ln, the wife of Dr. Browne Roberts, of a son.

Marriages.

WOOD—GOULSTON.—Sept. 27th, at Holy Trinity, Newington, S.E., Arthur George Wood, M.R.C.S., L.R.C.P., to Ada Jane, daughter of Edmund Goulston, of 37 Trinity Square, London, S.E.

Deaths.

BAIN.—Sept. 21st, at Fulham Park Gardens, London, James Bain, M.D., Surgeon-Major H.M. Bombay Army (retired).
CLOVER.—Sept. 27th, at 3 Cavendish Place, Cavendish Square, London, Joseph T. Clover, F.R.C.S.
FURLONG.—Sept. 22nd, at Streamville, co. Wexford, Andrew Furlong, M.R.C.S. Eng., aged 78.
ROGERS.—Sept. 21st, at Bedford, Charles J. Rogers, Deputy Surgeon-General, Indian Medical Department, aged 59.

ON THE METHODS OF DIAGNOSIS IN DISEASES OF THE NERVOUS SYSTEM.

By E. C. SEGUIN, M.D.,

Clinical Professor of Diseases of the Nervous System in the College of Physicians and Surgeons, New York.

LECTURE I.—(Concluded.)

THE movements of the legs and feet in walking have been the subject of much study. Some observers have endeavoured to record the peculiarities of gait by means of giant sheets of papers so prepared that when a patient walks upon them imprints of his footsteps will be left. Such tests require considerable expenditure of time, and hence I would ask you to learn to judge of the gait of a patient by inspection and by the sense of hearing.

In the hemiplegic gait the foot is turned in, the heel raised, and the patient brings the extremity forward with a swinging, semicircular movement; he cannot bend the knee properly. This is what the French call the sickle walk. As the foot is brought forward, the outer portion of the sole of the shoe scrapes upon the floor. Hence it is that these patients first wear out the soles of their shoes upon the outer side. As a part of the hemiplegic gait should be noted the drooping shoulder of the affected side.

A characteristic walk is the ataxic. In this the leg is well raised, and the patient overdoes the extension and abduction movements of the step, bringing the foot down, heel first, in a jerking manner. A good method of testing co-ordination of the legs is by driving a pin into the toe of the patient's boot, and requesting him, while seated, to approximate the head of that pin to the head of another which you hold above it. If there be ataxia, the foot will oscillate in this movement, as the finger does in the nose test. In the recumbent posture there is a more classical test of ataxia. Covering the patient's eyes, we

bid him put his right heel upon his left patella. If he be ataxic, the heel wanders about in a vain attempt to hit the mark.

Another peculiar walk, which is of considerable frequency, is the paraplegic, the walk of partial paralysis. In chronic transverse myelitis the patient walks with a scuffling movement, dragging his toes upon the floor.

By closing your eyes and listening to the walk of two patients, one ataxic and the other paraplegic, you can tell them apart easily. The former makes a loud stamping sound with his heels; the latter scrapes the floor with his feet.

An important walk is the tetanoid, which I first described in 1873. (a) The patient takes very small steps and turns the toes inward. The feet are approximated, and there is a tendency to crossing of the legs from overaction of the adductors. The legs are rigid and the feet drag. You will find this in many children, occasionally in adults. This walk is believed to indicate primary or secondary sclerosis of the lateral columns, or want of development of the same parts.

In hysterical hemiplegia the walk is peculiar. A woman may seem to have complete paralysis of the arm and partial paralysis of one leg. In walking she moves the leg in the proper vertical line; there is no sickle movement; the foot is carried carefully and squarely over the ground, and is dragged. Dr. R. B. Todd, (b) of London, who was one of the most acute and skilful students of nervous diseases thirty years ago, first described this walk.

The walk of patients with cerebellar disease is usually badly denominated in the books. It is spoken of as ataxic, but there is nothing ataxic about it. If you were to test a patient with cerebellar disease as you would one with ataxia, by requesting him to shut his eyes and put the end of his forefinger upon the end of his nose, &c., he would have no difficulty in doing it. The walk of cerebellar disease is inco-ordinate, though not ataxic. It is

(a) "Description of a Peculiar Paraplegiform Affection." *Archives of Scientific and Practical Medicine*, No. 2. New York, February, 1873.
(b) "Clinical Lectures on Paralysis," &c. London, 1854, p. 187.

more like the inco-ordination of intoxication, or, as the French writers call it, *titubating*. The patient tries to extend his base of support by separating his feet, and his body oscillates from side to side. If the feet be bare, the patient's toes will be seen working abnormally, and apparently digging into the carpet. Nothnagel (c) has written the best account of the cerebellar walk.

I will add a few words about reflexes. These are tested usually by pinching, burning, or tickling the soles of the feet and other parts of the body. The tendinous reflexes are of more recent discovery. We determine their existence or non-existence by tapping upon the tendons with the finger, as in percussion. Then, there are internal or visceral reflexes, such as those of the bladder resulting from the organ being filled with urine, those of the larynx, and so on. In most of our examinations we test the tendinous reflexes. The tendon-reflex can be tested anywhere that a tendon can be got at. Upon the leg you can tap the tendo Achillis. The most commonly used and most convenient place of testing the tendon-reflex is at the knee. If we tap upon the hamstring tendons we get a movement backward. The tendon of the quadriceps extensor femoris, or ligamentum patellæ is always an object of investigation, and striking it causes a partial extension of the leg. In certain spinal diseases no reflex movement is there present; in other conditions of the cord there is increased reflex at the knee. The best way of judging this is to use at first a minimum amount of force in tapping the tendon, increasing it as necessary to develop the reflex movement. Dr. Gray, of Brooklyn, made some interesting experiments three years ago upon some of the students of the Long Island Hospital Medical College as to the normal tendon-reflex at the knee. He found it absent in two or three individuals out of a hundred healthy subjects; and I have seen similar exceptions.

Disorders of sensibility.—Here we come in contact with the consciousness of the patient—the ego of the patient, and we are to a certain extent at his mercy. In children this part of the diagnosis is limited to a very great degree on account of their inferior intelligence. For example, the sense of sight cannot be fully tested in these little patients, and when testing common sensibility we have to pinch and tickle them, and make use of other coarse tests. The special examination of the eyes and ears I will pass over for the present.

We will now consider the perception and localisation of simple contact such as produced by the finger or a feather. The patient's eyes being closed, we touch him slightly in different parts, and ask him if he feels, and where he feels the contact.

The question of "muscular sense" is an involved one. Some believe that the muscles have no proper sensibility, and that we know our muscular movements by psychic estimation of the force employed, yet there are some persons who cannot feel a tap or prick upon the skin of the leg, yet will feel firm pressure made upon the calf. There have been instruments devised for determining the amount of weight in grammes which a patient can distinguish. We test sensibility to pain in various ways. The use of the hot iron and matches is objectionable. We are not allowed, in an examination, to adopt such meteors as will result in scars. A faradic wire brush is harmless, produces no scar, and is really more painful than cutting or burning, as I have repeatedly seen; and a clean, sharp needle is not objectionable.

The brothers Weber, of Leipzig, gave us forty years ago a form of æsthesiometer, which is much like a shoemaker's rule, with one end stationary.

Another form of æsthesiometer is made like a compass, with or without a vernier. All æsthesiometers should have dull points. Dr. Birdsall has devised an improvement upon the former instrument. It consists in the attachment of a point at one end of the instrument, so that a patient

can be pricked at will. We know from Weber's researches the distance at which two points of the æsthesiometer can be distinguished on all the parts of the body. The following are some of the more important according to Valentin: (a)

	Millimetres.
At the tip of the tongue	1.00
" palmar surface of tips of fingers ...	1.50
" " " second phalanges ...	3.24
" " " first phalanges ...	3.44
" dorsum of the tongue ...	5.22
" dorsal surface of fingers ...	8.12
" cheek	9.46
" back of hand	14.50
" skin of throat	17.27
" dorsum of foot	26.10
" front of sternum	33.07
" middle of back	50.43

In estimating pathological conditions I am in the habit of making considerable allowance for normal variations. The points are to be applied to the surface of the skin simultaneously. This requires a certain degree of expertness on the part of an operator, and in order that the translation of the impressions be correct, some degree of intelligence on the part of the patient is required. In testing the tongue, the patient is to indicate the answer by holding up one or two fingers. With the thumb and forefinger you can increase or decrease the distance between the points.

One word about motor and sensory tests with a battery. For this purpose, either a faradic or galvanic current can be used. We use both currents for testing the condition of the connection between the nervous centres and the peripheral organs. I can only formulate a general law, and it is this: that in cases of disease of the brain in which the spinal cord and nerves continue to act upon the muscles, even though the will has no influence over them, the electrical reactions are preserved. In cases of certain spinal lesions, especially in transverse lesions, the same law holds true.

The affections of the spinal cord which destroy or involve the grey matter of the anterior horns will be accompanied, within a week or two weeks, by a loss of reaction in the paralysed muscles and their nerves; whereas, with a lesion of the spinal cord which leaves a certain part of the grey matter below the lesion uninjured, even though it be but half-an-inch, we will get reactions in those muscles connected with the healthy part of the cord. In cases of injury to the spinal cord very low down, which destroy the lumbar enlargement, the muscles of the paralysed legs undergo atrophy and lose their reaction to faradism. With a destructive lesion of the cervical enlargement, the same occurs in the hand and arm. The law may be stated in the following words: Destructive lesions of the grey matter of the cord abolish faradic reaction in the associated or dependent muscles. The same law is applicable to so called peripheral paralysis, in which the nerve-trunk has been divided or crushed. Hence, you see there is nothing pathognomonic determined by means of the electrical test; it is of conditional value.

I would like to say something about the use of the ophthalmoscope. I consider its use of great importance in the study of nervous diseases; yet I feel that too much has recently been claimed for it. I would urge all of you to learn to use it and to recognise the healthy fundus. By so doing you will get negative information; and you should also learn to recognise atrophy of the optic nerve, neuro-retinitis, or choked disc, and the retinitis of Bright's disease. These signs are positive and valuable indications of disease. It has been claimed that by the ophthalmoscope we can

(c) "Topische Diagnostik der Gehirn-Krankheiten." Berlin, 1879. Pp. 89-91.

(a) For a complete table in lines (about 2 mm.) consult Flint's Text-Book of Physiology, p. 763. New York, 1881.

determine the condition of the intra-cranial circulation, judging of this by the state of the retinal vessels. This I do not believe to be possible, partly because of the great normal variation in the circulation at the bottom of the eye; partly because of the varying appearances of the vessels, according to the condition of the refraction of the eye; and lastly, because it is not at all certain that there is any correspondence between the retinal and cerebral circulations. I am supported in these statements by leading oculists, who consider it a delicate task to decide whether a retina be hyperemic or anæmic.

ON THE TREATMENT OF FRACTURES OF THE PATELLA.

By HUGH OWEN THOMAS, M.R.C.S.

FROM an early period until now surgical records inform us that fractures of the patella have been supposed to require exceptional treatment.

Surgeons have insisted on the importance of certain details as necessary to success; some laying great stress upon the position of the limb during treatment, others on the careful adaptation of the fractured parts, while all deplore the uncertainty of useful recovery, the patient having a loss of power, or lessened radius of action, of the knee-joint. Malgaigne's method of actual fixation of the separated segments has lately been in frequent requisition. His mode, however, has generally been modified, his steel hooks having been replaced by wire suture, and thus surgeons who think that close adaptation of the segments is the most important part of the treatment have, in one or other of these methods, a certain means of accomplishing their object. For many years I also shared the belief that this close adaptation was essential to success, and that, as an adjunct, the position of the limb greatly favoured a perfect result. What is wanted is a method of treatment which renders nearly certain a recovery free from defect in function. During the many opportunities I have had of treating these accidents, I have gradually attained the conviction that neither position nor nicety of adaptation during the treatment of fractures of the patella is in any way essential to a cure, free from defect in function or power.

Experience has clearly taught me that there are four points hitherto overlooked, which, if attended to, give so high a percentage of success as to show failure to be a very rare occurrence. The first is "time;" the second, non-interference with the circulation round the patella; third, that no strain in the direction of flexion be allowed during treatment; and, lastly, the temporary ankylosis produced by the treatment should be allowed to become corrected spontaneously.

In regard to time. I now know that it is necessary to postpone, uninterruptedly, genuflexion until a period of eight or nine months has elapsed. This is the time which observation has shown me to be a safe date at which to suspend control. The nine months of surgical control may be considered as divided into three periods. The first, representing the removal of effused fluid; the second, during which union is progressing; the third being spent in the consolidation of the united medium, when it becomes free from inflammation—i.e., healthy. At the end of this time the connection between the previously separated segments of patella, whether bony or ligamentous, will stand, if sound, any habitual strain; and whether the two segments have been in close apposition or a perceptible distance apart, is merely important from the point of view of appearance. Hitherto, a period of ten weeks, first prescribed by Heister, has generally been deemed sufficient for recovery, and then the patient is allowed the uncontrolled use of his knee-joint. I know from observation that cases have recovered in six weeks free from defect, and that independent of the surgeon's art. On the other hand, there are to be met with a great

number of these injuries which, after the usual limited period of surgical treatment, exhibit a permanent defect of function annoying both to the surgeon and to the patient. That the fracture should fail to recover, unless controlled for this long period, is not surprising, when we consider the enormous strain to which the medium connecting the segments of the patella must be subjected as soon as the ordinary use of the limb is attempted, this strain being much greater than that to which a normal patella is subjected. To withstand this tension, the connection must be sound—free from all trace of inflammatory congestion. This is the secret of success—the production of a permanently useful limb.

The mode of repair of fractures of the patella is simply that which takes place in fractures of other bones. When consolidation has not occurred, the connecting medium and surfaces of the fracture are of low vitality, and the development into true bone is delayed or arrested. In cases of delayed union, consolidation may finally be completed without special direct interference, while non-union, total arrest of development, if not specially treated, will become permanent. The adventitious matter and its points of attachment being in a condition of stasis, may at times be equal to the wear and strain of use—this is true non-union. But the condition of delayed union or unsoundness is often erroneously termed non-union. True or healthy non-union is equal to the resistance of much strain, while delayed union is rapidly impaired by use, evidenced by gradual increase of deformity, whether it be in a fractured patella, thigh, or leg. Hence the necessity of spending so much time in the treatment of each case, in order that, when the surgeon removes all restraint from the limb, he may feel convinced that bony or true non-union must have been arrived at. It will not matter in fractures of the patella which of these may exist at the time of convalescence. One of the causes of failure in times past has arisen by not allowing a sufficient time to elapse, so as to place beyond doubt the soundness of the connection of the fragments. That this prolongation of treatment in some cases may not be required, I admit. But how is the surgeon to gain this knowledge? His reputation and the patient's comfort may irreparably suffer if he errs. During the treatment of fractures of the patella we cannot learn much by manipulation regarding its repair as we readily can in other fractures of bones, where indications for suspending or prolonging treatment are obtained by exercising strains of the bone in various directions.

In fractures of the patella, use is the only test, and, should it show signs of failure under this test, the treatment must be re-continued, but still as a result of this trial, the deformity becomes more evident than would have resulted had more patience been exhibited. And although the occurrence of deformity is not fatal to usefulness of the limb, still the lesser the deformity the more creditable does the management of the case appear.

Another cause of failure has been the interference, by circular compression, with the circulation around the patella during the first month, and thus the vitality of the part is so depressed, the process of repair is delayed proportionately to the force of such compression.

It is best to allow subcutaneous swelling to subside slowly and spontaneously, while the limb is also controlled to arrest all motion of the knee-joint. This can be done easily by using an appliance which permits the firm application of stays of bandage above and below the knee-joint. And when the surgeon decides to release his patient from all control, the temporary stiffness should be allowed to wear off, supplemented by exercise at the will of the patient only. No attempts at forced flexion by the surgeon, as such ill-judged attempts at increasing the radius of the knee-joint action subject the part injured to a strain which it never was subjected to during its normal state, if we except the force which sometimes causes these fractures. The period required to regain full radius of action varies from three months to two

years. These are my essentials of treatment, and, when adhered to, they permit of an excellent cure, without any defect in function, whilst the patient need not be confined to his bed a day, provided the fracture is not accompanied by very painful effusion.

(To be continued.)

ECTROTIC TREATMENT OF VARIOLES IN SMALL-POX—CAUTERISATION BY CARBOLIC ACID—WITH MORBID ANATOMY AND PATHOLOGY OF THE VARIOLES, AND GENERAL LOCAL TREATMENT. (a)

By MONTAGUE D. MAKUNA, L.R.C.P. Lond.,
M.R.C.S.,

Late Medical Superintendent of the Fulham Small-pox Hospital.

THROUGHOUT the epidemics of small-pox from 1876 to 1880 I have had sufficient opportunities to study every phase of the disease both by the bedside and in the post-mortem room, and I lay before the profession my experience in the local treatment of varioles in 1,600 acute, and about 1,000 convalescent cases. During this time I have tried various local applications to judge of the merits claimed for them by different observers, to alleviate suffering and pain, to abort the varioles, and prevent disfigurement. The principal object of the ectrotic plan of treatment is to prevent or diminish pitting in those cases where it would occur, and it can be gained only when we abort the varioles by diminishing or preventing suppuration, and thereby the disintegration of the structures of the skin involved. It is not required in those cases where the disease is modified, chiefly by vaccination, and where the victims mock at the disease and are led to believe in the true nature of the complaint with great difficulty, as in variola varicelloides, and v. discreta.

I shall first give the morbid anatomy and pathology of the varioles, followed by my plan of the cauterisation of the varioles by carbolie acid, and general local treatment.

Morbid Anatomy and Pathology of the Varioles.—In describing the morbid anatomy of the varioles I shall take the description given by Dr. Fox in his treatise on "Skin Diseases," and that of Dr. Klein in "Variola Bovina," as my guides.

Erythema Variolosa is seen in a few cases during the initial stage accompanied with high fever, and disappears with the rising of the papules. During the papular stage there is thickening of the epidermis over a definite area at the seat of lesion. The cells of the rete Malpighii with their nuclei increase in size. The subjacent papillæ of the corium are enlarged by the germination of the endothelium of the capillary vessels. The lymphatic canaliculi are enlarged and rendered more distinct. The lining cells of these channels are increased in size, and in more vascular parts these channels are filled with migratory corpuscles. This gives rise very frequently to a hard or shotty feel under the skin over the papules. These canaliculi of the lymphatics are filled with granular material in a day or two. In about three days' time vesicular stage commences. When the vesicle forms, a layer of elongated cells is observed beneath the horny layer, and these pass without interruption into the cells of the rete Malpighii. Under this layer is a network, forming lacunæ, and enclosing lymph. It is situated nearer the horny layer than the corium, and forms the proper vesicle. Dr. Klein states that the enlarged cells of the rete Malpighii dilate, and form vesicular cavities, between them septa are seen, composed of flattened and scaly cells, extending from the horny layer to the inter-papillary processes. The vesicle is therefore chambered

into lacunæ, containing granular pus-corpuscles, red blood corpuscles, and small highly refractive granules, usually in masses of various sizes. The granules are small, pale, and indistinct, sometimes large and shining. We also see some transparent spheroidal bodies, and in some sections small colonies of micrococci during the pustular stage, which commences about the fifth day of the eruption. During this stage, the exudation corpuscles and pus-cells increase in number in the lacunæ, and infiltrate the tissues to a much greater extent. When a pustule is fully formed (which is about the eighth or the tenth day of the eruption), the network formed by the elongated and stretched-out cells of the rete Malpighii spreads deeper and deeper towards the corium, whilst its lacunæ are more and more filled with pus-cells, exudation corpuscles and other contents of the vesicles, and as it advances in maturation the septi forming the walls of the lacunæ give way, making an irregular honey-comb. The umbilication of the varioles takes place about the fourth or fifth day. It is caused, as far as I have observed, by the flattening of the superficial and central lacunæ through the evaporation of their watery contents which are first to develop. The development of the varioles is more or less accompanied with hyperæmia, tension, and œdema of the surrounding and subcutaneous structures. Occasionally, and in severe cases, bullies are formed, especially over the legs, feet, forearms, and hands. They are superficial, and sometimes overtop the varioles. The petechiæ and hæmorrhagic blotches, observed especially on the lower part of the abdomen, and the flexions of the thighs and arms in variola maligna are caused by the exudation of the bloody serum through the capillary vessels, as the diminished specific gravity of the serum, and the deteriorated condition of the blood allows of such a process. In variola maligna with extensive hæmorrhagic patches, varioles are very slow to advance, and sparsely distributed over the surface of the body. In the confluent variety of the malignant type, the varioles present an appearance of sago paste, and they undergo rapid ulceration. The variety described by Dr. Curschman, as variola hæmorrhagica pustulosa, where hæmorrhages take place in the varioles in later stages, does not in my opinion, bear out any distinct pathological significance. From my observations I have come to the conclusion that these hæmorrhages are merely mechanical, as recorded in my Report of the Fulham Small-pox Hospital for the year 1878. "Sometimes in later stages, and on account of partial apnoea, induced by lung complications, laryngeal eruption, or severe throat symptoms, hæmorrhages in the pustules, and oozing of blood from the mucous surfaces does take place. In these instances hæmorrhage is merely due to the engorgement or rupture of the capillary vessels, and caused by mechanical congestion."

I shall now pass on to the consideration of the different applications, recommended by several observers, which are useful at the various stages of the disease, stating my objections to the use of some of them. In judging of the results of a treatment, especially in the prevention of pitting in small-pox, different observers would observe them differently at different times. The confusion which arises when a plan of treatment is recommended by one and fails in the hands of others, can be explained by the fact that very often hasty conclusions are arrived at without giving time for nature to run its course. It is not right to pronounce an opinion within a few days' time of the convalescence, whether a case would be badly or slightly pitted or not pitted at all. The healthy tone of the skin is not restored for months, at any rate before six months in very many cases, and it is after the lapse of such a time that one can judge of the results of the treatment. Again, the success depends, to a certain extent, on the life a patient would lead after the attack of the disease, his age, occupation, and the exposures he would undergo; because these conditions tell on his

(a) Read before the Royal Medico-Chirurgical Society, 9th May, 1881.

constitution, tax his nervous energy and circulation, and influence his restoration to perfect health, consequently they would affect the healing and cicatrising processes of the wounds in the skin of his body.

I shall classify the treatment into four headings:—

1. General management and applications.
2. Ectrotics to prevent pitting.
3. Remedies used during the pustular stage to prevent further disintegration of the tissues.
4. Treatment during convalescence.

1. *General Management and Applications.*—In cases of *V. varicelloides* and discrete little or no local treatment is required, except cleanliness, evacuations of the contents of the pustules, when large and deeply seated, with broad-pointed suture needles, and frequent baths. In severe discrete, coherent and confluent cases, there is a good deal of the oedema of the face, especially over the eyelids, and in many cases over the distal parts of the upper and lower extremities, before the vesicular stage commences. The conjunctivæ are more or less inflamed, and the eyelids stick together with muco purulent discharges causing a good deal of discomfort and pain. I generally have the patient's face and extremities washed morning and evening with warm water and carbolic acid lotion, which eases pain and relieves itchy sensations arising from the tension of the skin. A drop of castor oil is dropped into the eye every night to prevent the eyelids sticking together, with great benefit. In severe cases warm fomentations every three or four hours are used; cotton wool and bandages might be used with advantage to relieve pain and oedema of the extremities. In children, gloves padded with cotton wool are useful to prevent them from scratching. In some cases, where there is a good deal of the hyperæmia of the skin of the face, with burning sensations and restlessness, I find the application of linamentum calcis of very great value. It acts as an emollient and sedative, easing the smarting and tingling of the skin, and thereby relieves inflammatory symptoms. It is recommended by Dr. Joseph Bell as an ectrotic, but as it exerts little or no influence on the contents of the varioles, and as it is not a germicide, I have not classed it as such.

2. *Ectrotics to Prevent Pitting.*—I shall now consider this important group of remedies, giving their therapeutical value and objections to the use of some of them. These remedies are used to abort the varioles and prevent the disintegration of the structures of the skin. We see from the morbid anatomy given above that we could attain such an object prior to the second or third day of the vesicular stage, and a day or two later we might be able to do some good. But when the pustular stage is reached it is useless, as the process of disintegration of the deeper structures of the skin has already caused a havoc, which no resources at the command of the science and art of medicine can ever restore. Again, we cannot use these agents at an earlier stage, as it is often impossible to pronounce an opinion as to the type of the disease before the vesicles make their appearance. It is here that many observers stumble over. They think from the general and other symptoms at the commencement of the disease that the case will turn out a severe one, and experiment with various applications; and were it subsequently to prove to be a mild confluent or a discrete one, he takes the credit of having modified the eruption. The conditions contra-indicated for the application of ectrotics are erysipelatosus inflammations, oedema of the skin, especially the face, low typhoid symptoms which are the precursors of the malignant type, petechiæ and blotches on the skin. Under these conditions our efforts ought to be directed more to the saving of life than to prevent disfigurement.

Cauterisation by Carbolic Acid is the ectrotic plan of treatment to which I draw special attention in this paper. (Since the reading of this paper I have seen Dr. Sansom's two cases treated by carbolic acid cauteri-

sation, and I was struck with the beneficial results. I have also read of the experiments of Dr. Sansom and Professor Lemaire in the treatment of varioles. When I followed out the plan of treatment, on a much more extensive scale, I had no knowledge of the work of Sansom and Lemaire.) It was suggested to my mind on reading the lecture of Dr. Peter Eade on "The Uses of Carbolic Acid," as reported in the *Lancet*, of June, 1878. He has used strong glycerine solutions of it for ulcers, sores, and wounds of various descriptions with success. It has been demonstrated that vaccine vesicles abort on the application of carbolic acid. Looking at it from a therapeutical point of view, I think it is eminently suited for the purpose. As Dr. Ringer remarks, it destroys the lowest forms of animal and vegetable life, and prevents fermentation and putrefaction; in fact, it is a disinfectant and an antiseptic. According to Sir Erasmus Wilson, it is a local anæsthetic, benumbing the surface of the skin, and it coagulates albumen. Professor Lister states that in wounds all the local inflammatory mischief and general febrile disturbance, due to irritating and poisoning influence on the blood, are avoided by the antiseptic treatment by carbolic acid. It is readily absorbed by the skin. It is certain in its action, and can be used in a concentrated form without the risk of injuring the surrounding parts or tissues to which it is applied. It is the only disinfectant that finds most favour with me, being the least objectionable of all, and I have used it most extensively, both medicinally and as a disinfectant; but I have not known a single case in my practice in which its toxic symptoms were developed. Its application is attended with little or no pain. The solution I use is made up of three parts of Calvert's crystallised carbolic acid (medicinal) and one part of glycerine. I shall now give the details of the operation. No sooner a case is brought to my knowledge, before the development of the vesicles, I watch their progress and determine the severity of the eruption and the type of the disease. If the eruption is confluent, without erysipelatosus inflammation and with little or no oedema, and the type of the disease benign—cases in which pitting is most marked—I select them for the operation. I get the face, hands, and other parts to be cauterised, properly washed with carbolic acid soap and warm water, and after wiping them dry, I apply olive oil over them, the previous evening. After a good night's rest, the parts are again washed and wiped dry in the morning. I take a fine camel's hair brush, dip it in the solution, of the strength given above, and drop it on the vesicles. Within two or three minutes they are cauterised, and present white scars on the surface of the skin. As soon as the cauterisation of a part is effected, olive oil is applied over it to neutralise its further action. The parts cauterised are again washed out within a few hours' time, when not the slightest disfigurement of the skin is observed. Now watch the results from day to day. In some cases these varioles are completely aborted, the epidermis falling off in scales; while the deeper structures at the seats of the lesion remain hardened papules, as in *horn-pock*, and undergo subsequent resolution. In other cases, the superficial pustulation is complete in about three days. The success of the operation depends principally on the selection of the cases. The next plan of treatment I adopt is cutting open the vesicles, and dabbing their surface with carbolic acid lotion (strength—1 to 60), and then powdering the surface with equal parts of oxide of zinc and starch, when there is a good deal of discharge; or applying castor oil and collodion when there is little or no discharge. I adopt this plan of treatment when a case is brought to my knowledge during the advanced vesicular stage and is running on to pustulation. If the vesicles are large, as they usually are, I cut their tops off with a pair of fine curved iris scissors used by ophthalmic surgeons. If they are small and few, I open them up from side to

side with a fine broad suture needle. These are the only two plans of the ectrotic treatment I have found of use after a prolonged experimentation of several other remedies. I shall now treat of several other plans of treatment recommended by different observers, some of which are highly objectionable, while others are impracticable.

(To be continued.)

THE TREATMENT OF THE SEVERER FORMS OF NEURALGIA AND MUSCULAR RHEUMATISM BY MEANS OF MASSAGE AND OF METHODICAL MUSCULAR EXERCISE. (a)

By Dr. J. SCHREIBER.

Translated from the *Deutsch Med. Zeitung*

By J. E. BURTON, L.R.C.P. Lond., M.R.C.S.,
Physician-Accoucheur to the Liverpool Lying-in Hospital.

GENTLEMEN,—If you take up the most recent treatises on neuralgia and muscular rheumatism you will find in the comprehensive works either no mention whatever of massage as a method of treatment, or its name barely mentioned. As far as I know, amongst modern authors, it is Benedikt alone, who freely and without prejudice has laid stress upon the powerful action of massage. In regard to surgical diseases, the employment of massage has obtained an entrance everywhere since Stromeyer and Volkmann appeared in favour of this method of treatment.

The obstinacy and painful character of neuralgia generally compel the attending physician to make use of the whole register of available methods of treatment one after the other, from mustard plasters to commence with, to attacks at the hands of the surgeon, from quinine to arsenic, from belladonna ointment and morphia injections to electricity and the actual cautery, from the simple diaphoretic to the energetic cold water cure.

When at last the endless array of means and medicaments has been exhausted, and the physician blindly brandishes his weapons before the malicious demon "Neuralgia," then is the despairing patient packed off to a climatic *Kurort*, in order that change of air may complete the miracle.

I have had, however, in my calling, opportunities of seeing that this "*Deus ex machina*" thus appealed to in time of utmost need fails to do his duty, and the patients as before retain their neuralgia, their muscular rheumatism.

When some years ago the reports about the powerful action of massage forced their way into publicity, I joyfully greeted them, and now, in an already considerable number of cases, I have had the satisfaction of achieving a surprising and durable success by the use of this method of treatment.

Permit me here to say emphatically that I have drawn my results not from mild cases of brief duration, but from the successful treatment (*Heilung*) of severe, inveterate cases of neuralgia and muscular rheumatism that have persisted for years, and that had been treated without good result by all the other methods.

The short space of time allotted to my address lays upon me the duty of touching upon the most important points only of this method of treatment.

From the circumstance that the pathological anatomy of neuralgia and muscular rheumatism is up to the present a *terra incognita*, the conclusion may *a priori* be drawn that all methods of treatment can be founded upon hypothesis only.

Concerning the changes in the sensitive nerve apparatus, we know as good as nothing.

These changes are inaccessible to the present therapeutic methods of research. To this hour such a darkness rules over the existence of neuralgia, that Erb considers all views that have taken a decided shape as to the nature of neuralgia to be premature, and Senator, in his

introduction to the "Diseases of the Apparatus of Motion," says:—

"Muscular rheumatism is a completely indefinable rubric that has to receive all those painful affections that have for their seat the muscles, or their neighbouring parts that cannot be otherwise classed; it may be said of it, as was said in that old grammatical rule—

"Those pains that can't be otherwise defined
All in the class called rheumatism you'll find.
(Schmerzen die man nicht definieren kann
Sieht man als rheumatismus an)."

Both diseases, however, neuralgia and muscular rheumatism besides the "unclearness" that shrouds them, the great painfulness and the functional disturbance that characterises them have this also in common, that they sometimes bid defiance to all the hitherto available methods of treatment.

What now is the physiological action of massage and methodical muscular movements?

It is a complicated one. Many factors come into play, quite as much as in electrical treatment.

We have mechanical, thermic, trophic, and, most probably, molecular influences at work. Accurate observations teach us that sometimes the thermic, sometimes the vaso-motor action is the predominant one. One of the most familiar examples is the mild neuralgia caused by cold, and dissipated by the action of warmth. If in such a case massage be employed in place of warmth, the neuralgia disappears more rapidly. In this case the action of massage would be principally thermic—a conception that corresponds to the ordinary physical laws, according to which moving force can be resolved into heat.

As muscles attacked by neuralgia seek to withdraw themselves from activity, this inactivity reacts upon the blood supply. It is shown by experiment that the blood-vessels of muscles at rest contract, whilst those of muscles in motion dilate. The lessened blood supply leads to diminished irritability of muscle. At the same time the chemical changes that go on in muscular tissue fall behind during inactivity, so that accumulation of effete material takes place, and this also serves to check muscular function.

Massage, in the same manner as muscular contraction, causes an increased blood supply, the blood-vessels dilate under the mechanical irritation, and the artificially-produced hyperæmia serves the purpose of carrying off effete material.

From what has been said, it will be clear that muscular movements, active as well as passive, assist the action of massage, and Metzger also has credited them with possessing a high value. For myself, I have no hesitation in claiming for them the lion's share of the success that follows the employment of massage.

We have, however, another factor to consider. If it is true that in some neuralgiæ the pain arises in part in consequence of the pressure of exudation within the nerve sheath, massage will have the effect of softening and pressing back the exudation into the lymph channels.

Berghmann's notion may be here mentioned—that through the mechanical action of massage the nerve becomes numbed, that it for the moment loses its sensibility, so that it gradually diminishes.

Whatever may be the explanation of the process, the fact remains that, by the energetic and long-continued employment of massage, combined with methodical muscular movements, a cure can be effected in those cases of neuralgia and muscular rheumatism in which all other methods of treatment have proved ineffectual.

I must, however, narrow the limits of this assertion to those cases of neuralgia in which large groups of muscles are affected, such as ischiatic and humeral neuralgia, and in which no complete intermissions from pain occur.

Neuralgiæ of the head and face, which attack groups of muscles, and only occur periodically, are certainly relieved by massage. The paroxysms are delayed or shortened, but recurrences are prevented only in the rarest cases. The explanation of this may be sought in

(a) An Address delivered before the Naturalists' Society of Salzburg section of Medicine).

the fact that the forehead, nose, and cheeks only permit a very limited use of the mechanical treatment, and that, in particular, the so-called muscle-tapping cannot be carried out over the above-mentioned localities.

It now remains to explain the mode of procedure as briefly as possible—more briefly, in fact, than the extent of the subject demands. There can be no doubt that the best way of learning the details of the treatment is by autopsy—actual observation; but as those who first employed it could not have learned in this way, it will be clear that personal observation is not indispensable. When the broad principles are once laid down, each physician must assimilate the details of the method for himself.

Metzger divides the manipulation into four divisions—

Gentle stroking.

Hard rubbing.

Kneading.

Knocking or tapping.

In neuralgia only the two last methods of manipulation are suitable, but to these should be added "pressure."

In what manner the individual fingers, the fist, or the knuckles are to be used each medical man will find out for himself if he only keeps in view the object of the treatment, and this is to thoroughly work up every structure affected by the neuralgia from the very bottom. During manipulation the locality operated on must be borne in mind, particularly the relation of the soft parts to bones. The latter must be dealt with carefully. The edges of bones are much more tender than muscles, and if too much force be employed on the part of the masseur injury to the bones may possibly occur. The manipulation should always commence with pressure; this should be followed by kneading, and this by knocking or tapping.

Pressure over certain parts, as, for example, the fossa supra-spinata scapulae, can scarcely be performed in any other way than by the tips of the stiffened index, middle and ring fingers. Pressure on the larger surface of the scapula is best effected by the firmly closed fist. If it be advisable to increase the force, it can be done by using the knuckles. If still more be desired, the metacarpophalangeal joints are to be employed.

Pressure must occasionally give place to pushing or digging down with the finger tips when the depth between groups of muscles is to be reached—for instance, on the inner side of the thigh, between the rectus internus and group of muscles springing from the os pubis. Here and there the thumb alone is to be brought into play.

In kneading, the word alone sufficiently indicates the method of manipulation. The part operated on is to be grasped between the thumbs on one side, and the four fingers on the other, and thoroughly worked between them. The thorough kneading of large groups of muscles is the most laborious part of the manipulation, and requires strong thumbs.

Tapping, or knocking, is less fatiguing. The edge of the flat hand is here employed, and the muscle should be struck transversely as well as longitudinally, care being taken to keep clear of the edges of bones. The force to be employed in the various parts of the process varies according to case and time—the more inveterate the morbid process, the more force must be employed in treatment. If the patient be too sensitive, the attendant must be the more cautious and gentle.

In almost all cases in which massage is employed, after one or other "sitting" extravasation of blood will appear in the parts operated on, and the patient will complain of pain in the discoloured spots. These must be left at rest until the colour again becomes normal.

With the exception of increase of tenderness, there bruises have no other injurious consequences, and it has even been noticed that, where this bruising has taken place, after some days the muscles act more freely and the neuralgic pains become less.

As regards the length of time during which the manipulation is to be employed on one and the same part of the

body, this must be decided by the stubbornness of the case and the resistance of the soft parts. As a rule, one to two minutes will suffice, so that it will take ten to twenty minutes to operate on ten different localities. Between the successive manipulations pauses for rest should intervene, as well in the interest of the patient as of the operator. It is important that at the commencement but little force should be used; this should be developed gradually as is thought necessary. Sudden and violent handling causes fear, and is not well borne. Massage may be carried out with the patient in any posture.

When, as in ischialgia, the horizontal posture is necessary, the patient should be placed on a hard non-elastic couch, as, if the couch be elastic, the strength of the operator is wasted. Ladies undergoing this treatment should wear a dress of light dark-coloured flannel, consisting of wide drawers and a suitable blouse. Linen does not do, as it glides too much under the hand, and fatigues the fingers of the operator.

The pain produced by the treatment is occasionally so great that the patient has not sufficient nerve to remain quiet. In such a case a third person is needed to hold the limbs.

After a "sitting" the patient is generally tired, sometimes exhausted. The temperature is raised $1\frac{1}{2}$ to $2\frac{1}{2}$ degrees, and the pulse accelerated. The pains set up by the massage subside after from 10 to 30 minutes. The patient desires rest, which should be permitted him. For this reason the active and passive muscular movements that are made use of should precede the massage. To prevent misunderstanding, it is well to state distinctly that the patient is in a better condition for the methodical movements after the manipulation than before, and that is only on account of the fatigue that it has been recommended to operate in the above mentioned order.

If pyrexia sets in, the massage must be stopped at once. It is well after massage has been employed, daily for about ten days, to give one or two days rest.

It is not necessary that the treatment should be always carried out on the uncovered skin; the parts intended for operation may also be oiled, and should then be covered with a woollen covering.

With regard to the methodical muscular movements, it may be said that all those muscles capable of being put into movement should be, and as at first this cannot always be done actively it should be done passively. A thorough acquaintance with the anatomy of the muscles, and of the pathological action of each individual suffering muscle will enable the physician to have a clear idea as to what muscles should be exercised.

For the active exercise of the various muscles many simple contrivances may be employed. They render the labour light, and economise time, as the patient can often use them himself. Many patients have not the courage themselves to make movements that are painful, but they will give themselves up to their medical attendant "auf Gnade und Ungnade," and will bear patiently the greatest pain, and this with an abandon and victim-like submission that is singular to contemplate, and that is heightened, if possible, by any sign of approaching improvement. The physician must not commit the error of giving up the treatment if after three or four weeks no improvement sets in; for two or three months he must not allow his diligence to slacken, nor his courage to fail. Gussenbauer reports cases that required two hours manipulation daily.

In proportion as the painfulness of the neuralgia or rheumatic processes diminishes, the muscular movements will be easier and more energetically performed; massage of the individual parts will require less time and labour; the active movements, in which the aid of the attendant will have been before required, will be by degrees performed independently.

It is well to state that experience has shown that no method of practising massage is universally successful. The same results are obtained in different ways. Whoever has practised massage for any length of time, will, encouraged by his success, follow ways of his own. Who-

ever will make use of this method of treatment must have a certain disposition thereto, a certain degree of manual dexterity, accurate knowledge of the anatomical relations of the structures operated on, great perseverance and patience, and then he will succeed without the advantage of learning from demonstrations. He must, however, have a clear conception of what he is aiming at, every movement of his hand must be guided by a consciousness of the end in view, and in order to enjoy the pleasures that attend success, he must enter upon the treatment of each individual case in confidence in his method of cure.

If once a case hitherto declared incurable has been restored to health future cases will be undertaken with the greater confidence.

May the words of the great surgeon Nussbaum which he addressed to the naturalists gathering at Munich be fulfilled :—

"Let it be the aim of the physician to win back to medical science those glittering triumphs that in many cases have been left to add lustre to the quack and the rubbing-women."

Clinical Records.

GLASGOW OPHTHALMIC INSTITUTION.

Detachment of Retina Cured by Operation.

By A. T. THOMSON, M.D.

Clinical Assistant.

IN my last communication I referred to another successful operation for the cure of detachment of the retina, I shall now give the details.

A. L., æt. 29, occupation stonemason, admitted into the Glasgow Ophthalmic Institution August 7th, 1882. He states that he always enjoyed good health and sight until the middle of January of the present year, when dimness of sight came on suddenly one morning; has been addicted to taking whisky in large excess; beyond this never suffered from any illness. On the margin of the left orbit on its temporal region is noticed a vertical cicatrix, caused by a piece of iron striking the part; this accident occurred three years ago, but he suffered from no failing of sight. He applied to two ophthalmic hospitals for relief, in both of which his case was pronounced incurable, from one of which he holds a card stating that he suffers from amblyopia potatorum and separation of the retina. He was indeed greatly addicted to drink, but as the other eye was never affected the diagnosis of amblyopia potatorum may be dismissed, the intention of the officers of those institutions seems to mean separation of the retina of an aggravated form; about the separation of the retina, however, there could be no mistake.

Ophthalmoscopic Examination.—Total blindness with general infiltration of the retina (of the left eye), but in addition there was one prominent central fold more elevated than the rest, consisting of a rag of the retina floating in the effusion.

Operation performed on the 9th August in the usual way, but instead of making the incision in the vertical meridian, it was done rather in the outer angle in the interval between the inferior and external recti muscles, the fluid was withdrawn by a puncture, and the lips of the wound brought together by means of a silk ligature, the eyes closed with dry lint and secured by an unmovable bandage.

August 13th.—Fourth day after operation, not the slightest reaction, ligature removed, and restoration of sight found highly satisfactory, can see faces, and also minute objects throughout the whole field.

25th.—Seventeenth day after operation. Vision restored to such an extent that he can see objects distinctly in every direction, can distinguish also the difference between a florin, a shilling, and a penny piece, reads No. 20 Jager, and can see to walk about when the right eye is closed. Ophthalmoscope shows still the small central floating detachment which has only slightly been reduced in size, but the rest of the infiltration has disappeared and the greater part of the fundus is perfectly visible.

In my last paper I referred to the advantage which Wolf's operation has over the Hirschberg-Graefe's method in respect

to its being performed in daylight, so that the case can be dealt with with more accuracy and precision; it has also the advantage which he has pointed out in his book on "Diseases and Injuries of the Eye," p. 282, arising from the superiority of the lance over Graefe's knife.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

THE TREATMENT OF CLUB-FOOT IN CHILDREN.—M. Jules Guérin, who, in spite of his great age (84), has lost none of the ardour and eloquence that has characterised his long professional career, entertained his colleagues at the Académie de Médecine on Wednesday last with a lengthy discussion on the treatment of club-foot in children. He criticised the methods employed by surgeons in different countries, who seemed to forget that club-foot is due to the retraction of certain muscles and tendons. Every kind of club-foot can be treated by the three following methods: tenotomy, manipulations, and apparatuses. According to the venerable professor there was no degree of club-foot in which osteotomy and tarsotomy could not be avoided. There could be no mistake in the fact that the total or partial excision of one or several bones of the tarsus puts the patient in a position far worse than the most pronounced deformity of the foot. Tarsotomy might, however, be practised in those deformities of the foot produced by articular or osseous affections, but not in the true club-foot. In concluding, M. Guérin insisted on repeating that tarsotomy for the treatment of congenital club foot was an operation that should be expunged from French surgery, in that it can be prevented and replaced by the means already mentioned—tenotomy, syndermotomy, manipulations, and orthopedic apparatuses. M. Gosselin replying, considered that the criticisms of M. Guérin were fully justified, but he could not accept them as applied to French surgeons, as he did not believe that such an operation was ever practised in France for such cases. M. Tillaux, quite in agreement with his colleagues, believed, nevertheless, that there should not be a wholesale attack made on the operation in question, as there were two cases very different, and should not be confounded—congenital club-foot and adult club-foot. In the first the means that M. Guérin proposed were amply sufficient as every surgeon has proved, and no recourse was had to osteotomy. But in the case of adult deformity such means had no control over the affection, and tarsotomy, which he considered an inoffensive and simple operation, might be practised with very good results.

TRANSFUSION OF BLOOD.—Dr. Roussel, of Geneva, has published two new cases of transfusion of blood that are well worth a perusal. The first was that of a young man who was employed in an abattoir in the neighbourhood of Paris who wounded himself in the thigh, severing the saphena vein and nipping the femoral artery. The hæmorrhage was frightful, and when a doctor was sent for he had lost five or six pints. The doctor on his arrival arrested the hæmorrhage and injected ether subcutaneously. The patient was in a profound syncope, with now and then great convulsive movements. As a last resource transfusion was proposed, and a telegram was sent to Dr. Roussel, who was stopping at Paris. On his arrival the state of the wounded man was very grave, thready intermittent pulse (180 to 190), with an earthy cadaveric face. Immediately six ounces of blood taken from a relative of the patient were injected. Immediately the man rallied and stated he felt

a great heat going up his arm and filling his chest. The pulse fell to 120. The rigor lasted about a quarter of an hour, and was succeeded by a reaction which brought the pulse up to 130. Five hours after the operation the pulse was at 96, and the patient expressed himself as much stronger, and partook freely of beef-tea. From that day to the 2nd July, that is to say, the eighteenth day after the operation, when the patient was able to go about as usual, convalescence was not once interrupted. The second case was more remarkable. A young lady, daughter of an English medical man, was brought in a dying condition from London to Geneva by her father, suffering from a very accentuated form of chlorosis. The father had tried every possible means, but all proved useless, and he decided on consulting Dr. Roussel with a view of having transfusion performed as a last resource. The patient was of a waxen paleness, the face was puffy, and there was general oedema. She could not be lifted up without fainting. The stomach bore no nourishment, save alcoholised milk. The respiration was superficial and insufficient; the *bruit de souffle* of anæmia could be clearly heard in the heart and carotids. Menstruation, which hitherto was very abundant, was now replaced by leucorrhœa. The patient was in a sort of stupor. On the 20th July five ounces of blood, taken from a robust peasant woman, were injected gently, which caused momentary dyspnoea and a slight cyanosis. The rigor was rather violent and followed by a reaction, which, however, was very slow in establishing itself. In spite of a little agitation the patient passed a good night, and in the morning the pulse—which had been previous to the operation very quick and steady—stood at 100. The appetite was almost voracious—she eats several times in the day; and during the whole succeeding week the improvement continued, and on the 10th August the recovery was complete. This young lady, since her return to England, has got married and enjoys perfect health. Dr. Roussel cites another case in which he transfused seven ounces of blood into a woman suffering from severe menorrhagia. The result was as brilliant as in the other cases.

Special.

THE MEDICAL SERVICES IN EGYPT,

WHATEVER differences exist between the several published accounts of the Army Medical Department sent from England for the Expedition to Egypt, there is complete accord among all as to the same department sent to the late seat of war with the Contingent from India. With regard to the first of these, we learn that bearer companies were sent out without transport of their own, and having thus to trust for transport to other branches of the service than their own, the result was that it was not supplied to them. The number of bearers is said to have been insufficient; nor does it appear that men of this description were drafted from regiments on the spot. The field hospitals were not only without sufficient transport, but the several articles of their *matériel* badly packed. It is even stated that some, at least of the medical officers, were made to embark without horses, and with only one servant as "man of all work." According to one correspondent—"When we succeeded in defeating the enemy at Maksanieh and in seizing the camp, we were indebted to the foresight and administrative efficiency of the Egyptians for having at our command much that was necessary for the treatment of our sick and wounded. If the truth must be told, we had literally nothing

ourselves, and when the Egyptian supplies were exhausted our medical staff was absolutely powerless. Medicines, we believe we are strictly correct in saying, were absolutely wanting. Ugly stories have been told of wounded men, whose dying agonies there was no means of alleviating by the administration of a single drop of laudanum. If, however, the transport was outrun in respect of food, it may not be surprising that medical accessories were deficient also, but it is now placed on record that even at Ismailia, beneath the shadow of the English transport ships, there was absolutely no provision for our sick and wounded. The most serious and painful operations in surgery were imperative, but, incredible though it may appear, there was no anæsthetics at hand to deaden the pain of the sufferers or to facilitate the work of the operators. In a word, the Medical Department absolutely and hopelessly broke down; or, to put it more correctly, perhaps, the department upon whose efficiency the members of the Medical Department were necessarily dependent."

Very different were the medical arrangements connected with the Indian portion of the forces. "On board the *Hydaspes*, and, we believe, on board of every troopship which sailed from India, the detachment conveyed was complete as a fighting unit. The *Hydaspes* had on board the horses, the mules, the ponies, the camp followers, the Commissariat, the stores, the war munitions, the medical officers and their medicaments, the cooks, the water-carriers, kits, stretchers—everything, in fact, required for the 'battle and the march.' Each vessel bringing her portion of the Indian contingent, landed it, perfect and independent as a warlike unit, so that five minutes after the ship was unloaded, the disembarked force could move anywhere in light marching order. Each detachment arriving was a little perfect armament, provided even to its cooking pots, and its kahars or ambulance-bearers." The very natural result was that as soon as the Indian troops got into action, the medical department worked efficiently and well, as it had been used to do, not only in the Mutiny campaign, but in many other campaigns, before and since that event. After the battle of Kassassin, an Indian medical officer visited the English portion of the force, and is said to have returned in amazement. "The Indians have been so habituated to war, that their arrangements are complete in matters of detail. 'Good heavens!' that Indian officer remarked to a correspondent, 'in case of a really severe series of engagements, the condition of the English wounded would have been no better than that at Waterloo, where the men lay unaccommodated for more than a week.' And what if an epidemic had broken out, a most probable contingency, where food was scarce and water fetid, the sun overpowering, a host of unwashed mortality penned up together, and medicines all carefully stowed away at the bottom of some transport on the bosom of Lake Timsah! It is an awful contemplation, and we can only thank God that the half-heartedness of the Arabs made our task so easy. Now, to what is this very deplorable state of affairs to be attributed? We have no hesitation in saying that wholly and solely due to our present organisation."

Another correspondent, after drawing a comparison between the two systems of hospital arrangement in the two branches of the force, thus refers to the Indian:—"Why," he asks, "is some such system impossible for white troops? Why should the men have been separated from their transport, their food, and their physio and medical comforts? It would be just as easy, surely, and much more safe, to divide a future expedition between the ships, and to give to each section their full share of stores and transport, instead of putting the men

into one ship, and what will feed and doctor and sustain them into another. Something like a confession of inferiority in campaigning still appears to have been made by our departments, since they sent an order out to the Indian Commissariat for a coolie corps under Punjabi officers for service in Egypt during the late campaign. No doubt the conditions of that campaign were peculiar, and suited the habitudes of our Indian regiments. But the difference—universally perceived and valued—between the well-supplied and mobile columns of the Eastern force, and the shiftless, starved, and ill-tended regiments from home points to an unscientific spot in our system. Nothing was contributed to the completeness of our triumph by the official 'arrangements' which kept the medicines and chloroform in the ships on Lake Timsah while the wounded groaned at Tel-el-Kebir, and the public will demand that this kind of service at least shall never be repeated."

To those of our readers who know the history of army hospitals an explanation of some at least of the above differences will instantly present itself; namely, what is called the "general" system in one case, and of failure; the "regimental" system in the other, and that of success. The further fact will also occur to those initiated that, during the Mutiny and in other Indian campaigns, a series of field hospitals could readily be extemporised when occasion arose, by a combination for the time being of certain portions of the regimental establishments. General hospitals in like manner were so organised as to supply the regimental with establishments when necessary, or to receive superfluous establishments from the latter.

A very important use of regimental hospitals on service as in times of peace is, or rather *was*, to enable the regimental surgeon to determine whether the illness of a particular man was of such a nature as to render his "admission" necessary; another equally important use, to enable him to return to the effective ranks of the regiment the men who recovered. To judge from the reports from Egypt, "the rule is to admit even the slightest cases" to the general hospital, because, no doubt, the medical officers unacquainted, as of necessity they are with individual men, are disinclined to assume the responsibility of "selecting" cases. As in many previous campaigns, so in the Egyptian; few men indeed, who were admitted into the general hospitals returned to the ranks during the campaign. In fact, it is devoutly to be wished that the contrast between the British and the Indian medical systems on active service may speedily lead to the utter abolition of the former, and re-adoption in the army of the "dual" system which has ever worked effectually and well, so long as scope and means of doing so were allowed to it.

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE ROCHELLE CONGRESS.

At the Congress of this Society recently held at Rochelle there was much important business transacted. The section devoted to medical science was remarkable for the large number of members who attended it. It was necessary, in order to consider all the papers, to have two meetings daily, each of two hours' duration.

FUNCTIONS OF THE PHRENIC NERVE.—The first paper was read for MM. Hénocque and Eloy, and was devoted to the consideration of the functions of the phrenic nerve and to contractions of the diaphragm. Experiments tried on animals showed that after having removed the roots of the phrenic nerve the immediate consequences were—1. Exten-

sive contraction for some moments of the inspiratory muscles; 2. The cessation of diaphragmatic contractions on the side operated upon; and 3. A very feeble respiratory movement of the thoracic wall on the same side, caused by the action of the inferior intercostal and the accessory elevators. Nervous regeneration has been observed in some cases at the end of a fortnight or more; respiration of the side operated upon recommenced afterwards, but was feeble in comparison with the healthy side; in some cases there resulted difficulty in phonation.

ANCIENT ARTIFICIAL LEGS.—It is well known that archæological documents relating to surgical prosthesis are very rare. M. Emile Rivière has, however, presented us with a very curious specimen. On a fragment of red Samian pottery found some years ago while excavating, there is a representation of a huntsman with a straight artificial leg; it was a kind of stump enlarged towards the upper extremity, on which the knee rested, cylindrical at the narrow part, and bifurcated at the inferior extremity.

TUMOURS OF THE UMBILICUS.—M. Nicaise then read some interesting observations on tumours of the umbilicus. The first case was that of a woman who died of uterine cancer, and suffered for some time from irreducible umbilical epiploic hernia. During the autopsy the surgeons were astonished to find that the hernia had become cancerous while the rest of the epiploon was quite healthy. This is an interesting example of *locus minoris resistentia*. The cancer localised itself on a point at which the anatomical structure was modified by the compression continually brought to bear upon it. The second case was that of a papillary tumour, which was also epithelial, and seemed to be superficial, but when they tried to raise it, it was found necessary to extend the dissection to the peritoneum, and even to divide the umbilical ring. The reunion was made by the aid of deep sutures comprehending the peritoneum, the sponeurosis, and the skin; these were made before drawing out the thread. M. Nicaise made the epiploon adhere to the posterior portion of the wound, and then applied the antiseptic method. Thus he obtained a very solid linear cicatrix.

TRICUSPID INSUFFICIENCY.—The experimental study of tricuspid insufficiency was the subject of a brilliant communication by M. François Franck, who devoted himself to the demonstration of the influence introduced into the circulation by the dilation of the heart and the valvular insufficiency which resulted. M. Franck also showed that the modification of function observed in many clinical cases could be reproduced by experimentation. Even the asystole can be overcome by producing at the beginning the pure tricuspid insufficiency in animals. This he determined by the aid of special valvulotomes. He also showed divers morbid phenomena in the veins of the heart and in respiration.

DOUBLE CONSCIENCE.—M. Ayam, who each year communicates to the medical world the actual condition of a patient who has the remarkable phenomenon of a double conscience, then informed the meeting of the progress of the malady in Félicité X. This woman, aged thirty-seven years, who has been ill for twenty-three years, has still, as before, two mental conditions, which M. Ayam terms the first and second states, the one normal the other abnormal: in one state she has no recollection of what passes while she is in the other. Originally the second condition was exceptional and rare; now it lasts from twenty to twenty-five days in each month; formerly she was very bright and gay when in the second condition; now she is very sad.

DENTAL CHANGES IN LOCOMOTOR ATAXY.—Dr. Th. David has observed in locomotor ataxy dental changes which he

thought were analogous to those of the hair and nails already mentioned in the description of this disease. In the case described by M. David these alterations consisted of a rapid mortification of the anterior wall of the crowns of nearly all the teeth. The altered substance became of the consistency of soft wood, and of a reddish colour. The enamel preserved its polish, but not its power of duration. Under these portions the pulp formed a fresh bed of secondary dentine, the bulbous cavity in most of the back teeth was filled, and therefore the atrophy bulb also. This fact, and the considerations which arise from it, tend to attribute once more the signification of a sensorial organ to the dental pulp; they establish also a pathological relation of the organs already united by one common epithelial origin.

DEATH-RATE IN GREECE.—Mr. Clon Stephanos made several researches into the death-rate in Greece during certain seasons, and has communicated to us the statistical results, which exactly correspond with the observations of Hippocrates on the same subject.

ACCIDENTAL IMPALEMENT.—M. Prunières reported a case of accidental impalement, and showed photographs of the different effects of the accident. A young man fell from a carriage on to a piece of railing, 1 metre long and 4 centimetres in diameter, which pierced his body in the lumbar region right through to the umbilicus, but without hurting the intestines. He lost all consciousness at first, but recovered without any inconvenience.

PREHISTORIC BONE INJURIES.—M. Prunières also showed several specimens of human bones pierced with arrows, supposed to have belonged to the Troglodytes, and therefore 10,000 years old. He also showed an iliac bone, in which a flint arrow was, so to speak, incrustated. The arrow had pierced the bone, and the wound in healing imprisoned it. He produced also vertebrae containing a flint arrow, and a heel-bone pierced by one, which was half-broken, no doubt, in the attempt to remove it. M. Prunières said, in answer to M. Verneuil, that he had seen specimens of rachitic bones, but they are extremely rare. M. E. Rivière succeeded in proving the existence of a consolidated fracture of the two bones of the forearm in a primeval man.

CARDIAC AFFECTIONS IN CONNECTION WITH NEURALGIA OF THE LEFT ARM.—The session terminated with an important communication by M. Potain on the above subject. It is well known that irritation of the digestive organs can produce, by reflex action, dilatation of the right side of the heart or even of the left ventricle, and, in consequence, periphtric neuralgia. This will be shown in the following cases: 1. A soldier was wounded in the left arm, and the limb was amputated. The healing of the stump caused a tension of the nerves, and the young man, long after his recovery, became subject to palpitations, suffocations, and hypertrophy of the heart. Injuries of this nature are often followed by hypochondria. 2. Another young man had his forearm crushed, and this resulted in a comminuted fracture, with painful cicatrices. After great fatigue he became subject to palpitations and oppression, so that it was necessary to give up all violent exertion. He had all the symptoms of hypertrophy of the heart, and was also hypochondriacal. 3. A soldier had the left armpit pierced by a ball, and it produced a reaction when healing which prevented his extending his arm, and necessitated forced movements which caused great pain. The patient suffered from palpitations and oppression, and some time after M. Potain discovered that there was a considerable hypertrophy of the heart. Here are three cases of patients who, although with a perfectly healthy heart before the wound was received, suffered afterwards from palpitations and hyper-

trophy. Here digitalis was indicated. These symptoms differ from those in which the hypertrophy being situated on the right side, is caused by irritation of the digestive organs. In such cases digitalis is of no use, but one must have recourse to treatment appropriate to digestion.—M. Verneuil also observed an analogous case. A patient from whom the left arm was amputated suffered great pain from the ends of the nerves of the brachial plexus fastened around the bone becoming compressed between the two during the healing of the stump. The patient suffered from hypochondria and cardiac affection. The resection of the arm was followed by cessation of the pain and the cardiac affection. M. Verneuil asked whether the left brachial plexus had not in every case a particular action on the heart, and consequently if in certain derivative indications on this organ it would not be better to act on the left arm than in other places?—M. Duployx has also seen a case of the same nature in which they had recourse to the extirpation of a neuroma with success.—M. Ollier also saw a case in which the pain, being in the leg, necessitated the resection of the internal saphena. This fact seemed to extend to the leg the remarks of M. Potain with reference to the arm. The cases collected up to the present seem to demonstrate that the influence on the part of neuralgia of the left side is considerable; but one need not be surprised to discover that periphtric nervous injuries of the right side exhibit analogous phenomena.—M. Lajdet knew of an old woman who suffered from periphtric pains in right arm, and who from time to time, and even when the symptoms were painful, suffered from palpitation, paleness, and suffocation. This tends to prove that traumatic neuralgia does not alone take part in the etiology of these secondary cardiac affections, and that spontaneous neuralgia is also capable of acting in the same manner.

SURGEON-MAJOR T. CAMPBELL TOLMIE is reported to be amongst the unfortunates wounded by the recent explosion and fire at the Cairo railway station.

THE University of Wurzburg, at its tercentenary jubilee, conferred the degree of "Doctor Philosophiæ Honorarius" upon Sir J. Lubbock and Prof. Huxley.

THE "Darwin Prize" of the Midland Union of Natural History Societies has been this year awarded to Prof. A. M. Marshall, D.Sc., M.D., for zoology.

THE annual election of the Court of Dental Examiners of the Irish College of Surgeons took place on Thursday last. The Court consisted of three Fellows of the College, Messrs. Richardson, E. Stoker, and O'Grady, who examine on anatomy, surgery, and physiology, and three dentists, who test the student in the specialities of dentistry—Dr. Sherlock, Messrs. Longford and Taylor. All these gentlemen offered themselves for re-election, and in addition Messrs. Thomson and Cunningham offered themselves for the surgical side of the Court, and Messrs. Stack, Corbet, junior, and Arthur Baker, for the dental side. The election was by the ballot vote of the entire Council, and it resulted in the selection of Messrs. Richardson, E. Stoker, and O'Grady to examine in the surgical subjects, and Messrs. Stack, Corbet, and Sherlock to examine in dentistry. Mr. Baker, not being registered in the Dental Register, was disqualified by the terms of the Dental Act.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 11, 1882.

THE OPENING OF THE WINTER SESSION.

HOWEVER much we may doubt the utility of introductory addresses in the abstract, it is impossible to question the earnestness with which the gentlemen deputed to undertake their composition and delivery enter on the task before them. That it is congenial to their inclinations we may at once assume from the fact of their agreeing to perform the duty of exhorting and encouraging young men about to commence acquaintance with medicine; it is unfortunate we cannot feel equal confidence in the value of the endeavours they make to acquit themselves satisfactorily. In spite of the numerically strong position held this year by introductory lecturers, the custom of opening the session with an oration having been revived at one or two hospitals, we do not consider that any additional argument has been adduced in favour of extending a custom of, at least, but vague advantage. Much more enjoyment, and much more benefit also, is secured to those who attend a friendly gathering of friends at a *soirée* than to the participators in an opening "ceremony" of the frigid formal type known as the introductory. In the former case the sense of being lectured at is not uncomfortably present in the mind of every student who puts in an appearance; in the latter, nothing short of absolute insensibility will serve to relieve the junior members of the auditory that they are not, personally and individually, objects of the orator's minatory utterances and flourishing cautions. Indeed, regarded in its best and most satisfactory light, the introductory

is but a piece of pretentiousness that would infinitely better be altogether omitted in future openings.

Nevertheless, although we are compelled to condemn the practice, we cannot overlook the meritorious manner in which it is often carried out; and no less this present year than on previous occasions have there been delivered addresses intrinsically valuable, not only on account of a careful construction and sound instruction, but even, also, as examples of rhetorical art. In our last issue we were enabled, by the courtesy of their respective authors, to present our readers with brief abstracts of all the addresses delivered on October 2nd in connection with metropolitan medical schools, and in several instances the complete lecture will be found amply to fulfil expectations of profitable perusal. The range of subjects selected was as wide as wise, and included such diverse topics as the General Medical Council—from a student's point of view—the scientific basis of homœopathy, and what should guide the conduct of medical students. All were not by any means of equal merit, but even the least important was far from ranking as inconsiderable.

At St. Mary's Hospital Dr. T. KING CHAMBERS delivered what all will regret to learn was a valedictory address, his long and honourable association as teacher and physician in the hospital being, by his own request, henceforth severed. Whether he was wise in selecting as the principal topic of his discourse the achievements of the General Medical Council may well be questioned, but not the fact of his devotion to a body that requires certainly more judicious "bolstering" than any but an enthusiastic supporter would essay to lend. The burden of Dr. Chambers's claim on behalf of the Council was that it had done a good deal for students by insisting on a fair amount of preliminary education on the part of every candidate for registration, and by separating the two principal professional examinations by a period of two years or more. He did not say what had been the cost in thousands of pounds sterling, and in years of time, at which these advantages had been gained, advantages purchasable at the expenditure of a suggestion, had it been but made in appropriate time and place. Dr. Chambers must have been only too conscious of the weakness of the cause he defended, but on this account we ought to honour all the more the attempt so gallantly made by him.

At University College Mr. MARCUS BECK delivered what may justly be regarded as the most important of all the addresses, and important chiefly on account of the very thorough analysis made by its author of the principles of medical education. It has evidently cost Mr. Beck a vast amount of labour in thought, and its conclusions are of the thoughtful kind that demand full and attentive consideration. We cannot afford now more than at any time previously to pass unheeded such remarks as are contained in this most valuable essay, for Mr. Beck's utterances carry the stamp of conviction in every word. Both on the subjects of study, and on the arrangements for study, he speaks with decision, free from hesitation, and to the point. He sees no good in "test" examination, and has small hopes of a

rational examining system under existing regulations ; nor, we fear, is he wrong in either respect.

At the London, Mr. HUTCHINSON read an essay on Carlyle before a delighted audience, but it was not in any sense an "introductory," being but one of the attractions of a successful *soirée*.

At St. Thomas's, Dr. SHARKEY was the orator, and claimed for experimental physiology the rights of free experiment, and after exposing the pretensions of homœopathsists, paid a warm tribute to the merits of Lister and Pasteur.

At St. George's, Dr. WATNEY, and at Westminster, Dr. HALL, delivered opening lectures respectively. Dr. Hall's address was a practical one to students pure and simple, and included advice for the guidance of their actions as well without as within the hospital.

A sad and distressing circumstance occurred in connection with the opening ceremony at Middlesex Hospital. The address was to have been delivered by Mr. Lyell, but that gentleman having been seized with illness, died on the very day he should have met the visitors attracted to hear his paper, a mournfulness impossible to conceal being thus imparted to the occasion.

THE CASE STATED AGAINST THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE BY THE ATTENDING PHYSICIAN.—II.

WE last week stated our preliminary objection to the proposal to compel the physician to notify infectious disease, based upon the fact that such proposal is without any precedent in English law, and altogether contrary to the principle of justice recognised and affirmed in our statute book. We pointed out that in the Public Health Act, the Contagious Diseases (Animals) Act, and every other law which deals with nuisances dangerous to health, the *onus* of reporting the existence of the *nidus* of infection, and abating it, is placed upon the occupier of the premises in which it exists, and never upon any other person. We also endeavoured to show that the law has heretofore fully recognised the privacy of the physician's relation with his patient on the same ground as it has respected the relation of solicitor to client, and priest to his flock ; that no Act of Parliament has ever existed to authorise public bodies to seize for their own uses the information acquired by private persons in their professional capacity, and we, therefore, appealed to constitutional precedent against the propositions of the compulsionists.

These views are not only, we are gratified to know, the selfish imaginings of the narrow medical mind (as Mr. Michael, Q.C., would say), for we find identical objections to the compulsionist proposals in the mouths of public journals of influence and repute, which do not care a fig for the doctor's sentiments upon any question in which public interests are involved. The *Spectator* of last week writes thus about the proposals which were put forth by the notificationists at the Social Science Congress :—

"The liberty of the subject" seems likely to degenerate, under medical treatment, into a mere phrase. To talk of the aim of good government as the assurance to each in-

dividual of the freest possible exercise of all his capacities of doing and enjoying, compatible with equal freedom on the part of his neighbour, is becoming old-fashioned. On all sides one hears the cry raised by all sorts of "fad"-mongers for compulsory legislation. The latest craze of this kind is the demand for the penalisation of disease, formulated at the recent Social Science Congress. To simple folk it appears a grievous thing enough to be the subject of any of the many ills to which poor human flesh is heir. But the doctors would treat the victim of a certain class of diseases as a sanitary criminal, punish somebody, "patient, medical attendant, or housekeeper," for omitting to give public notice of the offence, and lock up "zymotic" offenders. This is the heroic method of "stamping-out" disease, which we are gravely asked, nay, passionately adjured, to sanction by the terrors of the law. "Notification and isolation" is the medical phrase, but behind these seemingly innocent words lie fines, imprisonment, and forcible removal of the sick Englishman from his castle, at the very moment when he most needs the care and comfort of friends and home.

In sober earnest, to justify the legislation asked for at the Social Science Congress an infinitely stronger case must be made out than has yet been submitted to the public. In the case even of small-pox and scarlatina the difficulties attending the effectual working of any such system would be practically insuperable. The desire to escape its operation would be so strong that the family medical attendant would seize upon every plausible excuse for shirking the disagreeable and invidious duty of notification. Let us consider for a moment too the position of the unfortunate patient. He has not sinned against the community even from a hygienist's point of view ; the community, from some member of which he is supposed to have caught the disease, has sinned, if any sin there be in the matter, against him. He is to bear the whole punishment. On the whole the case is overwhelmingly against any system of Internal Quarantine. It is strange indeed in this age of sanitary science that so barbarous and retrograde a system should find advocates. But in their meritorious hatred of disease, medical men, whose enthusiasm must be admired even when not approved, sometimes lose sight of the general welfare. Specialists are too frequently deficient in catholicity, their intellect converges upon a point in the vast field open to it, and to that point an exaggerated importance is given. In the present instance, the hygienists propose a doubtful remedy, which, even if a good one, would be infinitely worse than the disease.

The advocates of compulsion have argued that the physician has nought to grumble at if he is forced to do public work against his will, and for an insignificant fee which he does not desire to earn, forsooth, because he enjoys a monopoly of medical practice granted him by the State, and is, therefore, morally liable to do the bidding of the State in all matters within his scope. We shall not stop to argue the question whether the State does really confer upon the physician any monopoly of medical practice, but shall at once take issue with such an argument on plain principles of justice and custom. Is the physician under any compliment to the State for being permitted to practise his profession to the exclusion of other people ? Does he not repay the public for the monopoly granted to him, not only by the expenditure of his time, money, and brains, on special education to fit himself to enjoy the monopoly, but by cash paid for leave to receive the monopoly, and by incessant, unrequited work for the public benefit ?

Surely the balance of obligation is overwhelmingly in favour of the medical profession when State monopoly and professional public work come to be placed one against

the other ; and if so, by what right save that of overwhelming necessity for the welfare of the community can the public claim to burthen any individual physician with any additional duty whatever which he is unwilling to perform. Pharmacists, solicitors, barristers, clergymen of the State Church, even cabmen, all are monopolists as regards the practice of their profession ; and does anyone talk of forcing them to do public work with or without adequate compensation ?

Having thus disposed of the constitutional principle of the proposed system, we come to discuss the far more important aspect of the question—

THE PRACTICABILITY OF COMPULSORY NOTIFICATION BY THE PHYSICIAN.

To put the question plainly, it is our contention that the proposed law would prove in practice worse than useless—that it would *not* cause infectious disease to be universally, or even generally, reported, but would rather cause it to be concealed ; that it would, therefore, rather increase than diminish zymotic disease, and would probably accentuate the evil which it aims at remedying. While admitting the advantage to be gained if the sanitary authority of each district could receive early knowledge of each infectious case, we assert that the most certain way to prevent this object being gained is to compel the physician to act as sanitary detective. In support of this contention, we appeal with confidence, firstly, to the experience of the influence heretofore exercised by the physician towards checking infectious disease ; and, secondly, to the obvious common-sense tendency of a law which would make the doctor the agent for imposing upon the house occupier the inconveniences and losses incident to protective sanitation.

How has the world waggled before notification of infectious disease was thought of ? A child shivered and sickened with no one knew what disease. The father instantly, on suspicion of an infectious fever, would run for the doctor, who, recognising that the disease was, say, scarlatina or small-pox, would at once, and without hesitation, give the parent his opinion, advise strongly the necessary isolation, prescribe the proper treatment, and warn the family of the danger themselves and their neighbours would run if precautions were neglected. The parent, animated by love of his child, and by apprehension lest the disease might extend to others of his family, and fearful that his business would be greatly injured if the house became saturated with infectious poison, or if the disease were communicated to others, would do his best to act upon the advice of the physician, and in the great majority of cases every purpose which compulsory notification is intended to serve would be attained. There is, in fact, in most cases, a fully sufficient paternal and self-interested stimulus at work in favour of isolation and other sanitary precautions, and there is only needed the necessary knowledge that the disease is infective, and the necessary advice as to what should be done. This knowledge and advice in the very earliest stage of the disease is invaluable, and any system which would discourage the intervention of the physician at such a moment could not but prove disastrous both to the patient, the family, and the public.

Having now pictured to ourselves what *is*, let us anticipate the condition of things which *is to be* under compulsory notification law. The child—receiving its contagion perhaps from carefully concealed infection—shivers and sickens. Does the parent rush off to the doctor ? Not at all. He at once recollects that he is the privileged citizen of a town in which notification and isolation are in full work, and that the doctor, if he calls him in, will have no choice but to advertise the infection to the civic sanitarians, and that he will at once become, thereby, liable to the attentions of the sanitary inspectors and whitewashers. Naturally he conceives that it will be quite time enough to face this annoyance when the disease has shown itself unmistakably ; so he keeps the child quiet in bed, probably in the nursery with other children, for three or four days, until the rash has come out. Thus the disease goes unchecked, the child's life is endangered, and the infection is very likely communicated to others of the family. But when there can be no longer any doubt as to the nature of the disease, does the parent then send for the doctor ? No, the disease is, he thinks, at its worst, the child he supposes is going on nicely, no one else has yet sickened, and, in any case, he might now get into serious trouble if he said anything about the matter ; so he does the best he can for himself—gets a bottle, perhaps, at the chemist's, and keeps the whole business a profound secret. And why has he run all this risk ? Because the apprehension of the disease being reported by the physician has caused him to hesitate about sending for medical help in the first instance, and he has thus been left without the advice and encouragement so needful under the circumstances.

We again appeal to the experience of the profession and the common sense of the public to confirm the accuracy of this picture, and of our anticipation that compulsory notification by the physician would mean wholesale concealment of disease, loss of the lives of the infected sick, and dissemination of the infection much more extensively than now takes place.

(To be continued.)

THE RISKS OF HEROIC DOSES.

On the 2nd of July last, Mr. S. R. Aitken died at Colombo, Ceylon, under circumstances which, in the opinion of the local authorities, called for an investigation, which was accordingly held, and the results are worthy of being placed before our readers. Mr. Aitken had been suffering for some time from tapeworm, and had been for two months and a-half under the care of Dr. J. D. Coghill, a local practitioner of great respectability, who had administered various remedies without, however, bringing away the head of the parasite. About ten days before his death he waited upon Dr. Coghill and told him that pieces of the worm were once more coming away in the excreta. He was much distressed thereat ; and patient and physician arranged that on Sunday, July 2nd, a great effort should be made to finally remove the annoyance. Against that day, the following prescription was compounded by a Mr. Campbell for Mr. Aitken, upon the prescription of Dr. Coghill. We give it *verbatim* from the document forming one of the

"exhibits" in the case, merely substituting words for some of the figures.

S. R. Aitken, Esq.

R. Ext. *Æth. Filicia*, Mas., one and a half ounces.

Pulv. *Kamelæ*, three drachms.

Pulv. *Granat. Rad.*, three drachms.

Mucil. *Acac.*

Syrup. *Simp.*, a sufficiency.

Aquæ *Cinnamomi*, to make 4 ounces.

Ft. Half to be taken at bed time and half at 2 a.m.

(Signed) J. D. M. C.

The pomegranate powder was omitted by the compounder, who informed Dr. Coghill of the fact.

The patient, on taking the first half of this prescription, suffered much distress, but took the remainder. He got worse and worse, and was seen by Dr. Coghill, who administered a quarter of a grain of morphia hypodermically, applied a large mustard plaster, and used some other very suitable remedies. Towards morning, however, the patient, who had suffered from diarrhoea, vomiting, and cramps, died, apparently from exhaustion; and Dr. Coghill on the same day certified his death as having been due to "choleraic diarrhoea."

The matter, however, was not allowed to drop, and without delay a solemn and carefully-conducted inquiry was held, at which much medical evidence was given. Dr. Carberry, who had conducted the post mortem examination, explained with care and skill the pathological appearances of the stomach and intestines; and wound up a very lucid testimony by saying, "My opinion is that death was due to exhaustion from diarrhoea, brought on by some irritant injected into the stomach." On his cross-examination, the same witness stated that the ether could be smelt very strongly throughout the intestines; a circumstance which pointed pretty plainly to what the irritant was.

The great point urged in Dr. Coghill's defence was that the prescription which he had employed, and after which, at all events, Mr. Aitken died, was taken from an authorised medical work of the first class, and that it had the *imprimatur* of the late Dr. William Brinton, the eminent London physician. This was admitted at the inquiry, but it was broadly hinted that the ounce and a-half of ethereal extract of male fern was a misprint.

We turned at once to the work in question, "Medical Therapeutics," by George A. Napheys, M.D., and at page 324 found the very prescription that was taken. There were some slight differences, dr. ij of kamela instead of dr. iij; and the cinnamon water was added up to oz. iij only. The ounce and a-half of male fern was there, and the directions were identical. Dr. Brinton's name was mentioned, and it was added that "he believes this superior to all the combinations for the ejection of *teniæ*."

If our copy were a first edition we would at once lay the blame upon the printer, who, like Molière's *père de famille*, "*est capable de tout*." Our copy is the seventh edition, published last year; and we are therefore fully justified in holding that the editor of the work is responsible for the prescription. This throws a broad shield over Dr. Coghill, who evidently inquired into what he was doing, and acted with some circumspection. A home practitioner within reach of medical schools and special teachers would not be likely to be

thus led astray; but liberal and generous allowance ought to be made to a colonial physician, who may well be excused for adopting the prescription so strongly recommended by a standard work of such calibre. That such a prescription should have passed unchallenged through seven editions clearly shows that big books are more bought than read, and that the work of the reviewer is often done in a very perfunctory way.

We consider it incumbent upon us to bring under the notice of special therapeutical observers and teachers, and of the profession generally, this heroic dose of male fern with its "adjuvans" of kamela. It is well known that some medicines may be administered in doses exceeding ordinary standards, and Dr. Napheys will probably justify the heroic quantities in question, maintaining, as was done at the inquiry, that the patient died from the exhaustion of diarrhoea and other complications from which he was suffering. Trousseau, Bartholow, and other standard authors, in their latest editions now before us, recommend male fern and kamela in the ordinary moderate doses familiar to the profession, and give no uncertain note of caution as to their irritant powers. But in the present case the ordinary dose had failed, whilst the heroic dose immediately expelled the worm, but caused, it was contended, the death of the patient subsequently. The dosology of these two important remedies can be settled by a very simple investigation; but it ought to be settled without delay, and no longer left an open question, to the confusion of country, and still more of colonial, practitioners; and still more important, to the danger of patients. It is but fair to Dr. Coghill to add that there was no prosecution; his *bona fides* and the authority quoted were evident, and the matter dropped after the initial inquiry.

Notes on Current Topics.

Sensational Suicide.

DURING the past week Paris has witnessed one of those horrible examples of sensational suicide which occur from time to time, and which excite feelings as well curious as shocking. The unfortunate victim in this case was a young girl about three-and-twenty years of age, who deliberately hurled herself from the highest accessible point of the Cathedral of Notre Dame, and falling on some iron railings below, was instantaneously killed. The body of the unfortunate woman is said to have been literally cut in two portions by the chisel-shaped heads of the railings, which clove her in the pelvic region: one-half remained fixed where it fell, the other, comprising the lower limbs chiefly, was taken up from the courtyard beneath. So far the causes which led to the commission of the deed have not been revealed, but the old explanation, misplaced affection, has of course been suggested. There is one aspect of cases of this description that lends them an interest to the psychologist, who cannot help but strive to find in the supposed mental excitement preceding the actual self-destruction some indications of a motive for the peculiar method adopted to secure it. Why such a mode of death should seem preferable to suicide by drowning or poison, or other equally facile means of ter-

minating existence must be determined by some definite circumstances; and it is not too much to believe that, could we but comprehend them, some light might be thrown on other equally ill-understood relations of suicide to psychical disturbance at the moment. However, the principal lesson to be learned from the mournful tragedy referred to is the necessity of guarding against any repetition of it by protecting the gallery whence the unfortunate Frenchwoman took the fatal plunge, in the same manner as the monument in London is prevented from being made an instrument of self-destruction by would-be suicides.

Death by Electricity.

SINCE the introduction of electric lighting took place several deaths have been recorded as following the accidental reception of strong currents by workmen and others. Not many months ago a man was killed through touching an improperly insulated conducting wire at Hatfield, and a few days ago a similar accident occurred in New York to a labourer who was engaged in repairing an elevated Brush light. He received the full force of the electric discharge from the supply-wire to the lamp, and was killed immediately. In this case it is impossible to avoid the suspicion that negligence must have in some way contributed to the fatality; else why was the current permitted to flow during the time a human being was at work on the apparatus? It should serve as a caution, where, notwithstanding, a caution of the kind ought to be needless, for in presence of so destructive an agent, every safeguard should be taken against chance misdirection. Speedy though death by such means must necessarily be, it is none the less horrible on that account, and unless safety is better consulted than seems sometimes to be the case, needless hostility may not improbably be excited against the progress of what is in more ways than one "the light of the future."

Newspaper Correspondents and the Medical Department of the Army.

THE apparently inevitable jealousy of the Medical Service of the Army, from which the "combatant" branch of the Service and those who write at their dictation seem to be unable to emancipate themselves, has exploded in a series of spiteful articles, which have appeared in the *Times*, *Daily Telegraph*, and *Standard* simultaneously. Newspaper correspondents at the seat of war live in a combatant atmosphere, and naturally respire the vapours which the fighting officer evolves when he comes to speak of "those d—d doctors." It might be reasonably expected, however, that these correspondents would be restrained by regard for the truth when they come to speak of matters medical; and in this particular instance, we regret to say, they seem not to have been influenced by any such mundane consideration. We have the best authority for stating that the sensational stories about the groans of the wounded soldiers submitted to the torture of operations without anæsthetics, are pure fiction—interesting and exciting to newspaper readers, no doubt, but absolutely untrue. There was at all times an abundance of chloroform, and the Life Guardsman who was stated to have had his shoulder amputated without it had as

much of it as could be desired. A couple of young officers who were wounded very early in the campaign were, we believe, brought to the base hospital before it was completely organised, and had to endure some inconveniences, which every soldier who goes to fight ought to be ready for; but so far from there being either disorganisation or neglect within the Medical Department in Egypt, we believe that its arrangements were wonderfully satisfactory, considering the circumstances; and we understand that Dr. Veale was complimented and thanked by Sir Garnet Wolseley on the efficiency of his hospital. It is not to be expected that youthful combatants would be free of the jealousy of the Medical Department which has been the fashion in military circles up to the death of the regimental system; but, we do think that newspaper correspondents who write for the public, and are handsomely paid to write the truth, might reasonably be expected to keep their minds free of such prejudice, and to adhere to fact, when the repute of an important branch of the Military Service is at stake.

The Prospects of the Schools.

THE present is an anxious time with managing and teaching authorities at the English schools of medicine. The principal question exciting interest, in many minds, is the all-important one of new entries, and while so many institutions are in competition for the favour of those who, after all, are chiefly considerable as supplying the sinews of war, in the shape of fees, some excitement must be created by publication of the numbers of new students entered. So far, the indications go to show that last year's returns will not be exceeded, even if they be reached, but still the result is by no means unsatisfactory; nor, if we judge by the needs of the profession, insufficient. Of the larger hospitals, St. Bartholomew's is likely to maintain the lead, and the London and St. Thomas's will not occupy positions far below the top of the list. How far Guy's can hope to regain its lost status remains to be seen when the completed schedule is announced, but it can hardly hope for some time to be regarded with the favour it was sure of receiving before the period of its unhappy troubles. Of the smaller hospitals, St. Mary's is to be congratulated on the popularity it enjoys, especially as it refuses to bid for the class of students who are attracted by the bait of a low scale of fees; and though it suffers in respect to actual numbers, when compared with its cheaper competitors, yet it certainly loses nothing in the eligibility of those who join its classes. The 15th of October being the last day of the registration period for students it is impossible to form any final estimate of the numbers entered just yet.

In respect of dissection material the outlook in most London hospitals is not encouraging. Nowhere, in fact, is there an abundance, and in most places an absolute deficiency exists. Though it does occasionally happen that as many bodies are procurable as are required for purposes of instruction, yet a year does not pass without reports of scarcity from one or more centres, so that it becomes a question of importance to consider in what way, if the present supply cannot be increased, it may be economically utilised. Certainly there is no present indication that the aspiration of the General Medical Council's

Examination Visitors regarding a practical test of every candidate in anatomy will be capable of realisation, for to starve the supply the schools enjoy in any degree would be to disastrously retard an essential study. How far the present limited number of subjects in hand at the various schools will be increased to meet the wants of dissectors remains to be seen. We can only hope the result may prove satisfactory.

Egyptian Ophthalmia.

OUR correspondent with the Army in Egypt informs us that owing to the conditions under which our troops have been living ophthalmia of a virulent form has been very rife. The attacks are not now nearly so numerous nor so severe as they were a fortnight since; but as all the conditions under which the soldiers were then living were favourable to its development, fears were entertained that it would produce a serious amount of injury to eyesight. Fortunately, there are signs of abatement, and as the men are drafted off for home, their transference to ship-board appears to produce an immediate change for the better. It has been very properly suggested, should an English army of occupation remain behind for any length of time in Egypt, that a class of medical men (specialists) should be sent out to take charge of and treat diseases of the eye. There would certainly be no difficulty in finding a number of young men with sufficient experience in the treatment of eye diseases, or who have acted as clinical assistants in our ophthalmic hospitals, ready to volunteer for the service. It is quite true that ophthalmia is merely an indication of an insanitary condition of camp life, and of the general debility into which the men are liable to fall from camping out in a country where eye diseases are most common among all classes. Almost every second person one meets with seems to be suffering, or has suffered, from some form of eye disease. The sand, heat, and glare are fruitful causes, and the flies, which are an incessant plague throughout the day, communicate the infectious discharge from one person to another. Then the long marches which the main body has had to take has been productive of much exhaustion, often greatly aggravated by lack of nourishment and hastily-cooked food, washed down by contaminated water. All these causes, combined with the foul smells of Egyptian camps and towns, are causes sufficient to predispose the strongest to disease, and are sure to take the pluck out of even veteran troops, as Napoleon, Abercrombie, and Sir David Baird discovered in years gone by.

The Contagious Diseases Acts.

Two memorials have recently been addressed to the Admiralty, from Portsmouth and Plymouth, giving the opinion of clergymen, medical practitioners, and other influential residents in those towns as to the working and result of the Contagious Diseases Act. The memorial from Portsmouth says:—"We consider that the Acts have been most judiciously and considerately carried out by those to whom their administration has been entrusted, and that no just cause of complaint can be brought against them. We feel assured that the operation of the Acts has been most beneficial in lessening the number of brothels and prostitutes, in improving the

appearance and behaviour of the women, and so freeing our town from the sad scenes of evil and disorder with which we were once only too familiar; in checking the progress, as well as mitigating, the virulence of disease; and, most especially, in affording the women an opportunity of being reclaimed from their sinful lives." That from Plymouth says:—"We are decidedly of opinion that, both from a physical and moral point of view, their action has been most beneficial. We believe that, although, if extended, their usefulness would soon be greatly increased and more universally recognised, they have been the means of relieving a great amount of physical suffering, while they have opened the road to reformation to many fallen women, who, were it not for the existence of these Acts, would never have had an opportunity of returning to a respectable course of life." The Mayors and Records of Portsmouth and Plymouth sign.

Persecution of Jewish Doctors in the Russian Army.

A NEW regulation which has just been promulgated by the Minister of War in Russia is a strange document, worthy of a past age. Israelitish doctors are numerous in the Russian army, and their professional devotion and scientific valour are well known to those who have seen them at work on the field of battle. Henceforth they are the objects of special laws. Their number is to be limited, and may not in the hospitals exceed half of the total effective of the medical staff of these establishments. They are to be entirely excluded from the sanitary corps of fortified places, and of central or divisional administration. Their admission to the military stations of Odessa, Wilna, Kiew, Varsovie, and Kharkoff has also been suspended until their number becomes less than five per cent. of the effective medical service. The same rules are applied to the Jewish students of the military academy at St. Petersburg. As for the doctors removed in consequence of these new laws, they are dismissed, and no matter what their acquired rights may be, are sent into other military portions of the empire. A strange way to recompense them for their services, and reward them for their courage, when more than one of them died gloriously on the field of battle in the late Turco-Russian war! In truth it is a sad spectacle for us civilised beings of the nineteenth century!

The Compulsory Notification of Infectious Diseases.

THE profession in Chester have recently had their attention directed to the proposal inserted in the new Improvement Act for that city, to the effect that medical attendants shall in future give notice to the Health Committee of the Town Council of the existence of infectious disease at the houses of their patients. The profession duly considered the matter, and it was resolved to memorialise the Town Council of Chester against the insertion of such clauses in the said Act, by respectfully submitting to it the following resolutions, which had been unanimously agreed to:—1. Whilst earnestly desiring, on sanitary grounds, the early and compulsory notification of the existence of infectious diseases in the city, we wish

to express our opinion that the compulsion to notify should be placed upon the householder or other person having charge of the infected case or premises, and not upon the medical attendant; and as we most strenuously protest against the principle which would, under a penalty for refusal, compel a man to assume towards his patients the attitude of a private detective or informer. 2. We feel assured that the most efficient sanitary benefit could be fully secured without violation of the confidential relationship which ought to exist between doctor and patient by the Town Council inviting—what will be accorded to it—the cordial co-operation of medical men in obtaining notification of such diseases, and in such manner as might be agreed upon in conference by the members of the profession and of the Council's Health Committee.

We are well pleased to observe that the medical practitioners of Chester have taken their stand against the attempt to impose compulsory notification upon them, and we are quite satisfied that if they and the profession generally stick to their opposition, the effort to lade them with this burthen will fail, notwithstanding the offensive bravado of Mr. Michael, Q.C. For the encouragement of the men of Chester, Liverpool, Nottingham, Bolton, and Dublin, who are fighting this contest on behalf of the profession generally, we have pleasure in printing the following recantation by the *British Medical Journal* of its compulsory notification creed. We find it in a semi-editorial article in the *Journal* of last Saturday:—

"There does not as yet, at any rate, seem to be reliable evidence that greater sanitary progress has been made, or a greater diminution in the general death-rate reached in those towns which have hitherto had Acts for compelling medical men to notify, than in others which have had to rely simply on general sanitary agencies. Bolton's published returns, on examination, seem to fall short of proving what we expected from them. This is a sad confession to have to make, and would appear fully to justify our Association in withdrawing its sanction from a principle which has seemed so little fruitful in hoped-for result hitherto, and to fall back on the only remaining one open to adoption, viz., that of imposing compulsion on the householder, a principle which the experience of Greenock seems to have shown not to be deficient in advantage."

Young Soldiers in Egypt.

ALLUDING to the unfavourable strictures which have been passed during recent years upon the material which, under the Short Service system, composes our reorganised army, Sir Garnet Wolseley writes:—"After a trial of an exceptionally severe kind, both in movement and in attack, I can say emphatically that I never wish to have under my orders better infantry battalions than those whom I am proud to have commanded at Tel-el-Kebir." The opinion here expressed by an eminent commander is apparently looked upon as a counter-blast against the declaration recently made by another eminent commander, and as a principle endorsed by the very great majority of men of extensive field experience. The daily and military journals have very naturally taken up the absolute divergence of views thus alluded to, and have endeavoured in various ways to explain it. From the discussion thus freely carried on in the lay press during the past week

the oft-expressed opinion in these columns as to the danger of the Short Service system in case of war has been fully borne out by facts; indeed, was recognised by the War Office authorities in the case of the troops recently despatched, as we find.—1. That before the battalions left England for service in Egypt a careful elimination of very young soldiers from the ranks was made. 2. That as many old soldiers as possible were drafted into the ranks to take the place of the young men who had been eliminated. 3. That notwithstanding the shortness of the campaign, the ratio of sickness was very large, and notably so among the younger men. Finally, it may be asked, why were the very young drafted out of the ranks, the older and more "hardened" men drafted into the ranks? Obviously because the military authorities were themselves aware that the former were physically, as in other respects, unequal to active service in Egypt, and that the latter were in all respects more to be trusted. The experience gained in previous campaigns, therefore, has been confirmed by that of Egypt, namely, that for all purposes of war, young soldiers are far less fitted than are those of mature age and training.

Nothing like Leather.

WE are amused to find in an introductory lecture delivered last week by Dr. Thomas King Chambers the following paragraph:—

"The hospital student now is fit to be received into any society, feels himself not out of place in any club or drawing-room, and will act wisely in availing himself of the privilege whenever he gets or makes his chance. Do not forget that it is the action of the Medical Council during the last few years which has more than anything helped the student to this position"!!!

We have been accustomed to hear of all the virtues of the Medical Council (from its own members); we already know (from them) that all the scientific ardour of our day, and all the progress which has been made towards improved education, are the offspring of the activity and zeal of the Medical Council. It remained for us to learn that the Medical Council had made "the hospital student fit to be received into any society," and we are thankful for the information.

Illegal Practice of Medicine.

THE court at Nîmes has just settled a most interesting point of right. It has confirmed the decision of the tribunal at Carpentras who had condemned a doctor for the illegal practice of medicine to a fine of 200 frs. M. B., a doctor of medicine, had acted as the accomplice of a quack of Vaucluse named Robert, by prescribing certain remedies prepared by him without knowing their composition. The medicine had the effect of aggravating the disease which it was supposed to cure.

THE sum of £2,600 has been given to the University College Hospital, London, by Mrs. Nathaniel Montefiore. It is to be invested for the permanent endowment of a bed in memory of her late brother, Sir Francis Henry Goldsmid, and a cot in memory of her son, Mr. Leonard Montefiore.

The Prison System of India.

CONGRESSMEN are the order of the day, but although they are found to be agreeable social gatherings, they too often display both a lack of science and good sense in their discussions of questions of the day. At the Social Science Congress held at Nottingham, a good deal of time was consumed over subjects not understood or so carefully studied as they should have been. Sir Pope Hennessey made an attempt to enlighten his audience upon the condition of the prisons of India, and about which he certainly seemed to require enlightening himself, for he uttered a good deal of nonsense about the cruelties practised in Bengal prisons, and which, he said, "were the means of hardening the criminal classes." He referred also to the humane reforms introduced by those who had nothing whatever to do with them, as usual, ignoring the valuable labours of a member of our profession—Dr. F. J. Monat, the late Inspector-General of Jails, Bengal, who laboured for many years to improve the prison system of India, and made it what it is at this moment. In a communication to the columns of a contemporary—*The Spectator*—Dr. Monat says:—"That the prison system of India had for many years very grave defects was well known to, and never concealed by, the prison authorities in that country; but that it ever created or hardened a criminal class has about as substantial a foundation in fact as would a camel elaborated from the inner consciousness of the fabled German philosopher. That the prison system of India was never deliberately cruel, even in its worst days, was shown by Lord Macaulay's Committee in 1838, which also produced abundant evidence that in the details of their internal economy there were none of the scandalous shortcomings discovered by Howard in the prisons of Europe. We found the Thugs, Dacoits, cattle stealers, secret poisoners, and all the other classes, Doms, Givallas, Dosadhs, Brywars, Bhanyas, Nuts, Cheynes, Sindhyas, Bunyas, and many other organised, and, in some cases, hereditary, classes of criminals in the country when it passed into our possession, and the inhuman system imagined by the disciple of Confucius from Hong Kong has done its best, not without success, to reclaim many of them, and to cause the disappearance of others from the criminal classes. And as for the share in reform claimed for Sir George Campbell, he simply quarrelled with the humanity, and not with the severity, of the system he found in use, and did his best to increase its pains and penalties, without the smallest appreciable effect in the diminution of crime that I have been able to discover. He erred gravely in attributing the irregularities which undoubtedly existed to the wrong cause, and in applying the wrong remedy. Hence the reversal of his policy, not by an unbelieving and recreant permanent official, for there are none such in the English meaning of the term in the constantly-changing administrations of India, but by one of the most popular and best of his own successors in the Government of Bengal. For the dietary punishments to which so much importance has been attributed, the Government of Bengal was in no way responsible. They were the outcome of the deliberations of a special and especially unwise Commission, appointed by the Government of India, and were adopted in spite of the protest of one of my successors in

the office of Inspector-General of Prisons in Bengal. Such punishments, from their extreme danger, were prohibited at my instance in the Prison Rules of the Province, which enacted that 'in no case is restriction of diet to be resorted to as a punishment of jail offences.' (Rule 278, Bengal Jail Regulations.) The rules had the sanction of law, under the provisions of Act II. of 1864, vesting the local Government with power to frame rules for the government of the prisons of the province."

So much for the extravagant incorrectness, if not absolute absurdity, of the news regarding the prison system of India, uttered by the Governor of Hong Kong.

NOTICE has been given that an examination of candidates for five appointments as Surgeon in Her Majesty's Indian Medical Service will be held in London in February, 1883.

DR. B. W. RICHARDSON, LL.D., F.R.S., having been requested by influential Liberals in Finsbury to contest the borough whenever a vacancy in its Parliamentary representation or a general election occurs, has written to the Executive Committee of the Finsbury Liberal Association to say that he shall be happy to meet them for the purpose of explaining his views as soon as his engagements will allow.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 23, Bombay 24, Madras 35; Paris 21; Geneva 21; Brussels 20; Amsterdam 19; Rotterdam 17; The Hague 21; Copenhagen 20; Stockholm 25; Christiania 20; St. Petersburg 38; Berlin 23; Hamburg 23; Dresden 27, Breslau 33, Munich 22, Vienna 19, Prague 23, Budapest 22, Trieste 26, Rome 22, Turin 17, Venice 26, New York 25, Brooklyn 26, Philadelphia 21, and Baltimore 27.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Derby 13; Bristol, Nottingham 14; Sheffield, Norwich 17; Edinburgh, Portsmouth, Birmingham, Cardiff 18; London 19; Leeds, Leicester, Bradford, Halifax 20; Hull, Brighton, Bolton, Blackburn, Huddersfield 21; Plymouth, Birkenhead 22; Dublin 23; Glasgow, Wolverhampton, Newcastle-on-Tyne 24; Liverpool, Oldham 25; Salford 26; Manchester 27; Sunderland 30; Preston 32.

THE annual death-rate from diarrhoea in the large towns declined to 1.0 per 1,000 last week. The highest annual rates from scarlet fever were 1.6 in Sheffield, 2.1 in Leicester, and 6.56 in Cardiff; from whooping-cough, 1.4 in Halifax and 1.6 in Preston; from measles, 1.0 in Hull and 4.4 in Sunderland; and from fever 1.2 both in Birkenhead and Leeds, and 1.3 in Liverpool. The 55 deaths from diphtheria included 28 in London, 15 in Glasgow, 2 in Dublin, 2 in Liverpool, and 2 in Leeds. Small-pox caused 10 deaths in London and its outer ring of suburban districts, one in Birmingham, one in Leeds, and one in Newcastle-upon-Tyne.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

NOTIFICATION OF INFECTIOUS DISEASES IN EDINBURGH.—We have heard so much of late of the advantages which Edinburgh has derived from the notification of disease that the following facts may be of interest to those who are clamouring for like advantages (?) for their towns :—A student at one of the dispensaries certified a case of scarlet fever, in the third flat of a common stair where there were several other children and lodgers, as one demanding immediate attention, and therefore removal to the fever hospital. Before, however, the case could be investigated, the uncle of the child called, and, learning how matters stood, propounded his ideas on the spirit of the law, and sent his own medical man, who certified that *no immediate attention was necessary*. The result is that the medical attendant will, in due course, receive the legal tender of half-a-crown, and also his fees guaranteed by the uncle for his attendance on the child. Scarlet fever is now epidemic in Edinburgh, which can scarcely cause surprise, when we consider the facts just mentioned. Every week we are refreshed with a list of the notified cases of disease, which may be of immense interest to the health authorities, but which, in the case of an epidemic of cholera, might lead to a panic, with disastrous results. There are some timid people to whom these reports would be fatal. They can scarcely be published to show the immense value of the principle of notification of disease except as a warning and proof that without compulsory isolation the mere notification of disease is a delusion and a snare. We gather from these reports that the system, as carried out in Edinburgh, has entirely broken down, for instead of infectious diseases becoming scarce, there does not appear to be the slightest abatement in their occurrence. During September 340 cases of scarlet fever were reported.

THE HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 30th ult., was 75, and the death-rate 17 per 1,000. Under 1 year there were 17 deaths, and above 60, 22, of which 3 were above 80, and 1 above 90. Diseases of the chest accounted for 26 deaths, and zymotic causes for 6, of which 2 were scarlet fever, 2 measles, 1 typhus fever, and 1 whooping-cough. The intimations numbered 111, comprising 3 fever, 96 scarlet fever, 8 measles, and 4 diphtheria.

DUNOON CONVALESCENT HOMES.—The annual meeting of the Dunoon Convalescent Homes was held in Glasgow, on the 2nd inst. From the report it appears that, under the excellent management of Miss Clugston and the directors, an increasingly large number of persons are enjoying the benefits of the Homes. A debt of £4,000, which remained after the erection of the new wing to the Homes, has been wiped off by the bazaar promoted by Miss Clugston, and there is now a balance in hand.

FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—At a very largely attended meeting of this body, held on the 2nd inst., Dr. Robert Scott Orr was for the third time re-elected President. During the past tenure of office Dr. Orr has discharged his duties with much courtesy, impartiality, and dignity, and his re-election is thus a grateful recognition of his services. At the same meeting Drs. P. A. Simpson, James Dunlop, Scott Orr, and MacVail were respectively appointed examiners in medical jurisprudence, surgery, medicine, and physiology. Dr. A. M. Buchanan was appointed an examiner in anatomy and surgery. Much interest is taken in the October meeting of the Faculty.

GREENOCK. — ACTION FOR £500 DAMAGES AGAINST MEDICAL MEN.—An action for £500 in the name of damages for the death of a girl against Dr. Gordon Cluckie, surgeon-oculist to the Greenock Fergusson Eye Infirmary, and Dr. Dobie, house-surgeon in the Greenock Infirmary, was brought before the Greenock Sheriff Court on the 6th inst. and debated. The action is at the instance of Henry Morrison, a plasterer, and his allegation is that the girl, his daughter, died through the fault of the defendants. The girl, who was eleven years of age, was being treated for a bad tumour in the left eye, and on the 29th of May last she was put under chloroform for the purpose of an operation. While the operation was proceeding she became sick, and shortly afterwards fell into a state of coma and died while in that unconscious condition. The averment of the pursuer is that the fatality occurred from unskilful treatment. The defence is that every care and skill were exercised by the defendants, and that "the death was a thing which no human skill could foresee or prevent, and is a thing which often accompanies such operations."

GLASGOW DEATH-RATE.—The Glasgow death-rate for the week ending with Saturday, the 30th ult., was 24 per 1,000 per annum, as compared with 20 in the preceding week. For the corresponding weeks in 1881, 1880, and 1879, death-rates of 18, 20, and 18 were registered.

GREENOCK. — THE FERGUSON EYE BEQUEST.—The annual meeting of the Fergusson Eye Bequest Trustees was held in the Council Chambers, Greenock, on the 2nd inst., Provost Campbell presiding. The report of Dr. Cluckie, who presides over the Eye Infirmary, was read. It stated that at the end of 1881 the number of patients under surgical treatment was 841. The total number of new patients who received surgical aid and medical treatment for diseases and injuries of the eye during 1882 was 3,283. Of that number 3,210 were treated at the out-door dispensary, while 73 were admitted into the hospital for treatment, thus making an increase over last year of 1,107. The report was adopted.

COUPAR. — THE FEVER EPIDEMIC.—A special meeting of the Coupar Sanitary Committee was held on the 6th inst., Baillie Simpson presiding, to take into consideration the recommendation of Dr. William Whitelaw, the medical officer of health, to close the public schools for a temporary period, with the view of extirpating the scarlet fever which has been prevalent among children for several months past. After mature deliberation, the Committee arrived at the conclusion that they could not in the present circumstances adopt the recommendation of the medical officer, and agreed to allow the report to lie on the table.

Literature.

OUTLINES OF THE SCIENCE AND PRACTICE OF MEDICINE. (a)

A SHORT time since we reviewed in these columns the seventh edition of Dr. Aitken's large two volume work on the same subject, and in commending it felt that it had now grown to a size which put it beyond the wants and capabilities of many readers. We felt, we said, in fact, that it had become to many a book for reference rather than for regular perusal.

The second edition of the shorter work now before us is a very creditable performance; and its perusal which is quite within ordinary reach, will give an excellent idea of the present state of medicine. To the student preparing for examination it will be welcome; and to another class, the overworked country practitioner who has no leisure for encyclopædic reading, and who yet wishes to keep up with the progress of science, it will be a great boon. We commend the work as a careful and conscientious summary of the essentials of medicine.

(a) "Outlines of the Science and Practice of Medicine." By William Aitken, M.D., F.R.S. London: Charles Griffin & Co. Second Edition, crown 8vo. Pp. 613.

DIPHTHERIA: ITS CAUSE, CURE, AND HOW TO ARREST IT. (a)

"FOR one person who can think, there are at least a hundred who can observe. An accurate observer is no doubt rare, but an accurate thinker is far rarer." The impediments under which the science of medicine suffers are tersely expressed in these sentences. In its influence on medical science bad thinking is bad, but bad observation is worse; while both combined is worse still. The literature of the profession is crowded with productions bearing the two last characteristics, and they are particularly manifest in a pamphlet under the above title which has been recently issued from "the second city of the empire." As it is not often that medical literature is adorned with such pure specimens of Oriental rhetoric, we quote the following exordium from the pamphlet under consideration:—"In the vast realm of science, constituted as it is by legions of merciless foes of the human race, and whose dominions branch forth wherever man is to be found—be it in the lands of eternal snow, where the Lslander is content to dwell and follow the monotonous routine which his fathers have pursued for generations before him; or be it in the more-highly-favoured regions of the temperate zone, where human intelligence has attained its acme of development, and where every year some further advance of science demonstrates the infinitude of man's intellectual powers; or be it in the tropics, resplendent in all that attracts the eye both in the vegetable and animal kingdoms, but where stagnant marshes lurk amidst all this beauty, and exhale the deadly venom of their breath—there is certainly no member of this universal community of disease which has marked more victims and slain greater numbers of the human race than diphtheria. . . . Were it possible to compute the numbers that have fallen victims to its ravages, what an array of figures would stand before us; far exceeding, I would venture to say, that which would indicate the countless hosts that have fallen in the multitude of battles that History holds in her lap [the simile may be excused on the part of a professed obstetrician], or the millions that have been engulfed by the relentless ocean." Now we are not prepared to doubt that this may be very fine writing, but in the face of facts we have no hesitation in characterising it as the language of gross hyperbole, or pure imagination. It is hardly worth inquiring how further advances of science could take place where human intelligence had reached its acme of development. This each one of our readers will attempt for himself to solve. It is no business of ours to unfold metaphysical conundrums. But is diphtheria so prevalent and so fatal a disease? Here the power of correct observation tells. Predilections for particular diseases from time to time take possession of communities, encouraged by medical men, who thus strive to obtain a reputation for the cure of the diseases for the time being fashionable. Even gods give place; so "congestion" has evidently had its day, and for some years past "diphtheria" has been the paramount dread of anxious parents. Speaking generally, men in large practice will acknowledge that genuine diphtheria is one of the rarest diseases they are called upon to treat; thus, an octogenarian practitioner, whose intelligence is undoubted, and who held an extensive *clientele*, informs us that during his long practice certainly not more than twenty cases of genuine diphtheria came under his notice, while our author speaks of the "innumerable" cases that came under his observation during the past ten years! Where the lurking error lies we will not take it upon ourselves to determine.

In opposition to the generally entertained opinion that diphtheria never takes on an epidemic form, our author at page 4 tells us "it is one of the oldest epidemics that is on record," but at page 16 of the same pamphlet we have, "How, then, does it appear in epidemics, so-called? The latter question I dispose of at once [a peculiarity of our author, by the way] by denying that it is epidemic. It is *not* an epidemic, but an endemic disease," &c.; and at page 23, "it is never epidemic," &c. Epidemics are usually regarded as the *infectious* diseases, but here again we are left in a helpless muddle, for we are informed "that it is not infectious—in the strict meaning of the word, mark me—I am prepared to prove: that it is contagious seems beyond doubt, but even this in a limited sense." On the following page occurs, "my reason for concluding that diphtheria is not infectious;" at page 23, "I will not proceed to give my reasons for believing that diphtheria is not an infectious disease;" page 31, "it is not an infectious disease," &c. Here, then, is a disease which is repeatedly alleged to be not *infectious*, and *contagious*, "but even this in a limited sense," but which yet is such an enemy to the human race that the numbers that have fallen victims to it exceed "the countless hosts that have fallen in the multitude of battles that History holds in her lap, or the millions that have been engulfed by the relentless ocean." Verily, it is difficult to conceive how it is communicated, or why the number of its victims should so far transcend human understanding! Being thus far unable to comprehend our author, we proceed to inquire whether he throws any light on the etiology of the disease, and for the main part we will allow him to speak for himself. In the hands of an Adam Smith

the deductive method of investigating the problems which science and human nature present may be admirable; generally speaking, it is not a method by which medical science is advanced, nor is it thus to be commended; but our author is a bold man who repeatedly shows his contempt for meaner intellects than his own, so by one flourish of his pen we get at his major premiss: "It should here be remembered that there is every reason for concluding that the microzymes which constitute the disease do not cease from their activity immediately upon the death of their victim, but continue their inroads upon the dead body until at length they make their way to the surface of the integument, and there present themselves as a focus of contagion." Of course, it is hardly worth doubting that diphtheria is caused by spores; but the remarkable activity and burrowing-power of the spore calls for attention, for in the interval between death and burial it has reached the surface, and is there present "as a focus of contagion." Here, at length, we have something tangible, a spore on the tonsil as the cause of diphtheria. But then the system becomes affected, and how does this happen? "Absorption would be a convenient term to employ, and by this hypothesis [our author speaks elsewhere of a statement which is 'only hypothetical, though hardly beyond dispute'] we might get over a difficulty; but I do not think it is by an act of the mucous membrane at all that the system becomes affected. Indeed, this seems to me quite an impossible event, for is the health of the mucous membrane not quite destroyed by its contact with the disease, and thus its absorbing capabilities removed? My opinion, on the contrary, is that it is due solely to the life and activity of the organisms themselves, and my reasons for inferring this are suggested by a careful study of the potato disease." We are not aware that any national bias has led to this "careful study." The "eagerness and voracity of the microzome" impel its progress into the tissues! These germs are ever present in the atmosphere, but not "in an active condition, at least as far as to be a *casus morbi*." Now the throat affection advances more rapidly when "once the constitution has become impregnated with the virus than it did prior to this stage of the disease;" and here follows the explanation in sentences which would have delighted the heart of Cobbet: "And we do not need to go far for an explanation of this fact. It is, that the microzymes which really constitute the disease, circulating in the blood, not to speak of the prostration arising from the local irritation, produce such a further state of prostration that the body, in the ratio that it loses its own vitality, becomes an easier prey to the virus, and a more fertile soil for its sustenance and growth." "If a person is in good health, and exposes himself in the ordinary way to the poison of diphtheria, the very great probability is he will not contract the disease." Two pages before, we are told, "It (diphtheria) is contracted by contagion when the secretions of an affected individual are implanted on a mucous membrane or a raw surface of a healthy person, and only then." When a person is healthy? An attempt, however, is made on page 7 to show that the vital resistance must be lowered before one can be susceptible to the poison of diphtheria; but while charity may grasp at the meaning, grammar refuses to parse it. "Let the same individual, however, inhale for a lengthened period an atmosphere vitiated by a sewer or any other putrid gas, or let him be supplied with insufficient food, or be deprived of a sufficient amount of sleep, or we will suppose he is weakened by over-fatigue, or it may be from anxiety that his bodily strength is lowered." Where has the "individual" gone to!

Our space will not permit us to devote further attention to this remarkable production. We can assure our readers there are yet gems in abundance to cull. As a pretentious exposition of the science of diphtheria it is a veritable curiosity, and as such we cordially recommend it to all interested in the study.

Notices to Correspondents.

623—CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. THOMAS.—We saw the book announced in the publishers' lists in our "Students' Number" (Sept. 20th) as "ready in October." We have not yet received a copy for review, so can give no opinion; but its author's reputation should be a sufficient guarantee.

MR. B. P. (York).—Thanks, but it is hardly suitable for our columns.

(a) "Diphtheria: its Cause, Cure, and How to Arrest It." By Robert Bell, M.D. London: J. and A. Churchill.

Students would be more likely to be interested, for which reason we would advise you to communicate with the Editor of the *Students' Journal*.

FEEES FOR CERTIFYING LUNATICS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I wish to bring under your notice a matter which I consider is a great grievance. I hold a dispensary appointment in a country district. The emoluments are small, and the private practice worth little or nothing.

Within the last month two persons in my district became insane, and were arrested by the police as dangerous lunatics; they were brought up at petty sessions in a neighbouring town and were examined and certified for by the dispensary doctor living in the town without my knowledge. I was ignored entirely, although I was obliged to go a distance of eight miles on a red ticket to visit one of these people.

Should not the magistrates have called on me to certify and not on the doctor into whose district they were brought simply because there were no available magistrates in my district? Was it not a breach of professional etiquette on the part of the doctor to examine lunatics from my district behind my back?

By inserting this letter in your next issue you will oblige,

Yours, &c.

September 29th, 1882.

A DISPENSARY DOCTOR.

P.S.—Have I any remedy against the magistrates or the doctor?

[By the 10th section of the Dangerous Lunatics Act the magistrates are bound to "call to their assistance the medical officer of the dispensary district in which they shall be at the time." Therefore our correspondent has no remedy except he can induce the police to take lunatics which are found within his district before magistrates sitting within the same. There is, we think, no breach of etiquette in the case.—ED.]

MR. HOWARD (Liverpool).—The essay on "Whooping Cough" which gained the Fothergillian Medal is, we understand, shortly to be issued in book form; the author reads a paper on the same subject at the Medical Society of London on Monday next.

W. H. R. (Kensington).—Thanks for the information, which we shall utilise after further inquiries.

MR. PARKER (Battersea).—Quite too elementary for our readers. You must have misdirected your envelope.

DR. W. J. STOTT (Haslingden) will please receive our best thanks.

MR. OSMAN VINCENT ON "HYSTERICAL SPINE"

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me in justice to your readers and myself to make a few corrections in your report of my paper on "Hysterical Spine" in last week's journal. I was absent from town when the proof was sent, hence my excuse for troubling you.

Surgeon to the National Hospital for the Deformed, at heading of paper, should read "late surgeon," &c.

Line 15, page 276, should read "this resting should be on a hard mattress."

Line 5, second column, page 276, should read "she could swing for three or four minutes."

Apologising for troubling you,

Believe me, yours faithfully,

45 Seymour Street, London, W.

OSMAN VINCENT.

MR. STEVENS (Aylesbury).—If possible.

MR. LIMONT (Newcastle Infirmary).—The cases are interesting, and will obtain early insertion.

M.D. (Dartford).—The subject of your inquiry was born in London in 1809. The idea that he was a "man of Kent" probably originated from the fact that his early life was spent at Dartford.

DR. W. S. (Glasgow).—The gentleman named died about two years since in London at the age of eighty.

AN INTENDING COMPETITOR.—You should apply for details to the Secretary; we can only announce the subjects for competition, having neither time nor space for the many minor points about which you are anxious.

MR. CROWTHER (Aahford).—Our Publisher informs us that the number is out of print, and that a previous notice of this fact was sent you by letter.

NOVUS.—You will find the matter referred to in our special number of September 20th.

MEETINGS OF THE SOCIETIES.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 7.30 o'clock, Council.—8 o'clock: Address by the President (Dr. J. Hughlings-Jackson, F.R.S.).—Mr. Rivington, "On the Symptoms, Diagnosis, and Treatment of Rupture of the Urinary Bladder."—Mr. Jennings, "On Transfusion Apparatus."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Thursday, Oct. 11th, at 8.30 p.m., Dr. Stephen Mackenzie, "On a Case of Chronic Tubercle of the Choroid and Brain."—Dr. Brailley, "On a Case of Large Tubercle Growing from near the Optic Disc."—Dr. Warner, "On a Case of Miliary Tubercle of the Choroid and Lung without Meningitis."—Mr. Nettleship, "On Certain Cases of Destructive Ophthalmitis in Children."—Living Specimens at 8 o'clock.

CLINICAL SOCIETY OF LONDON.—At the first meeting of the Society for the session, on Friday, Oct. 13th, the following papers will be read:—Dr. C. T. Williams, "Case of Phthisis treated by Residence at High Altitudes."—Mr. Golding-Bird, "Case of Excision of Tonsil for Epithelioma."—Mr. Clement Lucas, "Case of Excision of Base of Tongue, Tonsil, and Soft Palate for Epithelioma."—Mr. Walsham, "Case of Gunshot Injury of the Lower Jaw."

MEDICAL SOCIETY OF LONDON.—Monday, Oct. 16th, at 8.30 p.m., Introductory Address by the President (Mr. Francis Mason, F.R.C.S.).

After which Mr. T. M. Dolan, F.R.C.S., of Halifax, will read a *resumé* of his Fothergillian Prize Essay on "Whooping Cough."

PATHOLOGICAL SOCIETY OF LONDON.—Tuesday, Oct. 17th, at 8.30 p.m., First meeting of the session.

HARVEIAN SOCIETY OF LONDON.—Thursday, Oct. 19th, Mr. Pepper, "Trepanning Mastoid Cells in the Adult."—Paper by Mr. G. Barker, "Physiological Rest in the Treatment of Medical Cases" (concluded).

Vacancies.

Burton-on-Trent Infirmary.—House Surgeon. Salary, £130. Applications to be sent to the Hon. Sec. on or before Oct. 16th.

Croydon Union.—Medical Officer and Public Vaccinator for No. 9 District. Salary, £90, with fees extra. Applications must be sent to the Clerk on or before Oct. 16th.

Glenfies Union, Ardara Dispensary District.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Oct. 24th.

Granard Union, Finnea Dispensary District.—Medical Officer. Salary, £100, and £14 as Medical Officer of Health. Election, Oct. 14th.

Hackney Union.—Medical Officer. Salary, £80. Applications to be sent to the Clerk on or before Oct. 17th.

Parish of Birmingham.—Physician. Salary at the rate of £150 a-year. Applications to be sent to the Clerk to the Guardians not later than Oct. 23rd.

Torbay Hospital and Provident Dispensary, Torquay.—Senior House Surgeon and Senior Provident Medical Officer. Salary, £100. Applications to be addressed to the Hon. Sec. not later than Oct. 16th.

Appointments.

APPLEYARD, J., F.R.C.S. and M.B. Lond., Surgeon to the Bradford Infirmary.

BLAGG, A. F., M.B.C.S., Resident Medical Officer to the Rochdale Infirmary.

CARTER, T., L.R.C.P. Lond., M.B.C.S., Medical Officer for Richmond (Yorkshire) and the Union.

DENHAM, T. E., M.D., M.Ch.Q.U.I., Medical Officer for the Ireby District of the Wigton Union.

DOUZY, J. H., M.B.C.S., Second Assistant Medical Officer to the Worcester Pauper Lunatic Asylum.

ROBERTSON, D. W., L.R.C.P. Ed., M.B.C.S., Medical Officer for the Pickering District and Workhouse of the Pickering Union.

UNWIN, J. B., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Dunchurch District of the Rugby Union.

WEBSTER, G. L., M.B.C.S., Medical Officer for the Bowdley District of the Kidderminster Union.

WICKHAM, H., M.B.C.S., Medical Officer for the Fourth District of the Ormakirk Union.

Births.

COLTART.—Oct. 6th, at Ashbourne House, Epsom, the wife of W. W. Coltart, L.R.C.P., M.B.C.S., of a daughter.

CROSS.—Oct. 5th, at 7 Stanhope Terrace, London, the wife of John Cross, B.A., M.D. Cantab., of a son.

HUNT.—Oct. 3rd, at 101 Queen's Road, Dalston, the wife of Joseph W. Hunt, M.D., B.S. Lond., of a daughter.

MACSWINEY.—Oct. 3rd, at Greystones, co. Wicklow, the wife of S. M. MacSwiney, M.D., of a daughter.

Marriages.

JOHNSTON—MEDCALF.—Oct. 5, at Leven, Augustus Johnston, M.B., T.C.D., M.B.C.S.E., of Ambleside, to Judith Anne, daughter of the late W. Medcalf, of Newton-in-Cartmel.

HARRIS—CHALLINOR.—Oct. 3, at St. Edward's Church, Leek, Staffordshire, James Penn Harris, F.R.C.S., Liverpool, to Sarah Rosemond, daughter of the late Charles Challinor, Esq., of Liverpool.

PARKEE—MACLEAN.—Oct. 5, at St. Mary's, Bryanston Square, London, Charles Reginald Parkee, of Netherfield, Weybridge, to Adèle Anna Jane, eldest daughter of John Maclean, M.D., of 24 Portman Street, London, W.

Deaths.

BURKE.—Sept. 28, at Dalkey, Richard Burke, Esq., M.D., late of Manila.

CLARKE.—Oct. 1, at Great Yarmouth, Robert Whitmore Clarke, Deputy Inspector-General, R.N. (retired), aged 71.

DAVIES.—Sept. 30, at Hova Villas, Cliftonville, Brighton, W. St. G. Davies, M.D., Staff-Surgeon, R.N. (retired), aged 96.

HART.—Sept. 28, suddenly, of heart disease, Robert Alfred Hellings Hart, L.S.A., of Southwark, London, aged 28.

KERR.—Sept. 19, at Letterfrack, co. Galway, Alexander Spear Kerr, Esq., M.D., aged 87.

LYELL.—Oct. 2, at Harley Street, Cavendish Square, Robert Wiahart Lyell, M.D. Lond., F.R.C.S.E., aged 33.

MOORE.—Sept. 26, at Chapel Street, Salford, Huson Moore, L.R.C.P., aged 38.

SHANN.—Oct. 2, at his residence, 69 Petergate, York, George Shann, M.D., aged 73.

SETH.—Oct. 5, at his residence, West Brighton, Owen Seth, F.F.P.S. Glas., L.S.A.

TURKELL.—Oct. 4, at his residence, Park Street, Windsor, Samuel Turrell, M.D., L.R.C.P.L., Medical Officer of Health for Windsor, aged 60.

UNTHANK.—Oct. 1, at Derby Road, Nottingham, Anthony Unthank, M.B.C.S., aged 66.

WEST.—Sept. 29, at Yeolmbridge, Edward Lawrence West, M.R.C.P. Ed., M.B.C.S., of Launceston, aged 53.

FASHION IN MEDICINE.

Being the Inaugural Address on the opening of the Session of the Medical Institution, Liverpool, Oct. 12th, 1882.

By T. SHADFORD WALKER, M.R.C.S., President,
Surgeon to the Liverpool Eye and Ear Infirmary.

In addressing an audience composed of men representing every branch of the medical profession, it did not seem appropriate to choose a theme which could only be of interest to a minority of those present. I therefore put aside the temptation to speak on special matters, and decided to lay before you some reflections on subjects of general concern to the welfare of our body.

The subject of my address to-night is the Influence of Fashion on Medical Practice and its Results. The time at my disposal only permits me to bring forward two illustrations of the subject. These are—

First. The practice of blood-letting.

Second. The administration of stimulants.

Now to the first point. Only those among us who have passed the meridian of life can remember the time when blood-letting, or phlebotomy, as it was called, was the universal practice. Not to possess a well-filled case of lancets and not to use them on all possible occasions was a thing unknown. To doubt the efficacy of blood-letting in all cases where the vital fluid was distributed, or was supposed to be distributed in excess, which practically meant the same thing, was for a long period, up to about fifty years ago, a heresy undreamed of. Nay, to such a pass did things attain, that strong and healthy people used to resort regularly to the general practitioner all through the country, every spring and fall, to be bled, not in small dribblets which could not affect the constitution, but *pleno rivo usque ad deliquium*, that is, standing until they dropped on the floor. Here, one would think, was a practice resting on a sure basis of established observation of morbid conditions, or of well-ascertained fact,

too firmly rooted to be overturned. Yet by the efforts of one man (Marshall Hall), mainly by the reading of one paper, in which the ill effects of the unintelligent use of blood-letting were pointed out, phlebotomy passed away like a dream, and now, in this present year of grace, I doubt whether the younger portion of this audience either ever saw a lancet used for this purpose, or would know the proper way to set about using it, without a previous dip into an old-fashioned work on minor surgery. Is it not, to say the least, a strange thing that a body of men calling themselves, and supposed by the public to be, scientific, should first declare a certain practice to be a powerful and necessary means of cure, should wield a formidable weapon over the length and breadth of the land, and should, after all, suddenly turn round and just as emphatically stigmatise that process as mischievous and to be avoided by all prudent and well-educated physicians? Was it scientific, or calculated to raise the profession in the estimation of the public? Was it not rather playing into the hands of the empiric and the unqualified practitioner, as well as exciting distrust in observant minds amongst the laity? Here was a complete change of front. And yet there must have been physicians who knew better, who recognised the great value of phlebotomy in giving relief to urgent symptoms in cases of acute disease, and so saving the strength of the patient for the critical period of the struggle back to health. But they were overborne by the tide of the new opinions, swelled by the approving chorus from the outside, raised by those who, either in their own persons or in the persons of their friends, had suffered from the indiscriminating application of the lancet. Of course, reasons abounded in plenty for the abandonment of the old ground. Amongst others, one found a good deal of favour. The type of disease was said to have changed from a sthenic to an asthenic form. This was more particularly insisted upon after the great epidemic of influenza which spread all over the country in 1837. One of the chief symptoms observed was great depression of spirits, combined with a very feeble state of the circulation. But this was only a

transitory state of things. The constitution of the English people as a whole could not be permanently affected by the occurrence and effects of a single epidemic, however widespread its ravages. Here and there practitioners were found, after the novelty of the change had worn off, who had the courage of their convictions, and who, in suitable cases, reverted to the former practice with marked success. They proved that an amount of blood could be suddenly or rapidly removed from the general circulation without inducing anything more than a temporary anæmia, and without causing any permanent sickness. In the practice of every ophthalmic hospital at the present day, the good effects of depletion of the overloaded blood-vessels in cases of acute inflammation are so frequently manifested that the practice of blood-letting has never been relinquished. The relief to pain, often of an aggravated and exhausting character, so afforded, and the increased action of the local remedies which follows the bleeding, are too marked to be overlooked.

If, then, where the engorged organ is in full view, under careful observation we see such excellent results, why may we not, or rather why ought we not, to expect equally good effects to follow the use of the lancet or the cupping glass in cautious hands, where the pleura, the tissue of the lungs, or of the brain are attacked, in a similar manner and to the same extent. I am sure that there are members of this society who, if they were to narrate their experience, could bring forward corroborative cases in sufficient numbers to convince any candid hearer of the truth of the views I am now expressing. It is not pleasant to think of the number of useful members of society in the prime of life whose career has been cut short in a few days by acute diseases of the pleura, bronchi, and lung tissue, who might be still with us had a free use of the lancet been made at the onset of the attack. Of course, I need hardly say that I speak of uncomplicated cases occurring in healthy persons exposed to cold without sufficiently warm clothing.

But it may be asked, how did all this come about? Why did the pendulum swing so far in the opposite direction? The answer is not far to seek. It was because the practice of blood-letting became one of mere routine, applied without discrimination in every sort of disease which was supposed to be congestive or inflammatory. It was because the weapon was in the hands of men, the truth must be confessed, many of whom were uneducated or insufficiently educated, and seeing that the time devoted to study seldom exceeded twelve months, they had few or no opportunities of holding communication with each other on professional topics, or of giving information by comparing experiences, except in the metropolis or the great cities, where medical societies existed, and where medical journals were started. These points we, who live in the days of telephones, telegraphs, and every means for facilitating intercourse between man and man, are in danger of forgetting or overlooking.

How differently are we situated. The extension of the curriculum of the student of our day, the ever-increasing stringency and the more practical nature of the examination he has to undergo, the full supply of information on all medical topics afforded by the medical press (not always too trustworthy), place the young practitioner of to-day in a far better position for testing the accuracy of the theories which lie at the root of practice, than his predecessors of fifty years ago enjoyed. It is to him we must look with well-founded hope, if our theories of improved education are worth anything, equipped as he now is with clinical thermometer, sphygmograph, ophthalmoscope, and other arms of precision, for more accurate observation and more enlightened practice. May we not hope that the practitioners of the present will, taking warning by the example of the complete reversal of opinion in a former generation, prove themselves equal to the scientific use of the lancet in suitable cases, so that there may be no possibility of our living to witness a repetition of the scare I have just described, or of a right-about-face

evolution on the part of the profession in the practice of the Art of Medicine.

I now come to the second illustration of the effects of fashion in the treatment of disease, namely, the administration of alcoholic stimulants.

Let us see how the matter stands now.

If we carefully consider what has happened, within recent years, as to the administration of stimulants in disease, it is calculated to shake our confidence in the capacity of our profession, as a body, to come to any scientifically based and generally acted upon resolution, as to the proper use of the drug. Alcohol, in spite of all the advantages in the medical education of the present day.

What can be thought of the opinion of the profession on this point, or in what estimation it is likely to be held by any one who has paid attention to the subject, when we find such violent fluctuations of opinion as have occurred during the past half century. First, that alcoholic stimulants were withheld in all fevers and inflammatory disorders; next, that strong wines and ardent spirits were given, often in enormous quantities, even to children, in all such cases, as well as in cases of extreme debility; whilst quite recently, the medical compass has been boxed again, as we see, by the signatures appended to a document, on the part of a large number of leading practitioners in both London and the provinces, in favour of avoiding, as much as possible, the administration of alcohol in disease, especially to women.

Now, what are we to think on this question?

I ask my hearers, does it not show that we are at sea, on the matter, that we have no principle of any value to guide us, or that we are afraid to formulate it?

Or, are we in this business, as in the old days on the blood-letting question, to manifest our gregarious nature, and all jump through the gap, after the one who jumped first, like so many sheep?

Is any attempt made, in a truly scientific manner, at any medical school in the Kingdom to teach students what the action of alcohol is when given to a sick person, in what form it ought to be administered, and what its dietetic value is—first, in acute disease, and secondly, in chronic, or in the period of convalescence from either? I am afraid not; at least, I do not recollect an instance.

And if so, how are the young practitioners to obtain the information which the authorities of the various schools have neglected to teach?

Then again, why, may I ask, is it not the universal practice when ordering this drug to prescribe the exact dose and frequency of administration, as with other powerful remedies? Surely some distinct directions should be given for gradually diminishing the quantity and frequency of the dose, so as to prevent the formation of intemperate habits. A charge of neglect in this matter is not very infrequently made against the profession as an excuse for the commencement of the habit, though not always with justice.

I am aware that this very important question is, more particularly of late years, complicated by the fact that many persons feel a strong and conscientious objection to the use of alcoholic stimulants at all, and under any circumstances. I am not, however, addressing myself to the consideration of individual peculiarities of thought or feeling, for or against, the daily use of some one of the many forms of alcohol.

We all come into contact with the fanatical advocates of total abstinence in every form and under all circumstances, who would exclude it as completely from the sick room and hospital as from the table. In the face of all this, it behoves us to agree on some definite principle that shall guide us in the use of alcoholic stimulants, and enable us to meet the arguments of the total abstainers. Failing some such action on our part, their societies, ever increasing in numbers and zeal, will assuredly influence general lay opinion in the direction just indicated.

Already pressure has been brought to bear on the managers of many workhouse hospitals on the score of economy, in spite of the individual protests of the responsible medical officers. If not arrested by the authoritative voice of the great majority of the profession, where is this interference with the judgment and freedom of action of medical men to stop?

Let us not any longer dally with the question. It will prove a much more difficult task to reverse a wrong decision than by timely action to prevent it.

I believe that the members of the Liverpool Medical Institution, from their number, activity, and medical knowledge, could, if they would, afford great help in arriving at correct conclusions on the point. By so doing, they would aid in rescuing our profession from recurring vacillations and recantations of opinion, which cannot fail to bring discredit upon it and excite public derision.

Ought we, as a trained and educated body of men, with all the evidence before us for coming to a correct conclusion, and specially fitted to deal with questions of treatment on which opinion is likely to be divided, ought we, I say, to allow such questions as I have, however imperfectly, brought to your notice to drift about unsettled, until they are taken up by others outside our pale, and decided, as one at least is being decided, with or without our consent? I feel sure that your answer will be in the negative. And if we act according to the best of our ability with singlemindedness, and a regard for truth and the public weal, so shall we secure increased respect for our profession, and so shall we prosper in our work.

ON THE METHODS OF DIAGNOSIS IN DISEASES OF THE NERVOUS SYSTEM.

By E. C. SEGUIN, M.D.,

Clinical Professor of Diseases of the Nervous System in the College of Physicians and Surgeons, New York.

LECTURE II.

GENTLEMEN,—In my last lecture I spoke of the objective part of a diagnosis, and pointed out in brief the principal disturbances of function which we are able to recognise in an examination, and exhibited and described the instruments by means of which we detected and measured the degree of such disturbances. I referred to certain methods of diagnosis which fall within the province of other specialties, more particularly the use of the ophthalmoscope. To-day I wish to extend my remarks to certain other methods of diagnosis, a knowledge of which is essential to the success of the nervous specialist. Among these may be mentioned auscultation and percussion in the physical examination of the chest and abdomen, the use of specula and tuning-forks in the examination of the ear and testing the hearing, the use of the laryngoscope in the examination of the larynx, the chemical and microscopical examination of the urine, and so on.

Of course the neurologist cannot be expert in all these methods of examination; but, on the other hand, he cannot be expected to make a satisfactory study of his patients without a certain degree of skill in these diagnostic manoeuvres. With respect to urine, it is especially important that he should be able to make a satisfactory examination of it. I may say that I have often had occasion, during the past five or six years, to prove the dependence of an obstinate and severe form of headache upon the existence of contracted kidneys. Detecting the presence of an excess of phosphates, or of an excess of urea, or the condition known as oxaluria, is often a very important factor in nervous diagnosis. It is not sufficient to make a single examination of a sample of urine in a test-tube, by boiling it and adding acid, but the amount of urine secreted in twenty-four hours should be known, and,

from repeated examinations of it, the existence or non-existence of morbid conditions noted.

By an examination of the genital organs, both male and female, much important information may be derived.

A knowledge of the presence of versions, flexions, or tumours of the womb, ovarian disease, deep-seated stricture, or narrow anterior urethra, and many other abnormal conditions of the genital tract, will lead to the adoption of appropriate treatment; whereas, without such knowledge, drugs may be prescribed and electric batteries used, for an indefinite time, without relief.

I next propose to speak of the principles of diagnosis, and will divide the disorders to be diagnosed into two classes, organic and functional. This division presupposes a difference in the method of examination. The logical difference between the methods of study is very marked. The complete and satisfactory recognition of organic diseases of the nervous system involves a triple diagnosis. It is arrived at inductively by means of the history given by the patient, by means of the testimony of friends, by means of the various methods of physical examination, and, to a certain extent, deductively by knowledge you have acquired from experience, books, &c.

The first diagnosis is that of the symptoms, and these may be considered as constituting what the Germans call the "symptom-group." Second, we make a diagnosis of the location of the lesion, and it is this diagnosis which is just now interesting observers most. In the third place, we have to determine the nature of the lesion, which is, perhaps, of the greatest practical importance to the physician. We first determine the symptoms, next the situation of the lesion producing the symptoms, and afterward try to determine the pathological nature of the lesion.

The first diagnosis is made exclusively from a history of the case and an objective examination. We learn from the statements of the patient and friends, and an ocular examination, what has taken place during the few days or weeks preceding. We determine, by methods pointed out in the last lecture, whether there exists paralysis, spasms, ataxia, anæsthesia, and so on. The mental symptoms to be noted are loss of memory, delusions, or uncontrollable manifestations. We thoroughly overhaul the person of the patient physically and psychically, and we determine what functions are well performed, and which are interfered with. During the next few weeks you will have in every lecture an illustration of how to make this diagnosis: for example, a patient will come into the clinic complaining of weakness of the muscles of the face, arm, and leg, upon one side of the body.

We determine the existence of this condition by the testimony of the patient and his friends, by inspecting the patient, by the application of tests which have been already described to you, and from the data thus collected decide that the case is properly one of hemiplegia. Again, a patient may come in complaining of weakness of both legs, while the arms are normal, and we decide that he is suffering from paraplegia. A patient presenting with no paralysis and no anæsthesia, but with an inability to direct the movement of his legs, we say he is suffering from inco-ordination or ataxia. If a patient presents with one eye turned outward and a drooping of the lid, we designate this condition as one of ptosis with strabismus. If a patient has loss of sensibility, we call it anæsthesia, and ascribe particular names, in accordance with the distribution of the anæsthesia. When anæsthesia of one-half of the body exists, we call it hemi-anæsthesia. If, upon examination, vision is found to exist only in one-half of the visual field, we call the condition one of hemiopia. In this manner we indicate the condition of the various organs throughout the body, and determine in what way they differ from the normal, and to the conditions found to exist we give certain names which represent the symptom-group.

Sometimes we are only able to discover a single symptom, and have to go on to the next diagnosis. My observations have led me to believe that, in making the first diagnosis, the testimony of the patient is too fre-

quently used as a sufficient guide, and pains are not taken to go over the body and carefully determine the extent of paralysis, ataxia, or areas of anæsthesia, and make a record of what is found. There is often a lack of definiteness in examinations of nervous cases which practitioners would not allow in chest diseases. From the time of Laennec no physician has considered his examination of the chest complete without having determined the nature and character of the signs, so that he could tell another physician what he had seen or heard, in such a way as to lead him to a correct diagnosis. We are attempting to apply the same exact method to the study of nervous diseases, and are making very great progress.

The second diagnosis, that of the location of the lesion, is of importance. It is not directly dependent upon observations made with our eyes, instruments, &c., but upon anatomical and physiological knowledge. It is very seldom that a nervous lesion is visible, except in cases resulting from injury or external violence. We have to determine the situation of the lesion from the symptoms present, by means of our acquired knowledge of physiology and anatomy. Hence it is that exact and minute anatomical knowledge is more essential for the diagnosis of nervous diseases than for that of any other.

I will take up some of the symptom-groups of which I spoke a few moments ago, as determined hypothetically in my remarks: for example, that of hemiplegia. We revert to our acquired knowledge concerning the nervous supply of the paralysed parts derived from the spinal cord and brain. We also revert to the experiments made upon the central nervous system of higher animals within the last fifteen years, and our empirical knowledge of lesions discovered after death in cases of hemiplegia studied during life. For the present I will rely more particularly upon anatomical and experimental data. We know that the limbs of one side of the body receive innervation from the opposite side of the brain. You will hear it said that this law is not valid; but I say to you it is a good law, and a knowledge of it will be of great help to you in the study of nervous diseases. The few exceptions which are quoted in support of the idea of its invalidity are capable of many interpretations which leave the law untouched for all practical purposes. I propose to discuss this matter of the crossing of nerve-fibres from one side to the other, in a subsequent lecture. Bearing in mind, then, that either side of the body is innervated from the opposite side of the brain, we at once locate the lesion on the opposite side from that in which the paralysis is found to be present in our hypothetical case of hemiplegia. Partly from the study of anatomy, partly from the study of embryology, and partly from a knowledge of what recent experimental physiology has taught, we know that the whole of one side of the brain has not the power of moving all the opposite side of the body. Let us suppose a case of left hemiplegia with the lesion in the right hemisphere. I may remark that the whole right hemisphere is not connected with the opposite cheek, arm, and foot. Recent experiments have shown that a relatively small part of the right hemisphere has power over the left cheek, hand, and leg, and this part of the hemisphere is in the median region, and embraces a small number of convolutions—certainly not more than half of them. We have records of positive knowledge, to the effect that the anterior and posterior extremities of the hemispheres have no motor power over the opposite side. Still basing ourselves upon anatomical researches and physiological experiments, we know that the muscles of the left side of the face are innervated by a small part of the right frontal lobe, we know that the upper extremity is innervated by a small part of the brain known as the ascending frontal and parietal convolutions. We further note that the part of this right hemisphere which is connected with the leg is situated at a different point, nearer the median line, near and in the longitudinal fissure, and more posteriorly. In other words, we have determined with great accuracy the motor area of the right hemisphere, and the centres for the movements of the cheek, arm, and leg. With respect

to the sensory function of the hemisphere our knowledge is not so exact, but we know that loss of sensibility on one side of the body indicates a lesion in the opposite half of the brain; that right hemi-anæsthesia indicates a lesion in the left hemisphere—one situated in all probability in parts posterior to the motor area. These are not theo-

The above woodcut is modified from Ferrier: letters and figures the same.—S, fissure of Sylvius; c, fissure of Rolando; po, parieto-occipital fissure. Circle II., seat of lesions which convulse or paralyse the upper extremity of the opposite side. Dotted Circle III., seat of lesions which probably convulse or paralyse the face on the opposite side. Dotted Oval IV., seat of lesions which convulse or paralyse the lower extremity of the opposite side. These districts receive their blood-supply from the middle cerebral artery.

retical guides; they are valuable life laws, and there has not a year passed, within the last five years, that I have not seen cases illustrative of them, and verified them by post-mortem examination. Bearing upon this point, I may say that I published two cases this year, (a) in which the diagnosis was made, by means of a knowledge of these laws, with such accuracy that we were within half an inch to one inch of the actual seat of the lesion. In a number of my cases the lesion was found to be situated exactly where it was diagnosed during life. Records of similar cases may be found in American, English, and Continental journals generally.

We are also able to locate, upon similar anatomical and physiological principles, lesions of the spinal cord. In paraplegia we can determine the height of the lesion quite accurately, by means of our knowledge of the points at which nerves are given off from the spinal cord. To quote a case: a patient falls and receives a dislocation and fracture of the seventh cervical vertebra, compressing the cord at this point. The patient at once presents anæsthesia and paralysis below the clavicles and in the distribution of the ulnar nerve. Now we know, from anatomical and some curious electrical (b) examinations, that the fibres of the ulnar nerve arise from the lower part of the cervical enlargement, and that its trunk is made up by the last cervical and first dorsal nerves. Hence it is that compression of the cord at this point gives rise to paralyses of parts supplied by this nerve. When I come to speak of the diseases of the spinal cord, I will give in detail the rules for determining the height of any lesion, by means of which a diagnosis of extreme accuracy can now be made. We can locate a lesion in the anterior and posterior portions of the cord, with reference to the white and grey matter. We know that

(a) *Journal of Nervous and Mental Diseases*, July, 1881, p. 510.

(b) In two or three cases of spinal irritation I have noticed that placing the cathode over the sixth and seventh dorsal vertebrae, with the anode near by upon an indifferent part, and passing a strong current, the patient, though devoid of any anatomical knowledge, has described a prickling sensation in the little and ring fingers of each hand. This is evidence of the cathodal excitation of the origin of the ulnar nerve.

paralysis, accompanied by great muscular atrophy and degenerative electrical reactions, is due to a lesion in the anterior gray matter of the spinal cord. We know that in ataxia of the legs and arms, in which there is no true paralysis, the lesion is strictly limited to the posterior white columns. A patient comes in with a stiff gait, with crossing of the legs, but without anæsthesia or ataxia; we are certain that the lesion is in the lateral columns. In peripheral paralysis—as, for example, when due to injuries of the nerves—a diagnosis is usually very easy to make, for we have an injury or scar to guide us. Or a nerve may be cut in a surgical manœuvre, and we can at once determine the seat of the lesion. But, in some cases, the seat of the lesion is not apparent, and we must judge of it by medical logic. In the diagnosis of such cases we are very much helped by an anatomical law, which you probably have not found in your books, and which summarises the distribution of the sensory and motor filaments of nerve-trunks. I refer to the law of Van der Kolk, namely, that a spinal nerve gives its motor branches to the muscles as instruments of motion, and its sensitive branches to the part moved. (a) In other words, throughout the body the sensitive branches of a mixed nerve run to the part of the skin which is moved by the muscles receiving motor filaments from the same nerve-trunk. It is very easy to call to mind examples of this law. A sciatic nerve, for example, sends its sensory filaments to the calf of the leg and the foot, which parts are moved by the posterior thigh muscles and both sets of tibial muscles, which receive their motor filaments from the sciatic. In the arm the musculocutaneous nerve gives motor fibres to the biceps and brachialis anticus, and its sensory filaments go to the integument of the forearm, which is the part moved by the above-named muscles.

Wherever you study this law you will find it absolute. You may meet with some apparent exceptions, but they are only apparent. An apparent exception is found in the head, where the trigeminal plays the part of sensory roots for most of the cranial motor nerves. Studied in the light of this law, a patient presenting anæsthesia of the little and ring fingers, and outer part of the palm, with paralysis of the interossei and inner half of the thenar group, has a lesion of the ulnar nerve, probably above the wrist. If the flexor carpi ulnaris is paralysed, the lesion is certainly above the elbow. Again, paralysis of the extensors of the carpus and fingers, with anæsthesia of the dorsum of the hand on its radial side, indicates a lesion of the musculospinal nerve.

We now come to the third diagnosis—that of the nature of the lesion. This should not be made until the others have been determined carefully; and, here again, we use entirely different principles of logic. This diagnosis is more empirical—more uncertain. The third diagnosis can be best made by the physician who has had the greatest experience with disease in general; and here comes in the strongest argument for the postponement of special practice until you have acquired a thorough knowledge of general pathology. It is just here that one realises the insufficiency of normal anatomical and physiological study. It makes no difference what the symptoms are, or where the lesion is located, for that does not determine what the lesion is. Take, for example, a left hemiplegia with paralysis of the left cheek, arm, and leg. The patient may have a tumour, a patch of softening, a hæmorrhagic focus, a syphilitic formation; he may have what is exceedingly rare—local anæmia, and the only way of determining which one of these is present is by our knowledge of pathology. To this end we determine the temperature, pulse, and other symptoms; the conditions of the arteries; the presence or absence of the signs of degeneration throughout the body, and the presence or absence of the signs of contracted kidneys and heart disease. To determine with

certainly that a hæmorrhage has taken place in the brain, you must ascertain the previous diathesis and the general condition of the body. The rupture of vessels in the brain is a mere accident; the same statement may be made in regard to softening. This latter condition is often due to organic cardiac disease, producing embolism of a healthy cerebral artery, and sometimes, also, of arteries at the periphery, which are more difficult to make out. It is likewise caused by local obstructions in the arteries of the aged or prematurely old, and of syphilitic subjects. The same general rules apply to the study of diseases of the spinal cord. The nature of the lesion is to be determined by the pathological condition of the patient, and by means of empirical knowledge acquired by post-mortem examinations. For example, if a child presents with enlargement of the head and separation of the sutures, we know, as a matter of experience and post-mortem examination, that there is internal hydrocephalus, the most common cause of which is tubercle; and we also say that it is probable that the tubercle is compressing the aqueductus Sylvii. In the same way we determine the difference between syphilitic and non-syphilitic subjects.

I go on, now, to the diagnosis of the functional disorders of the nervous system. This subject does not admit of as systematic a presentation as the former. In many of the functional diseases of the nervous system, we know very little about their pathology, so we do not complete the third diagnosis; and as the disease is functional, we need not consider the second. For example, chorea is an obvious symptom which we can recognise at a glance. If we attempt to localise the lesion or disease, we cannot go any farther than to make the statement that a functional lesion is situated in the brain, and that it is very probably a cerebral affection. We make this statement upon the remarkable fact that the disease is often hemiplegiform. We cannot go any farther, and, as regards the lesion of chorea, we are entirely in the dark. We can only offer speculations based upon a few post-mortem examinations, which, in my opinion, are worth very little. The same is true of epilepsy, hysteria, and neuralgia. The best we can do is to state the symptoms definitely, and not attempt any rigorous diagnosis of the disorder, or try to determine the nature of the lesion, in the same sense as we do lesions in organic affections. But yet there is a diagnosis to be made of the nature of the lesion, or, as I would put it, the condition of the patient. This consists, after we have determined that the patient has chorea, epilepsy, or neuralgia, or "neurasthenia," of making an inquiry into his general condition, the state of the circulation, arterial tension, and, in some cases, the action of the heart, and the condition and mode of action of certain organs which we know, from empirical knowledge, to be connected with functional disorders. For example, within the last seven years we have learned, with great positiveness, that certain cases of headache are due to straining of the eyes. In studying cases of headache, especially cases of long standing, it is desirable—I may say imperatively necessary—to study the condition of the eyes. Thanks to the labours of Drs. Weir Mitchell and William Thomson, of Philadelphia, we have been able to relieve a large number of cases of "bad head," as I call them. In the same way, with reference to hysteria, we examine the patient, not simply for anæmia and mal-nutrition, but also for uterine and ovarian disease or vulvar irritation. This will lead us many times to a correct understanding of the case. There is quite a large class of cases in which the symptoms are nervous, the patients experiencing a curious depression, pain in the back and head, aching in the limbs, and many other symptoms, chiefly sensory, all of which we are generally unable to refer to any definite cause, and they are known under the name of "neurasthenia." This name is all very well, provided we go farther. One theory as to the cause of these symptoms—and it is held by some very respectable authorities—is that they are due to a variation in the amount of blood in the spinal cord and brain. I myself confess to very little faith in this view. I think it can be shown that there can be but slight changes in the

(a) Schroeder Van der Kolk: "On the Minute Structure and Functions of the Spinal Cord and Medulla Oblongata." Translation of the New Sydenham Society, pp. 6, 7. London. 1859.

amount of blood present in the spinal cord, and that these are not accompanied with symptoms. My own experience is that the symptoms are often produced by conditions of general mal-nutrition, which can be classified conveniently under the heads of lithæmia, or sub-oxidation of the tissues. Some other cases are due to weak eyes, some to ovarian diseases, some to the use of tobacco, sexual excesses, &c. Cases of so-called hyperæmia of the brain, now so fashionable, are to be studied in the same way from the standpoint of the general physician; nearly all such cases being, according to my experience, resolvable into instances of lithæmia, eye-strain, cardiac disease, renal disease, irritation from the sexual organs, &c., leaving exceedingly few cases of hyperæmia, if any. The diagnosis of lithæmia is to be obtained by the examination of the urine, and the usual method of doing this is very misleading. If the patient is told to bring a bottle of his urine, the first that is passed in the morning, it is found of high specific gravity, high colour, acts upon litmus paper forcibly, and may deposit urates; or the microscope shows, in a few hours, oxalate of lime. To judge in this way from one specimen, I believe to be a most superficial practice. I am not willing to say that a patient is a subject of lithæmia or oxaluria, unless I have examined specimens of urine on successive days, for the reason that the urine varies from day to day, and during each day, owing to the varying conditions of the body. One or two examinations are of very little help. In my practice I make a number of examinations—three or four—of urine passed morning, noon, evening, and at bed-time; and I am unwilling to use the term oxaluria unless I find this condition indicated by most of the specimens. By this means the average condition of the urine in twenty-four hours can be determined.

I will make a few remarks in regard to taking the history of a case. Very few medical men take good notes. It is a very difficult matter to write a history so that different medical men, reading it, would come to the same conclusion in regard to the case. Of course we first obtain the patient's story. We have to guide the patient, so that we can arrange the facts which he gives us in some logical order. It is desirable, in many cases, to give some illustration as to the behaviour of the patient, mental manifestations, &c. A few words with the friends of the patient, as to what they have observed, is often serviceable, and sometimes it is well to question the patient alone. In taking down the notes we form a dim mental outline of the diagnosis, in advance. It seems impossible to take a history without doing this. We next carefully record the objective symptoms presented by the patient, and thus reach what I have termed the first diagnosis. In some cases we may locate the lesion at once from the symptoms, and even determine the nature of the lesion. This is by no means infrequent, and the taking of the history will be the only time you need to give to the consideration of the case. In other instances you have to go on, step by step, and carefully determine the points in the diagnosis which I have referred to. We are often, in the course of this preliminary and semi-conscious notion of the nature of the case, led to doubt the patient's statements, and it is well to make a mental memorandum of these points, and, after the history is completed, question the patient again, or ask information of others. This is very necessary in cases where we investigate such causes as sexual irregularities and syphilis, family taints, &c.

TYPHOID fever may be said to be epidemic in Paris, 134 deaths having occurred there last week from this zymotic. The death-rate from other causes is normal.

In Providence, Rhode Island, with a population of 104,000, not a single death has occurred from small-pox since 1875. The reason is given as "general and careful vaccination."

ECTROTIC TREATMENT OF VARIOLES IN SMALL-POX—CAUTERISATION BY CARBOLIC ACID—WITH MORBID ANATOMY AND PATHOLOGY OF THE VARIOLES, AND GENERAL LOCAL TREATMENT. (a)

By MONTAGUE D. MAKUNA, L.R.C.P. Lond.,
M.R.C.S.,

Late Medical Superintendent of the Fulham Small-pox Hospital

(Concluded from page 304.)

Exclusion of Light from the Room of the Sick.—From the time of Rhazi up to the present day there have been advocates of darkened rooms in the treatment of small-pox, and as it is recommended by Dr. Ringer in his therapeutics, and still finds favour in the hands of some by way of experiment, I am compelled to take notice of it here. The Greeks, the Romans, and the other ancient races, made use of dark and sealed chambers, and Hindoo Vaydas and Arabian Hakims of the present day still recommend darkened cellars and underground chambers for the treatment of various febrile disorders, but no modern physician on either side of the Atlantic, or in the far East, ever dreams of perpetrating such a barbarity in their treatment, and yet we find in this enlightened age, with all the knowledge amassed on the influence of light and heat on life and animal economy by modern physicians, a few here and there will be found who will keep repeating experiments in this treatment of small-pox and torture their patients. After building lofty, airy, cheerful wards on sanitary principles for the promotion of the health growth of the patients, it sounds ridiculous to darken them at the expense of the ventilation. It is very nearly five years ago that Dr. A. Downes and Mr. J. B. Blunt laid their researches on the effect of light upon bacteria and other organisms before the Royal Society (Proceedings of the Royal Society of London. Vol. xxvi, page 488). These experiments have since been repeated by Professor Tyndall, confirming them (Report of the British Association, York, 1881). They have demonstrated that "Light is inimical to the development of bacteria and the microscopic fungi associated with putrefaction and decay; its action on the latter organisms being apparently less rapid than the former. Under favourable conditions it wholly prevents the development, but under less favourable it may only retard it. The preservative quality of light as might be expected, is most powerful in the direct solar rays, but can be demonstrated to exist in the ordinary diffused daylight, though it appears to be chiefly associated with the actinic rays of the sun." "A contagious fever (as small-pox is) may be defined as a conflict between the person smitten by it and a specific organism, which is multiplied at his expense, appropriating his air and moisture, disintegrating his tissues, or poisoning him by the decompositions incidental to its growth." From these scientific researches it is evident that to put a patient suffering from an infectious disorder in a darkened room is to lessen his chances of recovery, inasmuch as he is made to breathe noxious atmosphere, rendered more foul by darkness and at the expense of the ventilation. I cannot too strongly condemn the practice. (The light I have used in the treatment of my cases is the ordinary diffused daylight. Another reason that is urged for the use of darkened rooms is that ophthalmia in small-pox is prevented by darkness. My paper on "The Variolous Affections of the Eye," *Brit. Med. Jour.*, 3rd June, 1882, gives the results of my treatment of the cases in diffused daylight, and they can be very favourably compared with those who have used darkened rooms).

Nitrate of Silver.—It still finds favour with many, and I believe it is very frequently used without due con-

(a) Read before the Royal Medico-Chirurgical Society, 9th May, 1881.

sideration to its therapeutical value. It coagulates albumen as carbolic acid does. It is caustic, but its action is very superficial. It causes great disfigurement, blackening patient's faces, to their great horror, and creates unpleasantness among nurses and other persons surrounding them, while carbolic acid does not. Its application creates pain, its action is gradual and is attended with febrile symptoms and nervous exhaustion. In some cases it causes vesication. From this it is evident that its application cannot be beneficial. Ringer, Erasmus Wilson, Marson, Gregory, Curschmann, and a host of others recommend its use, but I am afraid they have very little to say in its favour. There are two plans for its use. Firstly, to open up the vesicles about the third or the fourth day of the eruption, and cauterise them individually. It is said to have been attended with success in the hands of Velpeau and Dr. F. Bowen. It might appear to some as impracticable, but the latter physician states he can trust his nurses with the application. Secondly, its lotion of the strength varying from 160 to 20 grains to an ounce of distilled water, is brushed over the surface of the skin. When so used, all the evil effects arising from it, and which I have enumerated above, are brought to the knowledge of the physician after a very short practice, and he is compelled to abandon it. It cauterises the epidermis without affecting the vesicles, and blackens the surface of the skin. Its astringent action causes condensation of the epidermis and the superficial capillary vessels. This serves as a sort of elastic covering on the skin, preventing the vesicles to rise on the surface. Under this mask the pustules advance unseen and unaltered. When the scabbing stage is over, the mask, in many cases, falls off *en masse*. From this it is evident that the good results claimed for it are apparent and not real.

Mercurial Preparations have fallen into disuse as they cause salivation, induce ischuria, and abortion in pregnant women. The only good result gained from their application is the relief from itchy sensations.

Iodine.—It is used by some, but its application is highly objectionable. As Dr. Ringer remarks, it has powerful chemical difficulties, and combines energetically with many organic or inorganic substances. It is volatile, and readily penetrates animal structures. Its application disfigures the skin only a shade less than the nitrate of silver. It is a rubefacient and caustic irritant, exciting inflammation, and causing blisters. Its application is attended with much pain. It is of no use as an ectrotic. I shall refer to its use further on when I consider the treatment during convalescence.

Cold Compresses.—They are recommended by Dr. Curschmann, and I believe they do some good. I have seen good results from the application of cold in the use of ice-bags on patient's forehead during delirium, and on other parts of the body to prevent internal hæmorrhages. It relieves pain and swelling, and cuts off the inflammatory processes; but is impracticable, expensive, and is objected to by the patients.

Gutta-percha.—Dr. Groves used a solution of gutta-percha in chloroform; and Dr. Stokes, of Dublin, used it in asthenic cases with success. The chances of pitting in asthenic cases are much less than in sthenic cases, as he himself remarks in his writings. The object of its application is to shut out the vesicles from light and air. Its use causes offensive smell from the pent up discharges. It cannot be looked upon as an ectrotic, and, as I have shown above, exclusion of light and air cannot prevent the processes of fermentation and germination, or of putrefaction.

Collodion as an ectrotic is of as much use as gutta-percha. The advantages claimed for it are transparency and cleanliness, enabling the operator to see what is passing beneath, and its contractility is said to disperse congestions. These properties can hardly attain the object in view.

Plasters and Ointments.—Ectrotics like carbolic acid, iodine, nitrate of silver, and mercurial preparations are

used in ointments and plasters, but such a mode of application is uncleanly, and renders the actions of the agents inert to a certain degree. Plasters cause contraction of the skin, and the good results therefrom are only apparent. A plaster of carbolic acid and shellac is used, but its action is gradual, and consequently its use as an ectrotic is not worth recommendation. Dr. Horatio Yates recommended the use of the carbolic acid ointment of the strength of two drachms to two ounces; and Dr. Watson, glycerine solution of the carbolic acid of the strength of twenty per cent. I think these preparations are too diluted to be of any use, and would not cauterise the varicoles.

3. *Remedies Used during the Pustular Stage to Prevent Further Disintegration of the Tissues*.—When this stage is reached we must give up every hope to prevent pitting, as the morbid anatomy of the varicoles tells us that the disintegrating processes of the structures of the skin have far advanced, and the structures of the corium are involved. The treatment now to be adopted is that of ordinary furunculæ or superficial abscesses. It consists in opening up the pustules and evacuating their contents: applications of warm linseed meal poultices, with carbolic oil spread over their surface to prevent their sticking to the skin. Three or four successions of poultices have the desired effect of emptying the pustules. When the discharges continue, the surface ought to be dusted over with absorbent powders, as equal parts of starch and oxide of zinc. When they cease I apply carbolic oil of the strength of one to twenty over the surface to check further suppuration and putrefaction. I never allow the scabs to be formed, or leave them long attached to the skin, as they cause ulceration and corrode the structures underneath, the natural sequence of chronic inflammatory processes.

4. *Treatment during Convalescence*.—In most cases little or no treatment is required at this stage. The remnants and sequelæ of varicoles are, maculæ, psoriatic condition of the skin, tubercles—especially over the face and near the nose—enlargement of the openings of the sebaceous glands, with hard, cheesy deposits in them, furunculæ, and ulcers.

Maculæ.—I never use any remedy to remove the staining of the skin, as all applications cause irritation and hyperæmia, with increased pigmentary deposit in it, which must retard, and not accelerate, their removal. (I have recently seen a lady using an astringent lotion of zinc and rose water for nearly three years for the removal of the staining of the skin, with the effect of roughening her complexion.)

Psoriatic Condition of the Skin.—When the scales are thin and easily removable, I use a preparation of white precipitate in glycerine (sixty grains to an ounce); but when the scales are thick and of the form of scabs, giving the appearance of local ichthiosis, I apply dilute nitrate of mercury ointment, accompanied with poultices, with good results.

Tubercles on the Face, &c.—When all the inflammation has ceased I apply iodine applications, to promote the absorption of the tubercles and remove the warty growths. When the tubercles are large surgical interference is necessary.

The Enlargement of the Openings of the Sebaceous Ducts.—It is best treated by the application of white precipitate or iodine ointment. I generally prefer the former.

Furunculæ and ulcers can be treated on general principles.

I have given here my experience and the practice I have followed out in the treatment of the cases at the Fulham Small-pox Hospital. The conclusions I draw from them are as follows:—

1. That ectrotics are useful only during the early stage of vesiculation.
2. That the cauterisation by carbolic acid is the best of them all; but when a case has advanced in the vesicular stage some good might be done by cutting

open the vesicles and applying a strong solution of carbolic acid.

3. That some good might be done by the caustic application of the nitrate of silver sticks to each vesicle after cutting them open, but the practice is attended with much pain and irritation.

4. That the practice of the exclusion of the ordinary daylight from the sick-rooms, especially at the expense of the ventilation, must be condemned. (It does not prevent the processes of germination, fermentation, or supuration.)

5. That during the pustular stage our efforts ought to be solely directed to the evacuation of the contents of the varicoles, relieve pain, and hasten the process of cicatrisation.

6. That, during the convalescence, the less the irritants are used to remove the roughness and maculæ on the skin the better.

Clinical Records.

THE MIDDLESEX HOSPITAL.

Stone in the Bladder—Bigelow's Operation—Recovery.

Under the care of Mr. HULKE, F.R.S.

[For the report of this case we are indebted to Mr. W. ROGER WILLIAMS, F.R.C.S., Surgical Registrar.]

THE patient, a married man, æt. 47, was admitted on March 8th, 1882, with the following history:—

Three years ago he said he had an attack of colic from which he soon recovered. A year later, during micturition, the stream suddenly stopped, and he had to lie down before he could again pass water. He has since been unable to micturate in the erect position, but he has never had complete retention. A few months later, after a long walk, he first noticed blood in his urine; he has since been subject to this after any exertion. Pain came on about this time, aggravated by motion, worse during and after micturition. In order to relieve himself in this process, he was accustomed, he said, to take a long piece of india-rubber tubing, which he generally filled with rain water from an open tank, then introducing one end of this into his urethra and the other into his mouth, he used to blow the contents into his bladder when lying down. Four months ago he passed some yellowish white gritty substance.

As a rule he has enjoyed good health. He has been a soldier for sixteen years, having served ten years in India. Twenty-three years ago he had syphilis, and three years later syphilis. He has only followed his present occupation as a painter for the last two years. He has been married eleven years. His mother's father, who was a native of Derbyshire, had stone in the bladder. Patient was born in Hanley, Staffordshire.

On admission he was well nourished and healthy-looking. He complained of the ordinary symptoms of stone in the bladder, together with great frequency of micturition—every half-hour during the day, and five or six times at night. Tongue, furred. Appetite, fairly good. Bowels, regular. Pulse, 70—small and weak. Urine abundant, turbid, and of milky appearance; sp. gr., 1025, alkaline; albumen, 1-4th; phosphates and muco-pus; no casts.

On sounding him Mr. Hulke readily detected a stone, which he seized in the lithotrite, and judged to be of large size. Owing to a stricture near the bulb there was a little difficulty in introducing the lithotrite.

After a week's rest in bed the frequency in micturition diminished very much, and albumen almost entirely disappeared from the urine.

On March 15th, the patient being anaesthetised, Mr. Hulke proceeded to crush the stone. A modification of Bigelow's lithotrite made by Weiss was used. It frequently became clogged, and had to be introduced several times. The debris was removed by Bigelow's aspirator. It consisted of a viscid phosphatic material, in which seed-like bodies were embedded. At the time it was thought probable these might have been introduced by his amateur method of injecting the bladder, as previously described. The operation lasted two hours, and was then terminated

in consequence of intervening irregularity of the heart's action—the operator being aware that some detritus still remained in the bladder.

March 16th.—Not much sleep last night. This morning frontal headache and hypogastric pain. For the latter a linseed poultice was applied. Temperature, 90°6; pulse, 76. Tongue, moist, furred. Micturates every hour; urine very turbid and ammoniacal, containing much gritty sediment. Bowels regular. During the day several good-sized fragments passed. In the course of the next few days the headache and hypogastric pain completely disappeared. The frequency of micturition also diminished, and the urine became clearer, though it still contained a considerable amount of phosphatic and muco-purulent deposit. Several fragments were passed.

22nd.—Occasionally passes small fragments. Urine, sp. gr., 1015, alkaline, phosphates, and muco-pus; bladder washed out daily with solution of sulphurous acid, 1 in 20.

24th.—No more fragments passed. Patient says he feels quite well. Sleeps well at night; seldom has to get up to micturate. No pain. Appetite good. Pulse, 74; temperature, normal. After this date improvement was very rapid, and he was soon able to leave his bed. The urine, however, still contained a large quantity of mucoid material.

He was discharged on April 5th in excellent health, having been sounded a few days before leaving the hospital, but nothing was detected.

In the beginning of July he wrote to say he continued well, and quite free from any urinary trouble.

Mr. Hulke submitted the seeds to Mr. Carruthers for examination, who kindly supplied the following report:—

"The seeds you gave me are those of the common holly. The berries were inserted whole, for you see a good deal of the fleshy substance of the fruit, and on one specimen I found the calyx lobes still adhering to the skin of the fruit."

Mr. Hulke remarked that the unusual clogging of the lithotrite might have been due to the presence of these berries, for in his boyhood the best bird-lime used to be made by their putrefactive maceration. Doubtless, he added, they were pushed down his urethra when drunk.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 13, 1882.

The President, PROFESSOR LISTER, in the Chair.

DR. THEODORE WILLIAMS communicated a

CASE OF PHTHISIS TREATED BY RESIDENCE AT HIGH ALTITUDES,

The patient having been exhibited at a former meeting of the Society. A medical man, æt. 30, had cough and expectoration of three years' standing, followed by hæmoptysis, wasting, elevation of temperature and great prostration, and when seen by Dr. Williams in consultation with Dr. Vircher Bindon August 30, 1881, presented the physical signs of consolidation of the upper lobe of the left lung. After five months residence at Davos, including a walking tour of seventeen days in the Engadine, during the whole of which period he took exercise largely, he gained one stone in weight, and found his strength and power of climbing greatly improved. On first arrival at Davos he had dyspnoea from the rarefaction of the air, but this passing off, his respiratory powers became greater than previously. On his return Dr. Williams found an increase in the crytometric and other chest measurements, especially in the upper regions of the thorax, and the physical signs denoted the development of emphysema and the old consolidation, and hypertrophy of the healthy lung. Dr. Williams stated that while he ascribed the general improvement of the patient to the dry pure antiseptic atmosphere and the sun's powerful influence, he assigned the arrest of the tubercular changes to the local effects on the lungs of breathing rarified air, which, by inducing emphysema, caused an expansion of the thorax, at the same time affording a barrier to the encroachment of further infective processes in the organs. With regard to the durability of the good results of mountain climates, Dr.

Williams's experience was that in well selected cases, one or two winters sufficed to produce permanent arrest of consumptive disease, though in many instances a prolonged stay of at least two years was desirable. Dr. Williams exhibited cytometric tracings of similar cases who had resided at Davos and Colorado for several months to illustrate the widening of the chest through breathing mountain air.

Dr. ALTHAUS said he could speak to the benefits conferred on a patient of his own by residence in Colorado, a young lady, *æt.* 20, whose condition was regarded as almost hopelessly unfavourable by several physicians in this country, but who experienced most wonderful improvement under the influence of the Colorado climate, which deserved to be generally regarded by the profession in relation to phthisical patients. The climates ordinarily recommended in such cases, he thought, only retarded the progress of the disease for a time, but in the case referred to the improvement was both very marked and quite permanent. The great advantage of the Colorado climate was its equality at different seasons, thus obviating the necessity for removal of patients to lower levels at times, as must be done in most other situations. It was also remarkably dry, so that a sponge wrung out from a bath would be perfectly dry within five minutes if left exposed in the air; and no dew fell in the country; conditions to which much of the familiar advantages it possessed might be attributed.

Dr. BROADBENT inquired whether it could be asserted from study of a large number of cases, that results obtained from wintering in Davos were superior to those obtained elsewhere. Conclusions drawn from a single case could, he thought, hardly be satisfactory. Moreover, sedentary patients who resorted to exercise might be expected, under it, to improve in any climate; and he would like to hear whether Dr. Williams considered his case to prove the superiority of Davos over other health resorts.

Dr. MACLAGAN put the question whether high latitudes or absence of atmospheric germs most determined the effects observed. The thoracic expansion referred to might, he considered, be expected to take place in any one, not necessarily phthisical, who lived for a time at a great altitude.

The PRESIDENT took occasion to correct the error fallen into by Dr. Williams in speaking of an aseptic atmosphere as being *anti-septic*. The advantage of the atmospheres described might, he thought, lie in their being dustless, and although it was to be assumed that germs already existing in the lung would continue to develop, the non-continuance of infective processes as described by Dr. Williams might be dependent on this state of the air. He had recently experienced, in Switzerland, the unsatisfied desire for long breaths referred to in the paper, and it was clear that a continuance of this condition for a length of time would necessitate enlargement of the chest capacity. He had seen a gentleman who declared that residence in a high region so invigorated him that he was really astonished at the effects produced. The influences thus brought into play were distinctly beneficial, but why, could not now be declared.

Dr. WILBERFORCE SMITH urged the need for guarding against fallacy introduced by omitting to allow for mere increase in thickness of the walls when determining chest enlargement under treatment. He thought also that it was admitted the phthisical state was maintained by inter-current attacks of slight inflammation.

Dr. WILLIAMS explained that, having treated the general question of high altitude for phthisis in a previous paper, he had purposely confined his present communication to a single case. He was quite agreed as to the advantages of Colorado, but it was too far distant for the majority of patients to proceed to it. The object of his paper was to demonstrate the benefits of mountain climates, as shown by the enlargement of his patient's chest, and the change from lung dulness to even hyper-resonance, consequences which, as far as he knew, had not been noted by any other writer. He admitted that improvement might follow the adoption of ordinary hygienic rules of life, and was unable to explain the precise influence exercised on cases of phthisis by a germless atmosphere. A complete and accurate analysis of the air from these regions had never been obtained. He could not but think the chest expansion and permanent improvement in breathing experienced by his patient a great advantage, and there was abundant testimony to show that residents in high climates do possess unusually capacious lungs, which confer great advantages on them. He could not pretend to say what was the influence

exerted on tubercle bacillus by mountain air. Inter-current inflammation was not at all less frequent at Davos and similar places than elsewhere at lower levels; high altitudes apparently did nothing to diminish the liability of the patient in this respect.

EPITHELIOMATOUS TONSIL—EXCISION.

Mr. GOLDING BIRD detailed a case in which he had removed an Epitheliomatous Tonsil in the manner adopted by Cheever, 1871, and referred to three other cases of the same disease in which he had determined not to operate. The operation consisted in an external incision from the ear to the hyoid bone, through which the wall of the pharynx was reached with the greatest ease, and the tonsil with the adjacent pharyngeal tissue removed with the galvanic cautery. The later steps of the operation were aided by an additional incision through the cheek from the angle of the mouth. The disease having also affected the tongue, part of that organ was removed, as well as an enlarged gland at the angle of the jaw. Until the wound closed an *oesophagus* tube was used for feeding. Although great relief was given to the patient, yet he soon succumbed to recurrence, not in the site of the excised organ, but in the tongue and the lymphatics of the neck. The conclusions arrived at by the author were that where only a limited infection of the lymphatic glands existed and where the faucial growth was circumscribed, or nearly so, operation was called for, but that in other cases feeding with tubes with subsequent gastrostomy was the treatment. The operation was itself far easier than many of daily occurrence, and seemed to offer no special risk to the patient. Of the four cases mentioned it was considered by Mr. Golding Bird that in three the disease was primarily in the tonsil, in all four it was the left side that suffered.

Mr. CLEMENT LUCAS related a case of

EXCISION OF THE BASE OF THE TONGUE, RIGHT TONSIL, AND PART OF THE LEFT PALATE FOR EPITHELIOMA: ANEURISM OF BOTH POPLITEAL ARTERIES,

of which the following are particulars:—

D. K., *æt.* 64, a coal porter on the riverside, who had drunk freely, first came under Mr. Lucas's care in Guy's Hospital on February 13th, 1880. He was at that time suffering from a large aneurism of the right popliteal artery causing pain, and oedema of the leg and foot, and from a smaller aneurism of the left popliteal. Digital compression of the right femoral artery was commenced on February 17th, and continued for sixteen hours, when the aneurism appeared to have consolidated, and pulsation could no longer be detected. On the following day some pulsation was re-established, and on the 20th, digital compression was again commenced, and continued for eleven and a half hours, when pulsation ceased and did not recur, the tumour afterwards gradually shrinking. An attempt was made about a fortnight later to cure the small aneurism in the left popliteal space by digital compression, but this failed, and as the tumour caused him little inconvenience, no further treatment was suggested, and he left the hospital. He was re-admitted on August 2nd, 1881, suffering from epithelioma of the base of the tongue and right tonsil. On the right side of the tongue, opposite last molar tooth, was a small ulcer, grey in colour, and irregular on the surface. The ulceration extended along the anterior pillar of the fauces, and involved the right tonsil, as well as the tissue between the tongue and the jaw. The surface of the tongue near the base was raised and indurated for about half an inch from the margin of the ulcer. The movements of his tongue were interfered with, so that mastication and deglutition were painful, and there was an increase of salivary secretion. No enlarged glands were felt beneath or behind the jaw. The operation was performed on August 9th. The patient being placed under the influence of chloroform, the cheek was first divided by an incision from the angle of the mouth to the masseter muscle, and the facial artery was twisted. A gag was then inserted on the left side of the mouth whilst the tongue was drawn forward with forceps and the flaps of the cheek were held back by retractors. The back of the tongue and tonsil are in this way easily reached. The soft palate was next divided near the middle line by means of Paquelin's cautery, and dissected down with the anterior pillar and the tonsil. Attention was now paid to the tongue which was divided in the median line with a scalpel, and carefully dissected outwards till the lingual artery was reached. This was seized with two pairs of torsion forceps, divided

between, and the ends twisted without loss of blood. The tissue between the tongue and jaw was next dissected up, the cautery being used to stop any bleeding points, and finally the growth, with the base of the tongue, right tonsil, and half the soft palate, was removed in one mass. The cheek was brought together with three hare-lip pins, and it united primarily. The patient recovered rapidly after the operation, and sixteen days later was again subjected to digital compression for the cure of the left popliteal aneurism, which was about the size of a pigeon's egg. Pressure was kept up with the aid of opium for forty-eight hours, but soon after this, though much consolidated, the tumour still pulsated. He left the hospital, with the tongue quite healed, on September 16th. He was re-admitted into the hospital on February 13th, 1882. There was no return of the disease in the tongue or palate, which were united by a firm and sound cicatrix. There was a large mass on the right side of his neck below and behind the jaw, which commenced six weeks before, and grew rapidly, extending outward; beneath the sterno-mastoid. An operation for the removal of this growth was undertaken on the following day. A vertical incision about four inches in length was made, commencing behind the jaw, and the growth dissected round. It was found necessary afterwards to enlarge the wound transversely. In the course of the operation the lower part of the parotid gland, a portion of the sterno-mastoid, the posterior belly of the digastric and stylo-hyoid, and a portion of the submaxillary gland were removed, all of which were infiltrated. The facial artery was twisted, and the facial and lingual veins ligatured with catgut. At the bottom of the wound the internal jugular vein and the two carotids, with the hypoglossal nerve, were exposed. Two enlarged glands were also removed from beneath the sterno-mastoid. The patient recovered without a bad symptom, and left the hospital on March 24th. He was again seen in July last with a recurrence of the growth on both sides of the neck, but there was still no sign of disease in the original site. It was not then thought advisable to interfere further. Mr. Lucas said that by the operation described it was evident a cancerous tonsil, with the adjacent structures, can be completely removed from within the mouth, and when this is practicable, it has the advantage over the external operation of avoiding the fistulous track, through which saliva is apt to ooze. For the rest the treatment of cancer here does not differ from the treatment of it elsewhere. The treatment—and the only treatment—is to operate early, and to operate late; to operate, indeed, so long as it is possible to remove a loathsome outgrowth without great immediate danger; to operate to keep it local; to operate on the earliest return; and though we may often be disappointed in our attempts to eradicate the disease, we may still prolong life, or, as in the case before us, succeed in driving the disease from its original site to one where it is less offensive, and more easy for the patient to bear.

Mr. C. HEATH observed that Cheevers, who originally devised the difficult operation for removing the tonsil from without, was himself doubtful as to its value. He (Mr. Heath) thought all would agree as to the advisability of operating as often as required to remove the disease; and that glands should, if enlarged and easily movable, be taken away; and thus a chance offered both to prolong life and change the site of disease. He knew a contrary opinion was even yet entertained by some surgeons.

Mr. MORRANT BAKER asked if much trouble had been experienced in the final steps of Mr. Lucas's operation. He imagined the *écraseur* might be dispensed with before the end of the operation. He agreed as to the necessity for complete extirpation of diseased glands; but respecting the so-called changed site of disease, he thought it must be assumed that its seeds were present in the new position where it subsequently appeared.

Mr. BUTLIN did not regard operation in such cases of cancer as offering hope of successful results. He imagined there might be an error respecting the malignant nature of the growths removed where a permanent cure was supposed to have been obtained.

The PRESIDENT characterised the operations described in the papers as bold and skilful. It might be a question how far in such cases advantages were secured by operation. In one instance, interference certainly did not so result; but Mr. Lucas's case offered an example exceptionally favourable. Further details as to the method of removal,

&c., would be interesting. It was satisfactory that surgeons were generally agreed on the advisability of removing accessible glands of which the condition admitted, and suggested, such proceeding. Mr. Lister remembered that a different opinion was held during his student life, and he believed he himself was the first to clear out of an axilla the mass of diseased glands it held. He certainly had much reason to be pleased with the success which had followed in many such cases. He recollected that Mr. Syme had once removed a single lymphatic gland from under the chin of a patient with cancer of the lip, and with good results following. Was Mr. Golding Bird inclined to desist from operation in future cases?

Mr. GOLDING BIRD said he was in favour of not operating again, but in future treatment of such cases to feed by means of a tube as long as possible, and finally resort to gastrotomy.

Mr. LUCAS felt himself in accord with Mr. Heath and the general opinion as to advisability of operation. He divided the tongue with the knife entirely. He failed to agree with the gloomy opinion expressed by Mr. Butlin.

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

THE IMPERIAL GERMAN CONGRESS OF SURGERY.

My previous account concluded with the discussion on Lungenbeck's paper on "Iodoform in the Treatment of Wounds." This was followed by a paper by Herr Braun, of Heidelberg, entitled—

CONTRIBUTIONS TO THE STUDY OF STRUMA MALIGNA, based on the careful and accurate autopsies of 20 cases of neoplasm of the thyroid. These showed that not unfrequently the trachea and œsophagus are so completely surrounded by the new growth and embedded in it that only too easily wounds of the trachea or œsophagus may be inflicted during the attempt to remove these diseased structures. In a series of 72 accurately recorded cases such an unfortunate occurrence actually took place 22 times. In reply to Herr Lungenbeck the author stated that sarcoma and carcinoma had been observed in about equal proportions. Gussenbauer recommended early operation. Herr Lungenbeck said that in most of the cases observed by him removal was quite impossible, owing to attachment to the great vessels, otherwise there would have been no difficulty.

RADICAL CURE OF HERNIA.—Herr Schwalbe (Magdeburg) followed with a paper on the above. His method consisted in the injection of alcohol into the neighbourhood of the hernial aperture. He had had 84 cases within a recent period, and in every instance had succeeded in closing the aperture, so that a truss could be dispensed with. Herr Ranke (Groningen) had made use of the method described in over 100 cases, and had ascertained that by means of it a cicatrix could be produced at the hernial site and without danger. In recent cases and young children he had seen good results, but would hazard no opinion as to the ultimate issue. Herr Gussenbauer confessed that, according to his observations, the method was (1) absolutely safe, and (2) that within the space of six to eight weeks diminution in size of large hernial apertures could be brought about, so that intestine no longer protruded. The method was worthy of further trial.

THE TRANSPLANTATION OF MUSCLE IN HUMAN BEINGS.—Herr Helferich (Munich) then read a paper on this subject, based on a case in which the whole of the biceps of a woman had been removed with the exception of a strip the thickness of a lead pencil, and replaced by a piece of muscle from a dog. Complete healing took place and after some months' use of electricity the power of movement lost previously to the

operation was restored. Herr Gluck (Berlin) reported that his experiments in the transplantation of muscle had always given positive results.

OPERATION FOR ECHINOCOCCI IN THE ABDOMINAL CAVITY.

—This paper was read by Herr Landau (Berlin). He alluded to the fact that the subject had already been discussed on two previous occasions by the Congress, without, however, any definite decision thereupon. It seemed to him to be the ruling belief that the disease was an unattackable one, notwithstanding that treatment by operation had shown results that were exceedingly favourable. At the last Congress Volkmann's method of operation was generally recommended. There were, however, great drawbacks to this plan, and he (the speaker) had decided to return to a more simple mode of operation—a mode that had been first systematically practised and recommended by Säger (Groningen) and Lindemann of Hanover. The plan followed and slightly modified by the speaker was as follows: After the cyst has been cut down upon and the peritoneum opened, the cyst being still unopened, the echinococcus is secured by vertical sutures placed in the angles of the wound. The threads are not tied, but simply held on the stretch by assistants. By this manoeuvre the overflow of fluid is rendered impossible. The cyst, which now as a rule protrudes, is punctured by a Dieulafoy aspirator. It is then incised longitudinally, and emptied. The edges of the cyst are then completely everted and fastened by numerous sutures to the abdominal wall; the wound remains open and is drained. He remarked, in conclusion, that from 4 to 5 weeks after operation a profuse secretion of bile usually took place, which, however, was of no pathological significance, and was simply synchronous with the exfoliation of the echinococcus sack, and the consequent freeing of the bile channels. Another and somewhat disagreeable occurrence incidental to these cases was the development of an intense garlicky odour, not dependent in any way on diffusion of intestinal gases. It was worthy of note that the point selected for operation should not be that which was most prominent, but that which was nearest the ribs. He then exhibited two cases that had been operated on by himself—one a girl of 13, and another of 8 years of age. In the latter two echinococci, one in the axillary and the other in the sternal line, which, however, were not in communication with each other, were removed by the one operation. The wounds closed in about 14 days. Herr Küster, of Berlin, in opposition to his own former views, had operated in the way described by Herr Landau, and had been fully satisfied with the results. He did not consider, however, that the fibrous cyst should be cast off by purulent granulation. If the course of events was aseptic, the discharge of bile was absent, so was also the garlicky odour, whilst the cavity gradually contracted, and became filled up by granulations, which finally formed a firm cicatrix. Herr Thiersch also confirmed the statement of the previous speaker, that in aseptic cases the disagreeable odour was not present.

ON OPERATIONS ON THE BLADDER, WITH SPECIAL REFERENCE TO ITS EXTIRPATION IN ECTOPIA VESICÆ.—Herr Sonnenburg then read this paper, and exhibited a case that had been operated on. In the discussion that followed Herren Thiersch, Bilroth, and Langenbuch (Berlin) took part.

FIXATION OF WANDERING KIDNEY BY OPERATION.—Dr. E. Hahn (Berlin) then read this paper, and exhibited a patient. In the patient presented the left kidney had been fixed nine months and the right four, by the method published by the author, with the result that the patient could get about, which before, with her colossal movable kidney, was impossible. It was not a difficult matter to fix the kidney with certainty. When the covering was drawn out

through the wound it could be fixed in the manner recommended by Simon. In the discussion that followed Herr Landau (Berlin) said that his experience led to the belief that operative treatment was not only impracticable, but positively injurious, for the reasons that, as the case exhibited showed, the kidneys would not be fixed in their normal position. Disturbance in the circulation of the organs would be set up, and the excretion of urine would be interfered with, inasmuch as the ureters would be put on the stretch. Then the patient, if a female, might become pregnant. The connection between the kidneys and genital organs was not an unimportant one, as post-mortems, for example, those of Virchow, had shown. In prolapse of the uterus the kidneys and ureters were dragged upon, and if the kidneys did not follow the line of traction the ureters would be compressed, and hydronephrosis would be the result. Herr Küster had operated once with benefit to the patient. Herr Esmarch could relate a similar experience. In a case in which the wound had healed by granulation the complaint ceased. Herr Hahn replied. He did not operate till all other treatment—by bandage, &c.—had failed.

A CASE OF SUCCESSFUL RESECTION OF STOMACH ON ACCOUNT OF GASTRIC ULCER.—Herr Rydiger (Culm) exhibited the foregoing, with preparation.

The operation was performed on the 21st November, 1881, on account of an occluding ulcer of the stomach, in consequence of which enormous dilatation of the organ was produced. Every second day pyrexial disturbances occurred in consequence of retained decomposing food. The speaker held that the operation was far more frequently indicated for stenosing ulcus ventriculi than for carcinoma of the stomach. In the discussion that followed Herr E. Hahn (Berlin) thought that the condition of the colon and its contents appeared to have a more important influence over the operation than was generally supposed. In a case in which he had recently operated for dilatation in a patient sixty-three years of age, and in which the patient died on the eighth day, absolutely without any symptoms of fever or reaction, but with persistent fecal vomiting, the cause appeared to lie in the loaded condition of the colon. Large quantities of feces had been evacuated by enemata previous to the operation, and yet at the autopsy the colon was found to be loaded. Herr v. Langenbeck had performed resection of the pylorus in a case with attached pancreas, but the patient died of collapse before the completion of the operation. Herr Bilroth said he was very much surprised at the great number of resections of the pylorus that had been undertaken in so short a time. He himself had waited five years before meeting with a case that seemed suitable for the operation, and in this case the diagnosis was wrong. The tumour proved to be a lymphoma of the mesentery, and he simply closed the wound. With the very greatest care in the selection of cases, those suitable for resection would be but rarely met with, and one should never be afraid to desist from proceeding with the operation if during its course the extirpation should seem unusually hazardous. He held as particularly dangerous the excision of the pancreas, but he did not believe that the contents of the intestines would have any influence on well-placed sutures. In every gastro- and enterography the sutures should be so accurately adjusted that there could be no possibility of intestinal contents coming into contact with the wound. Silk, and not catgut, should be employed, and the lumen should not be too much encroached upon. But above all, he would warn them not to carry the resection too far. If the infiltration extended too far forwards the operation would be in vain, and it was for this reason that the number of cases suited for the operation was so very small. He held with Leube, that the non-cancerous strictures of the pylorus, as well as cases of di-

lation, were much more suitable for resection; for if the disease were only moderately widely spread, the case would end fatally, as mechanical difficulties invariably cropped up. Herr Gussenbauer (Prague) mentioned a case of resection of the pylorus undertaken on account of a movable tumour in the neighbourhood. The case ended fatally. He also was of opinion that the best indication for operation was a non-carcinomatous stricture.

SUTURE OF THE BLADDER.—This (the last paper) was then read by Herr Juillard (Geneva). Whilst removing an ovarian tumour, very firmly adherent to the bladder, the posterior vesical wall was rent for a space of 12 cm. (4½ in.), and the edges of the wound gaped widely. There was not the slightest bleeding, a phenomenon that led to the supposition that the structure of the wall had undergone fatty degeneration from pressure of the tumour. Herr Juillard then united the edges of the wound by fifteen catgut sutures, 1 cm. apart. He took special care to leave the serous coverings in contact throughout. The result was extremely favourable. Herr Esmarch had met with a similar case in which he had closed the rent with silk, and inserted a retaining catheter. Result favourable. Herr Billroth related a case of extensive rupture of bladder in consequence of the firm attachment of an ovarian cyst. In the further course of the operation the intestine was also torn. These accidents necessitated both resection of intestine and enteroraphy. No catheter was left in, but for the first three days the urine was withdrawn frequently. The result was favourable, the patient being well in three weeks.

Department of Lunacy.

LADY COMPANIONS FOR THE INSANE.

DR. REES PHILIPPS, in his reports on the Wonford Lunatic Hospital for the Insane at Exeter, strongly advocates the appointment of educated ladies as companions to the inmates of the female departments of asylums for lunatics of the upper and middle classes. Every hour that he spends in the female wards of the hospital under his charge strengthens his conviction of the beneficial influence on lady patients of kindly companionship and the nursing of gentlewomen. A certain proportion of lady nurses has been introduced into that admirably-conducted registered hospital—Barnwood House—at Gloucester, and the medical superintendent, Dr. Needham, is satisfied that he obtains more work from these lady-nurses, and at no increased cost, than from nurses drawn from the domestic servant class. If this opening for useful and meritorious work was more widely known than it is at present, many gentlewomen, of suitable position and temperament, would doubtless avail themselves of it. The emoluments offered are not large; but an honourable livelihood and interesting occupation are not without their attractions.

THE CRICHTON ROYAL INSTITUTION.

A STRIKING and commendable feature in Scotch lunatic asylums has always been the attention paid in them to the moral treatment of their inmates; and of all Scotch lunatic asylums, the Crichton Institution has invariably held the first place in this branch of treatment—a distinguished position, which it seems in no danger of forfeiting, under the direction of its recently-appointed medical superintendent, Dr. James Adam. In the annual report of the institution which has just been issued a long and varied list is given of the occupations and recreations provided for the

patients, comprising Christmas-tree festivities, with distribution of gifts to each resident, meetings of the Literary Society, theatricals, readings, conjuring performances, lectures, flower shows, balls, concerts, glee parties, tea parties, foot-ball and cricket matches, bowling and lawn tennis tournaments, &c. The advantage of the mental diversions from morbid currents of thought thus provided is to be seen in the large proportion of recoveries recorded in the Crichton Institution, amounting to upwards of 50 per cent. of the admissions; and one possible evil of too exclusive and absorbing a study of moral treatment is to be recognised in the fact that Dr. Adam, while expatiating at length on amusements, has not a word to say about the service done by drugs and medical agents. True progress is only possible when medical and moral treatment walk hand-in-hand. Either of these attempting to walk alone soon stumbles and grows lame.

NEW PAUPER LUNATIC ASYLUM FOR ABERDEEN.

AT the last meeting of the St. Nicholas Parochial Board, Aberdeen, a report was adopted recommending that, subject to the approval of the Board of Supervision, the Board of Lunacy, and the ratepayers of the parish, a lunatic asylum, sufficient to meet the requirements of the parish, capable of containing 250 to 300 inmates, should be constructed at a cost of £12,000 to £15,000. There are six parishes in Scotland that possess lunatic asylums of their own, and, from the information received regarding these by the Committee, it appears that the cost of maintaining pauper lunatics in parochial asylums is about £22 per annum; while the St. Nicholas Parochial Board pays £26 10s. per annum for each patient kept in the Aberdeen Royal Lunatic Asylum. The number of lunatics chargeable to the St. Nicholas Parochial Board is at present 179—double what it was ten years ago—and the increase is still going on at a rapid rate.

THIS evening (Wednesday) the anniversary service of the Guild of St. Luke the Physician will be held in St. Paul's Cathedral, at 8 o'clock. Seats under the dome will be reserved for members of the profession.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Halifax 12; Bristol, Huddersfield, Norwich 14; Bradford, Plymouth, Cardiff, Salford 15; Derby 16; Portsmouth, Hull 17; Bolton, Brighton, Edinburgh 18; London, Dublin, Nottingham 19; Newcastle-on-Tyne, Leicester, Birmingham 20; Leeds, Liverpool, Sheffield 22; Preston 23; Glasgow, Wolverhampton 24; Oldham 25; Manchester 26; Blackburn, Birkenhead 27; Sunderland 32.

THE mortality last week from diseases of the zymotic class in the large towns was still below the average, except in Sunderland, where it was excessive. From scarlet fever, the highest death-rates were 2·2 in Sunderland and 1·6 in Sheffield: from measles, 4·8 in Sunderland and 1·2 in Birkenhead; from whooping-cough, 1·5 in Blackburn; from fever, 1·3 in Sunderland and 1·2 in Portsmouth; and from diarrhoea, 4·4 in Blackburn and 4·3 in Preston. The 40 deaths from diphtheria included 22 in London, 7 in Glasgow, 3 in Edinburgh and Leeds. Small-pox caused 4 deaths in London and its outer ring of suburban districts, one in Birmingham, one in Liverpool, one in Hull, and one in Newcastle-upon-Tyne.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 18, 1882.

THE CASE STATED AGAINST THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES BY THE ATTENDING PHYSICIAN.—No. III.

CONCEALMENT of infectious disease, and consequent dissemination of the infection, are, in the abstract—as we endeavoured to show in our last issue—the natural results of the inconveniences and pecuniary losses accruing to the custodian of the patient from the precautionary step taken by the sanitary authority to stamp out the disease. We fully recognise the propriety of those precautionary steps, but the fact remains that the publicity which necessarily attends the intervention of the sanitary authority and its myrmidons of the whitewash and chloride of lime operate distinctly as encouragements to the custodian of the patient to conceal the disease. We pointed out that the only existing counterfoil to this influence is the advice voluntarily given by the attending physician; that any arrangement which would encourage the custodian of the patient to call in the doctor at the earliest moment is, therefore, beneficial; and that the proposal to compel the physician to act as agent for the sanitary authority, and in such capacity to invoke the intervention of the whitewashers, would prove disastrous. The force of this argument depends in great degree upon the amount of the penalties of sanitation, by which term we mean the amount of inconvenience and loss which precautionary sanitation imposes upon the householder. If the sequences of notification were less to be feared than the results of concealment, no disease would ever be kept

secret; but the more tightly the sanitary line is drawn, the more thorough the medical officer of health is in following up and stamping out the disease by disinfection, isolation, and removal to hospital, the greater is the inducement on the part of the householder to keep the disease hidden and to keep the physician away, if the law should unwisely make him the agent of the dreaded sanitation. For this reason it is important to see to what lengths sanitarians will go in their zeal for stamping out, forgetting that strong measures in this direction are immediately productive of the concealment to which we have referred.

Let us first take the law as it stands. The Public Health (Ireland) Act, sec. 137, declares, where the sanitary authority, in case it "is of opinion on the certificate of its sanitary officer, or of any legally qualified medical practitioner, that the cleansing or disinfecting . . . would tend to prevent or check infectious disease, it *shall be the duty* of such authority"—

- To enforce cleansing and disinfection, or a fine of 40s.
- To seize and destroy all bedding, clothing, &c., which they deem infected.
- To remove forcibly to a suitable hospital "any person who is suffering from any dangerous infectious disorder, and is without proper lodging or accommodation," and to punish by a fine of £10 any one who obstructs such removal.
- To punish with a fine of £5 any one who exposes himself or any other person, if infected, in any public place whatsoever, or who "gives, sells, lends, transmits, or exposes" any infected clothes, bedding, or other material, or who exposes any infected dead body in any way whatsoever.
- To impose a fine of £20 on any one who hires to any one an infected house, or even a single room in such a house until it has been properly disinfected under the orders of a medical man.
- To punish with a fine of 40s. every person who sends a child to school within three months of its contact with infectious disease, even if it has only resided in a house in which such disease has been.

This is the law as it stands, and it might reasonably be said to be fully sufficient for dealing with any outbreak of infection; and so it would be if due vigilance and care were exercised by the officers of sanitary authorities to trace the infected cases as they occur. But these stringent enactments are the mildest, rose-water remedies in comparison to the legal burthens which the compulsionists would put upon the community. Some of the vagaries of the sanitarians are truly astounding. At the last meeting of the Social Science Congress the seconder of a resolution in favour of compulsory notification eulogised a system which, he said, was in operation in some foreign lands, under which the unhappy victim who happened to have a case of infectious disease in his house found, the moment he had notified its existence, that the civic sanitarians pasted across his hall door a yellow placard, which it was imprisonment for him to remove, and followed up the proceeding by putting a notice at the street entrance, warning all the world against entering therein. Another medical officer of health spoke rapturously of an American arrangement, by means of which—the instant the occurrence of a case of infection is known—sixty facsimile advertisements of the full particulars were transmitted by next post to the sixty public schools within the bailiwick.

But those who are willing to stop short of this perfection of compulsory notification will find provisions nearly as tyrannical in any of the Bills recently promoted for

towns in England. To take an example, I find that in Salford a Bill is promoted which gives the Corporation power—

a. To close peremptorily any school, shop, place of entertainment, or of public resort whatsoever, if it happens to be even situated in a neighbourhood in which an infected case exists.

b. To prohibit, under penalty of imprisonment, every person who resides in a house in which an infected case has existed, from either working at any indoor occupation, or from going out to work in any other place in same room with healthy persons.

To suffer imprisonment for a breach of this law one need not have been infected, nor even in contact with an infected person, and no amount of cleansing or disinfection of the person would entitle him or her to pursue his or her daily work.

In the name of common sense, we ask, does not compulsory notification under such a law as this mean temporary ruin to the unfortunate father of an infected child? Suppose him the proprietor of a small shop, or public-house, managed by himself, how is his business to go on if he is liable to have the house peremptorily closed and himself fined for mixing with his customers? Suppose him the manager of a hotel or lodging-house, how is he to keep it open if all its inmates are to be forbidden to go in or out? Suppose he is an artisan, how is he to live if neither he nor any of his family are to be permitted either to work at home at their trade or to go out to the factory or workshop?

We insist that law of this sort, if enforced (and if not enforced it is a farce), must make needful sanitation a terror to the victim of infectious disease, and must inevitably lead a large section of the public to conceal disease, and we contend that it is most unjust that the physician should be made, against his will, the agent for imposing these terrors on his patient, and most unwise that by such means he should come to be habitually excluded from the early treatment of infected patients.

(To be continued.)

CREMATION.

WITHIN the last few days the question of cremation in connection with the disposal of dead bodies has once more been brought prominently into notice, through publication of the fact that the process had been carried out in two instances in this country. The circumstances are of interest, both as showing the existence of a feeling favourable to this method of avoiding the dangers of grave-yard burial, and as indicating the difficulties under which cremation has at present to be performed.

The scene of the operations referred to was a private park in Dorsetshire, and the bodies those of two ladies who, dying in 1876, had each expressed a wish that she might be cremated rather than buried. We are informed that the arrangements were conducted in the simplest and most inexpensive manner consistent with efficiency, and that absolutely no unpleasantness was created by the burning, even to the senses of persons standing within a couple of feet of the furnace. Combustion was carried out in an apparatus constructed of fire-brick and iron plates, on which latter the bodies were placed, enclosed in elm shells and leaden coffins, these having been pro-

vided for their reception at the time of death. The coffins, lead and all, were placed in the furnace on the plates, which allowed the flames to play freely up, but prevented the ashes from falling into the furnace below. Thus the shells had to be consumed before the bodies, compelling the use of greater heat and longer time than usual, so adding another obstacle. The lead soon ran through the furnace into the ash-pits, and the white flames played round the strong elm shell until that fell at white heat over the body, of which about one hour afterwards only the ashes remained.

It is quite possible that these cremations may give rise to controversy respecting their legality, and as full details, illustrated by drawings of the furnace, &c., are promised in a few weeks, the question is certain to be re-submitted for discussion. It is quite certain that the sympathies of all sanitary authorities will be enlisted in defence of the practice as much as they have ever been, but it is none the less desirable that, whatever may eventually occur as a consequence of renewed consideration of this important subject, there should be displayed as much temperateness and good feeling as hitherto. There are undoubtedly large numbers of persons who cannot view dispassionately any proposal to depart from long-accustomed usage in dealing with the dead; they are animated, moreover, by sentiments which urgently demand the respect of those who are as strongly influenced as themselves, but in an opposite direction; and we cannot help a certain assurance that hope of a future adjustment of the law to sanitary requirements can only be entertained so long as the claimants for reform are content to adopt moderate and legitimate methods in seeking to attain their aim. Unmistakable prejudices do exist, and cannot be removed, either by ridicule or by an appeal to force; and from one, and that not the least important point of view, such prejudices are fully as deserving of attention and consideration as the purely scientific inspirations of cremationists.

We venture on these observations now, lest it should occur to any one to suggest that a time has come to enforce adoption of cremation in this country. However numerous may be the ranks of those who might be inclined to make this demand, they are still but a small minority of the population; but it may very justly be asserted, notwithstanding, that they form, both numerically and from the positions held by them individually, a body whose opinions should be carefully weighed in any determinate dealing with the question they are so much interested in. The principal object sought to be gained by the large association of medical and scientific men who some two years ago addressed a memorial to the Home Secretary praying for the legalisation of cremation is such as, if fully understood by opponents of this process, would at least secure their passive acquiescence. Not one person of all who signed the document would wish for, or seek to enforce, compulsory adoption of cremation; their sole wish is that legislative sanction shall be given to its performance whenever it has been desired by or on behalf of the dead; and experience has amply demonstrated that a high appreciation of its advantages is growing in the minds of the people.

At the present time, if not actually illegal in this country, cremation needs only to be exalted into a burn-

ing question to so excite public feeling against it that the passage of a law rendering it a penal act to carry it out in any case on a British subject, might be easily hurried through Parliament. We do not complain of this, because we are assured it is a natural consequence to be expected from the existing ignorance of sanitary dangers arising out of our national system of burial. But it is as surely to be expected that by-and-by the full advantage of the great hygienic reform offered by cremation will be universally understood, and it would be indeed a matter for sincere regret if gradual growth of popular opinion in this direction were to be arrested by such outbursts of fanatical opposition as would be excited by premature attempts at enforcing it. Deep-rooted ideas that are often the earliest implanted and the fastest fixed in the human mind, ideas round which are twined most cherished sentiments and most immovable prejudices, must never be ruthlessly attacked, but if success is to attend the efforts made to combat their influence they must be slowly and gradually proved to hinder the perfection of growth possible alike to societies and to individuals.

But with equal justice it may be claimed that those who hold ideas equally fixed regarding the irrational and undesirable nature of grave-yard interments, and who are anxious for the assurance that they may themselves be otherwise dealt with when dead, shall be allowed to exercise free will in this connection, and direct the cremation of their bodies without thereby bequeathing a legacy of difficulty to their executors. Such persons are animated by as sincere and as intense an abhorrence of slow decay with poison-spreading vapours arising from their bodies, as is experienced by the advocate for this unhealthy mode of interment; but the sentiment is not the same in both cases. With this difference, however, we have not to deal; but rather only with the question of abstract right involved, and which asserts that the freedom claimed and defended with such vigour on his own behalf by the observer of historic ceremonials should not be withheld from the cremationist, who asks only permission to exercise the right of selection in the matter of his own post-mortem destination.

THE HOSPITAL DEPARTMENT IN EGYPT.

It is as we expected. From the numerous articles on the subject that have lately appeared in the journals one thing, at least, is established—viz., that the devotion of the army medical officers in Egypt to the sick and wounded under their charge was beyond all praise. With regard, however, to those other branches of the military service upon which the medical department, as such, depended for its requirements, the fact seems to be established that, as a result of what is called the "system" under which all are supposed to work together, efficient co-operation was simply impracticable. Thus we learn that when the transports sailed from Alexandria for Ismailia the ship containing the whole of the material for the principal hospital at the new base was moved into harbour at Alexandria, and there detained until the material for one field and one base hospital had been landed, after which it sailed for Ismailia. In the meantime, the medical officers at Ismailia and Kassassin had

only the material of one field hospital to supply the wants of the sick and wounded—that is, the whole medical establishment was equal to the needs of two hundred patients, the admissions at the rate of sixty or seventy a day. In the hurry incidental to a change of base of military operations, the force became altogether separated from the hospital establishments necessary to meet its requirements. In the course of subsequent military operations, it is stated that the field hospitals were sent towards the front with insufficient means of transport, and with too few men as "orderlies" for their efficient working. Contrast this state of things with what is said of the Indian medical arrangements. With that portion of the force, transport appears, according to all accounts, to have been sufficient, and, at the same time, mobile. Hospital arrangements formed an integral portion of each force, instead of being loosely "attached" to it, as with us, and the results are on all sides allowed to have been perfectly satisfactory.

The inference to be drawn is plain enough. Let the "system" under which unsatisfactory results have taken place be swept away; let that which on the recent occasion, as on all other occasions when it has been allowed to have free scope and ample means, take its place. It is unfair to say that in the Crimean War the regimental hospital system failed in itself; that it "failed" on that occasion arose not from inherent defects in itself, but because official parsimony refused to give the means and appliances necessary for the working of the system. But what of the "general" hospital system on the same occasion? Let Scutari supply the answer. On the other hand, take the system of regimental hospitals in India. It is an acknowledged fact that, while in peace and in war, in times of great sickness, and during epidemics, regimental hospitals conducted by regimental medical officers have proved themselves by far the most successful establishments for their purpose that have hitherto been devised. Let both be re-established as they formerly existed, that is, as primary institutions; general hospitals, and "staff" medical officers being retained merely as supplementary establishments.

Notes on Current Topics.

Scarlet Fever in the Metropolis.

In consequence of the seriously rapid rate at which scarlet fever has been, and is spreading in London, leave has been sought and obtained from the Local Government Board, to re-open the small-pox hospital at Fulham, for the reception of cases. The Metropolitan Asylums Board have also re-appointed Mr. R. D. R. Sweeting to his former post as medical superintendent of the hospital, and it is to be hoped the vigorous measures thus instituted may be successful in coping with a threatening epidemic.

Although within the London district, however, cases of scarlet fever are so numerous, there is an unusual immunity from the disease enjoyed apparently in the suburbs. In the Forest Hill and Sydenham parishes, no single case of infectious disease of any kind, has, according to the medical officer, occurred for a week or more, and the

death-rate in the same area for the month was but slightly over 10 per 1,000; that of Brighton for the same period reached 21 per 1,000.

A Much Needed Improvement.

ONE of the greatest drawbacks experienced by ladies in London is the absence from our streets of any sort of convenience for them similar to those to be found in every principal thoroughfare for the use of gentlemen. As it is, with the exception of railway stations and a very few of the better class restaurants, no facilities are provided of the kind referred to for females, and any movement for supplying the deficiency should meet with widely extended support. Such a movement is now on foot, promoted by Miss Emily Wilcox, of 189 King's Cross Road, who will be glad to receive subscriptions in aid of the scheme. This lady proposes to open an experimental retiring room in the neighbourhood of King's Cross first, and as funds flow in, to increase the number by providing them at all crowded spots. The use of these places is to be open to all without charge, but a box will be provided in each for the reception of gratuities from whomsoever may be disposed to offer them, the expenses of outlay and maintenance to be defrayed from voluntary contributions. The scheme is one of the most deserving description, and ought not to have been left to private enterprise by the parochial authorities. We may, however, anticipate that when once provided, the expense of keeping the rooms in a fit state for use will be undertaken by the local governing bodies; and possibly as they appreciate the advantages conferred by the new conveniences they will themselves move in the direction of their further supply. On hygienic grounds alone the proposal deserves to command the fullest success.

The New Society.

ON Friday, October 6th, the newly constituted West London Medico-Chirurgical Society held its first meeting in the Board-room of the West London Hospital. The proceedings were opened by the President, Dr. Hart Vinen, with an introductory address, the chief object of which was to sketch out the objects and aims of the new association. This was followed by a paper contributed by Dr. Yeo "On the Antiseptic Treatment of Lung Disease," in the discussion of which several gentlemen, including Drs. Thudichum and Thorowgood, took part. The prospects of the young society are of the most encouraging kind, a very numerous attendance at the first meeting having proved the interest taken in its success.

"Personal Inquiry."

WE understand that "a special personal inquiry" is being conducted at Netley and elsewhere in reference to the general condition of sick and wounded soldiers on board of certain transports on the voyage home from Egypt. Nothing appears in the public prints to indicate the authority by and under which this "personal inquiry" is to take place, or what degree of responsibility, if any, is attached to the gentleman undertaking it. Speaking generally, all such "personal" investigations are to be deprecated. They place the responsible officers—namely,

those immediately and directly concerned—in an altogether false position; they open the door for underhand complaints and indirect allegations by unscrupulous individuals; they, moreover, introduce, as between patients and their medical attendants, a condition of what they must each look upon as *espionage*, detrimental to the interests of all concerned, and to the service generally. If grounds of complaint exist, by all means let them be fully investigated, and blame attached to those to whom it is fairly brought home. Let all such inquiries, however, be open and above board; let them be made by men whose status and authority in relation to them are defined and understood.

The Last Libel on the Profession.

IN a sensible and plain speaking article, our contemporary, the *American Medical News*, denounces in a recent number the calumnious attack made some time ago on the medical profession by Miss Cobbe. The charges that lady then saw fit to bring against doctors, have probably done more to inflict injury on her own character for fairness, than to affect the confidence with which the public regard the profession. It is perhaps a little unfortunate that the editor of the *Medical News* should have deemed the essay worthy of notice at all; but we should remember that this would not have happened had not the appearance of importance been given to it by its being answered in the magazine where it was printed, by such an authority as Dr. W. B. Carpenter. Miss Cobbe is undoubtedly an able writer and speaker, but has been conclusively shown by Prof. Owen and others, to be by no means a reliable informant, or at all times even as an honest critic of what meets her disapproval. It is no doubt a pity that she, or any one for that matter, should view the medical profession in a hostile light, but it would be unwise on that account for us to regard as in itself important, the senseless and unfounded railings of a not too scrupulous opponent. In future we trust our Transatlantic friends will not be misled into attaching very serious importance to what Miss Cobbe's prejudices may lead her to express.

Infant Feeding.

AT a recent meeting of the Paris Academy of Medicine, M. Tarnier read a paper on this subject. He began by stating that he much preferred cup or spoon feeding to a nipple-bottle when the child cannot be fed on mother's milk. Although condensed milk may be wholesome for adults, M. Tarnier declares that it is quite useless for young children; and he considers that nothing can be compared with the mother's milk, which is well known to be the first of all foods for infants. Artificial feeding has been tried in Paris with very disastrous results, as may be seen by the following statistics, drawn up by M. Bertillon:—In 1881, 60,856 children were born in Paris, of which 14,571 were sent away to be nursed, while 46,285 remained in the city. Of the latter number, 10,180 died, being a mortality of 22 per cent., while 5,202 (more than half) of the former died of *athrepsy*—that is to say, bad feeding. Of these 5,202 infants, 3,067 were fed with a nipple feeding-bottle. M. Tarnier then showed—1. That the lives of young children cannot be

safe unless they are fed on mother's milk. 2. If the mother's milk is insufficient, it should be *mixed* with the other. 3. Wet nursing, which is favourable for a child thus nourished, is equally dangerous for the child of that nurse. 4. Artificial nourishment is very much inferior to mother's milk, no matter how it is prepared, or what kind of milk is used. It is, therefore, better not to use it unless absolutely necessary. 5. To try and lessen the inherent dangers of artificial food, it is advisable that the subject be considered at the Academy itself. 6. It is also to be desired that an experimental farm should be established to supply the poorer families with cows' and asses' milk. 7. Comparative statistics would soon show the effect of the milk from such an establishment on the death-rate of young children. 8. A *crèche*, destined for the care of children who have been abandoned by their parents, should be attached to the farm. Such children should be brought up by artificial means, under the direction of persons appointed by the Academy. This *crèche* should be kept open until the Commission has finished its inquiries.

The Charge Against Guy's Hospital.

THE daily papers of the 10th inst. contained an account of an inquest held on a man who was reported to have been refused admission to Guy's Hospital shortly before his death, and charges of carelessness were made against the officers of the hospital. There seems to be absolutely no ground for the statements therein uttered, nor for the assertion of improper or insufficient treatment; and we cannot too freely express regret at the continued hostility exhibited towards Guy's by the public. At the present time the institution is ably and admirably managed, none of the abuses which were permitted for a time, being tolerated, and it should be thoroughly understood by every one that this is so.

On Transfusion of the Blood in Past Ages.

In the "Memoirs of Bouteiller of Ardenay," published in the year 1670, it is stated that one Denys, a Professor in the University of Rheims, who believed in transfusion of the blood, tried, while he was working at mathematics in Paris, its effects on a madman, who, when in his worst frame of mind, ran about the streets naked, and tried to burn everything he came near. The result was very beneficial. He soon became quite sensible, and remained so for two months; but, again falling into the same condition, Denys repeated the operation of transfusing into him the blood of a calf, which was the animal he chose for this purpose, but the weak state of the patient prevented his giving him the entire quantity required for recovery. After having passed some days in a sane condition, the man again became mad, and his wife, in despair at seeing him again in this state, had recourse to Denys, and begged him to renew the experiment on her husband. The doctor, knowing the extreme weakness of his patient, was very much against making a third trial; nevertheless, at the earnest solicitation of the man's wife, he performed the operation. The unfortunate patient, however, suffered excruciating pain, in proportion as the animal's blood ran into his veins, so much so that he uttered frightful cries, and Denys

stopped the further transfusion. He was put to bed, and died in six hours afterwards. The widow followed Denys to Chastelet, and obtained a decree of personal liability against him, and demanded damages. Denys, in his turn, obtained a decree against her, stating she had poisoned her husband; but the decision was in favour of the widow. The case was carried to a higher court, where M. Bouillé, father of the first President, defended Denys, and M. Pageot spoke for M. Emeray, a Parisian surgeon, who had assisted Denys in three of the transfusions which he made, while M. Robert pleaded the cause of the widow. Denys spoke in Latin, and the case, having been well argued on both sides, after the summing up of the facts by the Attorney-General (Bignon), was dismissed. It was then forbidden to practise transfusion of blood, for which the penalty was decreed to be corporeal punishment. This order was given by the first President (M. De La Moignon) on Thursday, 2nd January, A.D. 1670.

On the Use of Carbonate of Ammonia Sachets for Bronchitis.

M. MEISENS having observed the good effects of the atmosphere of a stable on those suffering from pulmonary diseases, which are rightly attributed to the emanations of carbonate of ammonia, he thought that continued, yet moderate, respiration of this salt might be useful in other affections of the respiratory organs. After a serious attack of bronchitis, he decided on trying on himself the effects of carrying a little bag round his neck containing little pieces of carbonate of ammonia. From the first day the amelioration was felt, and the cough soon disappeared entirely, while often persons who suffered from chronic bronchitis also obtained relief. The use of little bags of carbonate of ammonia are intended to produce the same result as the air of a stable or a gasworks.

The "Young Soldier" Hoax.

AFTER all that has been said and written on the subject of *infantry* as soldiers in Egypt, it now transpires that, like *snakes in Ireland*, there were none, for the very sufficient reason all such had been eliminated from the ranks of regiments about to be sent there prior to embarkation. From inquiries made on the spot the following particulars are gleaned, namely:—The 87th Regiment left so many of its young soldiers at home that the battalion was only half its proper strength in Egypt. The men of the 74th Highland Light Infantry average about eight years' service. The Cameron Highlanders have four hundred and sixty men upwards of twenty-four years old, and two hundred and nineteen between twenty-one and twenty-four, none under twenty. Of the whole, two hundred and thirty belong to the Reserve. Of the Gordon Highlanders three hundred and seventy are over twenty-four years of age, and none under twenty-one. One hundred and fifty-four belong to the Reserve. Thus it is evident that these regiments cannot be considered as young. They have a strong nucleus of steady old soldiers in the ranks, and differ very widely from regiments composed of short-service men. The Black Watch, which is the youngest in the Brigade, has, nevertheless, three hundred men of over six

years' service. All under twenty were left behind, and their places filled up with Reserve men. During the action at Kassassin the brunt of the fighting fell upon the 60th Rifles and the Marines, both old regiments. Thus the campaign is very far from proving the merits of boy regiments. It will be interesting to see the proportion of sick among the young and the formed soldiers.

Free Trade in Irish Professorships.

WHEN the King's Professorships of Medicine and Midwifery in the Dublin School of Physic recently became vacant, we took occasion to enter our protest against the continuance of a rule long since adopted by the College of Physicians and the Board of Trinity College (who jointly govern the School of Physic), to the effect that no future King's Professor should be allowed to hold an appointment as medical officer of any clinical hospital other than Sir Patrick Dun's. This rule had been made to order, when Sir Patrick Dun's Hospital languished as a purely medical hospital, and its intention obviously was to give that institution a monopoly of the medical Professorships attached to the University of Dublin. We have perhaps no right to say that the effect of that monopoly has been to starve the School of Physic of the best teachers, but we do not hesitate to assert that, if the School secured good men for its Professorships, it was because the value of the Professorships induced good men to accept the offices, notwithstanding the drawback that they would have to enter the cold shade of an hospital which had little clinical material and few students. The School of Physic should not be handicapped for the advantage of any hospital, nor should the best teachers be prohibited from seeking Professorships therein by the necessity for resigning their own hospitals, and as we desired to aid in breaking down the monopoly of which we have spoken, we advocated the immediate repeal of the rule. We learn, therefore, with much satisfaction, that the Fellows of the Irish College of Physicians, having been advised by the most eminent counsel that any such restriction upon candidates for the Professorships is altogether illegal, have repealed it as far as they have power. This repeal needs to be confirmed by the Board of Trinity College, and at present it will not be so confirmed, so that it will be inoperative. But the decision of the College will have immense moral effect, and as it will certainly be approved of by the good sense of the profession at large, and of the University Senate, we are in hopes that at the next election to a King's Professorship the candidates will be admitted to compete on "a fair stage and no favour."

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 26, Bombay 23, Madras 36; Paris 23; Geneva 14; Brussels 21; Amsterdam 22; Rotterdam 16; The Hague 20; Copenhagen 24; Stockholm 16; Christiania 14; St. Petersburg 39; Berlin 26; Hamburg 18; Dresden 23, Breslau 30, Munich 21, Vienna 20, Prague 24, Budapesth 24, Trieste 26, Rome 21, Turin 16, Venice 16, New York 29, Brooklyn 20, Philadelphia 18, and Baltimore 26.

The Annual Elections at the Irish College of Physicians.

ST. LUKE'S day, being the statutory day for electing the officers and Fellows of the King and Queen's College of Physicians, falls this year on to-day (Wednesday), the 18th. Dr. George Johnston, who was induced to accept a second year's Presidency on the death of Dr. Hayden, who was designated for the post of honour at the head of the College retires, and is to be succeeded *nem. dis.* by Dr. William Moore, lately King's Professor of Physic in the School of Physic, Dublin. Dr. Finny also resigns the Registrarship of the College, which he filled with so much satisfaction to the Fellows, on being appointed to that Professorship. He retires after nearly twelve years' service, and will probably be succeeded by Dr. John William Moore, Physician to the Meath Hospital. There will be by-contests for the censorships and examinerships, respecting which we will inform our readers next week.

Methylated Medicines for Paupers.

AT Hull recently, a chemist and druggist was fined £10, for unlawfully selling paregoric in the preparation of which methylated spirit had been used. Two samples were found to contain methylated spirit instead of ordinary alcohol, but in different quantities in each, which must have been taken from two different sources. Now that the Irish Local Government Board has law and precedent in its favour, we would suggest that it might, with benefit to the poor of Ireland, recover fines of £10 a piece from the Irish union drug contractors, who, for years have been supplying methylated tinctures instead of those contracted for and paid for. It is notorious that certain of these contractors have been in the habit of supplying the guardians with tinctures at a less price than the spirit they *are supposed* to be made of can be bought in the open market, from which arises the inevitable conclusion that these traders must be either the most philanthropic of men or unconscionable rogues.

The Traffic in Diseased Meat in Dublin.

FROM time to time we have had occasion to animadvert in emphatic terms upon the traffic in pleuro-pneumonic cows carried on by certain Poor-Law Unions in Ireland under the cognisance and permission of the Irish Local Government Board. This disgusting method of saving the rates proved profitable up to the time when an official engaged in supervising the diseased meat traffic on behalf of one of the Dublin unions became a defaulter for a large amount, and on inquiry it came out that the selling of fever-laden meat to unscrupulous butchers had been carried on, practically, without hindrance. The Irish Local Government Board was at length obliged to hold an investigation, with the result which we have stated, and we venture to hope that the light which that inquiry has shed upon the matter will cause the Local Government Board to set its face against this method of saving the taxes. The medical advisers of the Irish Local Government Board must know that it is perfectly untrue and unscientific to assert that the flesh of animals stricken with an infectious and usually fatal fever, can, in any stage of the disease, be fit for human food, and no one can say how much of the diarrhoea and cognate affections from which

the Dublin poor suffer may be due to their consumption of diseased meat put on the market by the Poor-law guardians. Beside such a traffic the chopping up of cats for sausages is an innocent method of economising the available food supply.

Insalubrity of the West Coast of Africa.

To the last number of the *Journal of Science* Mr. S. Billings communicates a letter, which contains statements and experiences of special interest to Army Medical Officers who are offered service in this much-abused locality. Mr. Billings quotes a statement that

"On the West coast of Africa testotallers die first, hard-drinking men second, whilst the temperate live longest. I have had some considerable experience of living on the West Coast of Africa. Take the 'temperate' in the largest sense the remark is true. A man may be temperate in the use of alcoholic drink, but intemperate in eating, which I think is more fatal than the use of liquors and wine: these latter in a great degree counteract the effect of the miasmatic exhalations. My observations showed that excessive eating was more fatal than excessive drinking. As a rule the climate was most fatal to new comers who were Germans. Their mode of dress was such that persons so clothed were always hot and uncomfortable, a clammy moisture continually clinging to the skin, owing to the arrest of the exhalations by the outer coat. There came under my observations three persons who did not perspire; they all died within two months of their arrival. There is also a curious physiological fact which I observed, but have never seen it remarked on, viz., that the skin of the negroes when in health—even when streams of perspiration were pouring down them—was to the touch as cold as marble; heat on the skin was to them always an indication of fever. As a rule, excess in drinking is not exhibited, new comers being warned against it. Brandy-and-water drinkers fared worse than wine drinkers. Beer, in my opinion, is almost poison. The bad name given to the West Coast of Africa arises more from the excesses of its exotic denizens than from the real effects of the climate. After the acclimative fever—which all have more or less severely—the health of the old denizens is good; a little fever sometimes, and that is all. I do not think that a more pleasant (and I may say, healthy) climate can be found than the West Coast (Gambia I am speaking of) of Africa from the end of October to the commencement of June. From June to October is bad enough. August is generally the most fatal month to new arrivals."

Treatment of Necrosis by Sand Baths.

In the *Deutsche Med. Zeitung*, No. 40, is a note on the above method of treatment, as practised by Dr. Ewsejenko in a country district in Russia, in which facilities are wanting for the treatment of these cases by the usual methods. It has the great advantage of not being disagreeable to the patient.

The Russian peasant sleeps on the stove. A sufficient quantity of sand is spread out on the top of this, and daily heated to a rather high temperature, and here the patients live for weeks in the hot sand. More accurate details are wanting, but the notice gives nine cases as having been thus successfully treated.

We learn that Dr. T. P. Anderson Stuart has been elected to the Professorship of Anatomy and Physiology in the University of Sydney.

ONE of our weekly contemporaries announces that Madame Ratazzi, who is said to be about fifty years of age, is about to present her third husband with a son and heir.

The Lisburn Infirmary.

WE understand that disputes have arisen with reference to the appointment of a successor to Dr. Thompson, the Surgeon of the Co. Antrim Infirmary, who unhappily was killed by a train at the Dunmurry Station. Shortly after this melancholy event, Dr. George Lombe St. George was appointed by the Board of Governors to succeed Dr. Thompson, but we hear that the legal notice of the election was not given, and that the election is therefore contested. By the 5th and 6th Geo. III., cap. 2, section 4, it is essential that 21 days' notice shall be sent to the Governors, and it is said that this was not done.

Cæsarean Section.

A SUCCESSFUL case of Cæsarean section is reported in the *Archiv für Gynæcologie*, xix. 3, by Dr. Leopold of Leipzig. The patient was a woman 29 years of age who had already borne one child, extracted by cephalotripsy after perforation. She was 125 ctm. in height, and had a universally contracted rachitic pelvis of a flattened a-ce-of-hearts form. The conjugate diameter was 6 ctm. The operation was performed under antiseptic precautions. Previous to opening the uterus, the serous membrane was dissected off a longitudinal elliptical space, and turned back, after which a melon-like slice of uterus was removed. This procedure was with the object of getting sufficient serous membrane to allow of its edges being turned down previous to the application of the sutures. At the end of the third week both mother and child were convalescent.

A Doctor on Medical Men.

DR. THOMPSON, of Omagh, has recently circulated the address delivered by him in his capacity of President of the Belfast Branch of the British Medical Association, and a marked copy of it has been sent us, from which we learn that Dr. Thompson is disposed to be critical of Irish medical affairs. He thinks medical men are not in esteem; that they are in the habit of abusing each other; that consultants are not what they ought to be; that, generally speaking, doctors are badly educated; and our system of education altogether worthless. He says "the person who frequently succeeds best in the world is the bustling busybody who, with a soft and unctuous manner, and an imposing equipage, parades his learning—or rather his ignorance—to a sympathetic, indiscriminating public." All this is not flattering to the *amour propre* of the profession, but, if true, it may possibly serve some not obvious purpose to state it publicly. But Dr. Thompson should have closed his gall-bottle before he insulted the leaders of his own profession in Ireland by asking, as he does, "Where in Ireland have we an authority of importance in any of the various departments of medicine or surgery, and where are we to look for the successors of Stokes, Corrigan, Colles, Adams, Crampton, Carmichael, and Robert Smith?"

No doubt echo would answer, Omagh! But outside that centre of learning, we would venture to assure Dr. Thompson, in the words of the proverb, that there are as good fish in the sea as ever were taken out of it. In the profession in Ireland at this moment there are as good surgeons and physicians as ever—men who, when

they are dead, will be canonised, as are those whom Dr. Thompson names. While we have Banks, Little, Porter, Butcher, Colles, MacDonnell, Gordon, Kidd, Atthill, and such like, we are in a good position to answer Dr. Thompson's invidious comparison; and we venture to observe that we fail to see either good taste or wisdom in his philippic against his own profession.

Recognition of Irish Workhouse Hospitals by the Royal Irish University.

DR. LAFFAN, medical officer of the Cashel Workhouse, answers, by a letter addressed to the *Freeman's Journal*, the observations which we made last week on this subject. As he does not make any attempt to meet any one of the objections we raised to the proposal to recognise workhouse hospitals as clinical teaching institutions, but confines his criticism to the narrow limits of attributing motives to the editor of this journal, and quoting the experiences of a student friend who could learn nothing in a Dublin hospital, we do not see any necessity for a replication to his observations. We, however, take the opportunity to ask Dr. Laffan a couple of questions which he has in vain been asked before. Does he propose that *all* Irish union hospitals shall be regarded as clinical teaching institutions? If so, how does he propose that the *bond fides* of the instruction and of the certificates issued by these hospitals shall be guaranteed, inasmuch as it is obviously impossible for any central authority to inspect or supervise the teaching of 163 provincial institutions? If he would propose that only a few of these hospitals be permitted to issue certificates, how is the selection to be made, and whose certificates would he refuse to accept?

Infanticide.

AN inquest was held last week by Dr. Lionel Weatheley, at Mark, in Somerset, on the body of a female child which, after living some minutes, had died by suffocation. The mother denied that she was pregnant up to the moment of labour, and delivered herself secretly, the body of the infant being subsequently found in her bedroom. The jury committed her for trial on a charge of manslaughter, and the coroner made some strong but justifiable remarks on the carelessness of the prisoner's employers in abstaining from calling in medical assistance to prove the justness of their suspicions with the girl's condition. It should, however, be remembered that this course of action is a very dangerous one for the medical attendant, and in the present state of the law liable to lead to vexatious prosecution. The whole question is a difficult one to handle.

Medical Advertising in Dublin.

A CLERICAL gentleman comes forward to illustrate in the Dublin papers of last week the ignorance and inconsiderateness of editors and the general public respecting what is and what is not consistent with professional decency. This gentleman makes an appeal for the Dublin Orthopædic Hospital, and enforces his demand for money by a reference to the extraordinary skill of the surgeon of the institution, describing with many adjectives the case

of a patient treated therein, and naming the surgeon in full, lest the public should be in doubt as to his individuality. We are assured that the surgeon referred to had no knowledge or participation in the puff, and we believe the statement; but we are reminded that this is not the first time, nor the second time, that we have been obliged to take exception to the disreputable method of begging pursued by this hospital, and to remonstrate against its officials using the name of its medical officers for the purpose of their mendicancy. We assume that it is easily within the power of any surgeon to stop a proceeding so inconsistent with professional decency, and we hope that he will so express himself to the reverend advertiser and the other officers of the hospital as to make such another puff impossible. If those who solicit aid for the institution cannot manage to do so without dragging in the name of its surgeon, as has been done in this instance, we shall be obliged on the next occasion to appeal more directly to professional feeling against the proceeding.

AN admirable portrait of the late Dr. Hudson, executed by Sir Thomas Alfred Jones, President of the Royal Hibernian Academy of Painters, has been recently presented to the King and Queen's College of Physicians in Ireland by Dr. James Little, Professor of Practice of Medicine in the Irish College of Surgeons. The portrait occupies a worthy niche side by side with the pictures of Beatty, Mayne, Corrigan, Churchill, Sir P. Dun's, and other equally celebrated Fellows of the College.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 7th inst., was 78, and the death-rate 18 per 1,000. Under 1 year there were 23 deaths, and above 60 there were 17 deaths, of which 1 was above 80. Diseases of the chest accounted for 21 deaths, and zymotic causes for 6, of which 4 were scarlet fever and 2 diphtheria. The intimations numbered 120, including 15 fever, 99 scarlet fever, 3 diphtheria, and 3 measles.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 7th inst., were at the rate of 24 per 1,000 per annum, against 24 in the preceding week, and 22, 23, and 30 in the corresponding periods of 1881, 1880, and 1879.

ANOTHER CASE OF HYDROPHOBIA.—Within the past few years cases of hydrophobia have occurred with alarming frequency. On the 5th inst. a death occurred from this frightful disease at the Royal Infirmary, Glasgow. It appears that about the 14th of March last the deceased was bitten by a mad dog, which was running about the streets at the time. The dog, after having bitten him, pursued its way towards Gallowflat, Rutherglen, where it bit a footman, and also made an attack on Mr. Reid, who, however, succeeded in warding it off. The infuriated animal was pursued back to Rutherglen, where it was afterwards destroyed by the police. Nothing unusual appeared wrong with the man bitten till about four days before death.

INCREASE OF SCARLET FEVER IN GLASGOW.—In his fortnightly report to the Glasgow Town Council on the 9th inst., Dr. Russell mentions that scarlet fever has been making rapid

progress in the city, and that the deaths from this cause have increased from 9 to 20, and are distributed over all parts of the city. The officer of health also points out the danger of carrying children suffering from whooping-cough in tramway cars, and states that the ventilation of the older types of tramway cars in this city is utterly inefficient. Recommendations on the subject by the Health Committee were forwarded to the Tramway Company.

EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.—Dr. J. Halliday Croom, whose quarter of duty expires on 1st November, will then be succeeded by Professor Simpson for the ensuing three months. The present house-surgeons, Charles Harper Browne, B.A., and Herbert Rendell, will be succeeded at the same time by George Keppie Paterson, M.B. C.M., and Alfred P. Hillier, B.A. M.B. C.M.

COLONIAL EDUCATIONAL APPOINTMENT.—Dr. T. P. Anderson Stuart, M.D., C.M., Assistant to the Professor of the Institutes of Medicine in the University of Edinburgh, has been appointed by the Senate of the University of Sydney to fill the new Chair of Anatomy and Physiology in that University. Dr. Stuart was a most distinguished student at the University, and at his graduation was awarded the Ettles Scholarship and a gold medal for his thesis on the Physiological Action of Nickel and Cobalt.

UNIVERSITY OF ABERDEEN.—MEDICAL BURSARIES.—A meeting of the General Council of the University of Aberdeen was held on the 11th inst., to receive a motion by Professor Struthers to the following effect:—"That the Council respectfully represent to the University Court the importance of making known the want of medical bursaries in the University, as the number of bursaries for students of medicine is still very small compared with the number of students in that Faculty." Professor Struthers said one of the two great wants of Aberdeen University had recently been supplied by the endowment by Sir Erasmus Wilson of a Chair of Pathology. The want of bursaries in the Medical Faculty was still clamant. In the Faculty of Arts, Dr. Struthers pointed out, there were in the session 1880-81, 382 students, holding amongst them 282 bursaries, of the aggregate annual value of £5,068 1s.; in the Divinity Faculty there were 32 students, and 32 bursaries of the annual value of £732 10s.; and in the Medical Faculty 335 students, possessing only 17 bursaries, of the value of £345 5s. In addition, there were in the Arts Faculty scholarships and prizes amounting annually in value to £735; in Divinity, scholarships and prizes amounting to £51. In Medicine there was one scholarship of the value of £35 and three gold medals. The proportion of students to bursaries he showed by an analysis of the above figures to be—in the Arts Faculty, three to two; in the Divinity Faculty the number of students was just equal to the number of bursaries; while in the Medical School the proportion dwindled down to one bursary for every twenty students. Dr. Struthers pointed out that the fewness of the bursaries in the Medical compared with the Arts Faculty was due to the fact that formerly medical education was obtained, not by University teaching, but by apprenticeship of the student to a regular practitioner. He urged the greater necessity for the foundation of bursaries in the Medical than in the Arts Faculty by showing the comparatively greater expense connected with medical than with classical education, and expressed the hope that for the average 300 students who studied medicine annually at Aberdeen University there would be provided not less than 100 bursaries of the value of from £20 to £40 each. He especially invited the attention of those having money to leave for ~~gratuitous~~ public objects to the pressing necessities of the University in this respect. Principal Brown seconded the

motion, and suggested that the address delivered by Dr. Struthers be printed, and circulated in this country, the colonies, and in the East Indies, with a view to inducing wealthy persons to endow the necessary number of bursaries. The motion was unanimously agreed to.

HEALTH LECTURES IN GLASGOW.—The Young Men's Christian Association of Glasgow have arranged for another course of "Health Lectures" this winter, and we notice that the names of several pushing medical men are extensively advertised in this connection. The taste and expediency herein involved are, to say the least of them, of a questionable nature; and we are somewhat surprised to find the name of a respected and modest practitioner figure as a lecturer on "Healthy Motherhood." The corresponding lecture last winter was on "Healthy Womanhood," and its extensive distribution among all classes of the community was regarded with merited disfavour. After a "Young Men's Christian" Restaurant, and a "Young Men's Christian" Public Medical Lectures, we are tempted to ask, what next? The *Herald* tells us that "the names of the lecturers are a guarantee for the ability with which they will be handled." We shall see!

AYR NEW HOSPITAL.—Dr. Charles Scott, Dundee, has been appointed House-Surgeon to Ayr New Hospital, and Surgeon to the Dispensary.

COMBE LECTURES.—What with "Health Lectures," "Combe Lectures," and preaching doctors, the community in Scotland ought surely to be kept physically and spiritually straight. In the Combe Lectures great interest seems to be taken by the public, and the courses arranged for the ensuing session include the delivery of lectures by the lecturer, Dr. Andrew Wilson, at Perth, Falkirk, and Leith, and also, by special arrangement with the local societies, at Hawick and Galashiels. The lectures at Perth and Leith are to be delivered during the autumn and winter, those at the former city beginning on October 17th, and at Leith on October 30th, each course of eight lectures being continued weekly to the close. At Falkirk the lectures will be given early in 1883. The courses at Hawick and Galashiels are intended to supplement the Combe lectures given there last session.

FEVER HOSPITAL ACCOMMODATION IN EDINBURGH.—At a special meeting, held last Friday, of the Law and Public Health Joint Sub-Committee of the Lord Provost's Committee on Fever Hospital Accommodation, we understand it was recommitted to a special committee, consisting of Bailies Cranston and Anderson, and Councillors M'Lachlan, Baxter, Clark, and Russell, to consider the whole question of fever hospital accommodation in Edinburgh, to confer with the managers of the Royal Infirmary, and to bring up a written report containing a definite proposal to be submitted to the Town Council for consideration.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At the first meeting of the session of the Glasgow Medico-Chirurgical Society, held in the Faculty Hall, on the 6th inst., the following gentlemen were elected office-bearers for the session 1882-83:—President, Dr. W. T. Gairdner; Vice-Presidents, Dr. Robert Grieve and Dr. Alexander Robertson; Council, Dr. George Mather, Dr. H. C. Cameron, Dr. Robert Forrest, Dr. Lapraik, Dr. D. Maclean, Dr. J. C. Woodburn, Dr. Wm. Whitelaw (Kirkintilloch), Dr. W. A. Wilson (Greenock); Secretaries, Drs. W. L. Reid and J. W. Anderson; Treasurer, Dr. Hugh Thomson.

TYPHOID FEVER, although still prevalent in Bangor, shows signs of abatement, the cases during the past few days being fewer and of a less severe type.

Literary Notes and Gossip.

AMONGST the new works in Medicine and allied sciences issued during the past few days are—Vol. I. of Reeves's new work on "Human Morphology," a new edition of Bristowe's "Theory and Practice of Medicine," Vol. II. of Wood's "International Surgery," Vol. II. of Fleming's "Contagious Diseases of Animals," Hill's "Bovine Pathology," Dolan's "Whooping-Cough" (Fothergillian Prize), &c. Dr. Quain's "Dictionary of Medicine" is expected in a few days, and a new edition of Dr. Graily Hewitt's "Diseases of Women" will be ready in November.

DR. MAYNE publishes, through Messrs. Churchill, a table, entitled "Notes on Poisons," which is practically a reproduction from the second edition of his "Therapeutical Remembrancer." We cannot speak in terms of praise of this synopsis, the principal advantage of which lies in the form it is presented under. To those already fully acquainted with the tests, antidotes, and symptoms associated with the various poisons the chart may be of service, but even such persons must be perplexed, both by the arrangement and nature of its contents.

THE student of elementary anatomy and practical physiology will find much valuable information in a little book now before us entitled "The Tissues and their Structure," by Alexander S. Kenny, M.R.C.S. (David Bogue, London), the value of which is greatly increased by the addition of some carefully-executed illustrations of the various tissues of the body. We have gone through the pages of the book, and find the information accurate and carefully prepared for the wants of the student, and even those who have passed the stage of pupillage will find much to instruct and interest them.

THE subject for the annual competition for the "Howard Medal" (1883) is—"The best Exposition of the Experiences and Opinions of John Howard on the Preservation and Improvement of the Health of the Inmates of Schools, Prisons, Workhouses, Hospitals, and other Public Institutions, as far as the Health is affected by Structural Arrangements relating to supplies of Air and Water, Drainage, &c." Candidates are referred to the text and foot-notes of Howard's two works on "Prisons" and "Lazarettos." Besides the medal, the Council of the Statistical Society of London have decided to grant the sum of £20 to the successful essayist.

As the "Medical Man's Handy-book," by William Shepperson (J. and A. Churchill, London), owes its origin to "the desire of several medical men," it must doubtless have been wanted, though we may fail to see its individual merits. The information it contains is correct so far as it goes, inasmuch as it is copied almost *verbatim* from several well-known sources; but there is nothing in it which should not be already known to the most ordinary practitioner, who, if he need such a handy-book as Mr. Shepperson has considerably prepared, should at once renounce the medical profession for something nearer his level, and of less danger to the general public.

THE staff of the London Hospital have issued a new *Pharmacopœia*, which is considerably larger than its predecessor, not merely because it includes recent additions to our materia medica, but because it also aims to be a useful guide to the students of the hospital in the art of prescribing. An appendix for the special use of the students gives instructions for case-taking, for the estimation of urea by sodium hypobromite, for the use of Fehling's solution, a list of poisons and their antidotes, a list of abbreviations used in prescriptions, tables of metric weights and their equivalents, and a table of doses. The book is of convenient size for the student's pocket, and well got up.

WE understand that Professor Politzer's long-promised work on "Diseases of the Ear and Adjacent Organs" will be ready this week, and that the authorised English translation, by Dr. Patterson Cassells, of Glasgow, will appear almost simultaneously in England and America with the completed work in Germany. If we remember rightly, Politzer commenced this treatise, which is in the nature of an exhaustive

text-book, about three years since, the first volume in German being issued last year. He has now completed vol. ii., and, with it, the work; but in the English edition the whole will be issued as a single volume, of about 800 pages, the redundancy of the German language giving place to briefer Saxon.

AN aged contributor to this journal—Dr. W. St. George Davies—passed away at Brighton a few days since, having attained the distinction of being the oldest member of the profession in the present decade. Nearly 80 years ago he was attached to the Royal Navy, and was engaged as surgeon on board ship in nearly all the historical battles of that period. The last of his day, his place too is vacant, he having reached the patriarchal age of 96. Dr. Davies had retired from the Navy many years, and was in the enjoyment of a full service pension. His last literary contribution was to the columns of this journal, entitled "Naval Medical Reform."

THE day is probably not far distant when every leading publishing firm will issue a magazine of its own, with the name of the house as its distinctive title. Thus, we already have *Macmillan's Magazine*, *Cassell's Magazine*, *Chambers' Journal*, and next month we are promised the first number of *Longman's Magazine*. None of these serials, however, partake of the nature of medical publications, although the houses they represent are publishers of a number of medical works. The strictly medical firms have already their own journals, but the time has not arrived when the word "medical" can be safely dropped from their several titles in favour of the name of the head of the house.

THE completed Report of the Examinations of the Medical and Surgical Corporations of the United Kingdom, by the Visitors appointed by the General Medical Council, is now to hand. We have from time to time commented upon isolated reports, and now that the whole is public, and is, moreover, purchasable for a small fee, we advise those interested in the questions of reform in medical education and examination to obtain the volume for themselves. There is a carefully prepared index, and each page is annotated in the margin by Mr. Miller, the General Registrar. The "Statement" by Mr. Pridgin Teale, which is inserted as a sort of preface to the work, will be read with considerable interest, as a thoughtful and honest exposition of facts, with suggestions.

THE case of Mr. Aitken, who died recently at Columbo, Ceylon, from—it was said—an overdose of male fern, given while under treatment of Dr. Coghill, of that place, has been the theme of considerable gossip in home circles lately. The question turned upon the authority of a standard work on therapeutics, from which the accused averred he took the prescription. The dose was undoubtedly a dangerous one, and the quantity specified probably a misprint; but we are not of opinion that it was the cause of death; on the contrary, that it was due to exhaustion from diarrhoea. In any case, the production at the initial stage of the inquiry of the prescription in the book in question was deemed sufficient for the acquittal of Dr. Coghill, and the inquiry was not proceeded with.

AMERICAN publishers are notably enterprising—we are not now referring to their practice of reproducing European authors without permission, but in the production of what may be termed "big" books of medicine, of which "Ziemssen's Cyclopædia" is a type. Last year Messrs. Wood and Co., of New York, announced an "International Encyclopædia of Surgery" in six volumes, by various authors, each volume to appear quarterly. So far they have been unable to carry out their design, as a year has elapsed between the publication of vols. i. and ii. If scientific surgery continues to make the strides during the next six years it accomplished in the past, and the remaining volumes of this work only appear at yearly intervals, the first will be considered obsolete in many particulars by the time the last appears. We counsel Messrs. Wood to hurry on the work if they desire to give it a chance of success.

THE catalogue of the ill-fated Berlin Exhibition for Hygiene and Life-saving Appliances lies before us. It will be remembered that from this period of last year and onward the exhi-

bition was one of the chief objects of interest of Germany and Germans, an interest that increased day by day until that on which the whole vast fabric with its precious, even invaluable, contents became the prey of the devouring element. To read now the exact and laboured precautions that had been taken and were to be taken to prevent the possibility of a conflagration is a striking commentary on that fate to the influence of which we are told both men and mice are subject. Everything seems to have been done (on paper); no precaution seems to have been omitted, and yet the fire broke out, and in spite of all the elaborate precautions, consumed everything. The catalogue is well got up, and does credit to the firm of publishers in charge of it (Th. Fischer Dorotheen, Strasse 8, and Julius Springer Monbijou, Platz 3). A perusal of it even now will at least show the direction or scope of the late Exhibition, and as this is to be reproduced during the coming year in all its completeness for those interested in these subjects (and who is not?), the cost of the volume and labour of perusing it will not be thrown away.

* *

NEW BOOKS AND NEW EDITIONS.—The following have been received since the publication of our last list:—The International Cyclopedia of Surgery, Vol. II. Theory and Practice of Medicine (4th edition), by J. Syer Bristowe, M.D., F.R.S. Regional Surgery, Part I., Head and Neck, by F. A. Southam, F.R.C.S. The Teeth, by S. H. Linn, M.D. First Aid to the Injured, by Dr. Esmarch (translation). Diet for the Sick, by J. J. Ridge, M.D. (2nd edition). Diseases of the Uterus, by A. Courty (translation). The Surgical Treatment of Hemorrhoids, by W. Whitehead, F.R.C.S. Notes on Poisons, by J. Mayne, M.D. Synopsis of Chemistry, by T. W. Drinkwater, F.C.S. Therapeutical Remembrancer, by J. Mayne, M.D. (2nd edition). Vaccination and Small-pox, by W. A. Hardaway, M.D. The Contagiousness of Pulmonary Consumption, by J. Burney Yeo, M.D. Some Practical Observations on Vaccination, by W. H. W. Wilkinson, L.R.C.P. Treatise on Electro-Diagnosis in Diseases of the Nervous System, by A. Hughes Bennett, M.D. St. Thomas's Hospital Reports, New Series, Vol. XI. New Commercial Plants and Drugs, by Thos. Christy, F.L.S. Lock Hospitals and Lock Wards in General Hospitals, by F. W. Lowndes, M.R.C.S. Hereditary Eruptions of the Skin in Early Life, by J. Startin, M.R.C.S. On Animal Vaccination, by C. R. Drysdale, M.D. On Cattle-plague Vaccination, by Dr. C. Pigeon. The Climate and Fevers of India, by Sir Joseph Fayrer, M.D., F.R.S. A Critique on the Criticisms of the Simplicity of Life, by Ralfe Richardson, M.D. Human Morphology, Vol. I.: The Limbs and Perineum, by H. A. Reeves, F.R.C.S. Ed.

Correspondence.

SULPHUROUS ACID IN CONSUMPTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having received several letters from members of the profession asking for the exact composition of the compound sulphurous acid vapours which I described in my paper on "The Treatment of Consumption with Sulphurous Acid," published in your issue of Sept. 27th, and being unable to reply to each, I will now, with your permission, give the formulæ of these vapours, and hope that all will consider this a satisfactory answer to their communications. They are—

No. 1.

Vapor. acid. sulphurosi c. ol. pini sylv.

R. Ol. pini sylvestris, ℥ 80;

Kaolin, gr. 20;

Acid. sulphurosi, B.P., ad ʒj.

Mft. inhalatio. Five to ten drops to be inhaled three times a day.

No. 2.

Vapor. acid. sulphurosi c. ol. eucalyptil.

R. Ol. eucalyptil, ℥ 80;

Kaolin, gr. 20;

Acid. sulphurosi, B.P., ad ʒj.

Mft. inhalatio.

No. 3.

Vapor. acid. sulphurosi c. benzoin.

R. Acid. sulphurosi, ʒss.;

Tinct. benzoin. comp., ʒss.

Mft. inhalatio.

In these inhalations the essential or specific ingredient is the sulphurous vapour, the oils, though possessing intrinsic virtues, being here mainly used to disguise the odour and lessen the irritation of the sulphur. The kaolin helps to mix the oils, but is not necessary, for a little spirit of wine might answer the purpose.

In commencing these vapours, the benzoin combination should have a first trial, and it is well to use a wire or perforated flexible zinc inhaler, carrying a bit of sponge on which the fluid can be dropped. This obviates the fatigue attending the use of hot-water inhalations. The sponge should not be allowed to touch the lips.

Your obedient servant,

D. H. CULLIMORE, M.D.

54 Welbeck Street, London, W.,

Medico-Legal Intelligence.

THE PAYMENT OF FEES FOR MEDICAL CERTIFICATES.

DURING the hearing of a charge of attempted murder at the Portsmouth Police Court on Saturday, a point of some interest to the profession arose. It transpired in the course of the evidence that the house-surgeon at the Royal Portsmouth, Portsea, and Gosport Hospital (Mr. Williams) had refused the police a certificate of the condition of the injured woman—who had been detained in the institution in consequence of the severity of the injuries received—unless he was paid for it. The magistrates expressed their surprise that such a course should have been pursued, but as the surgeon was not then in attendance they agreed not to commit themselves to any condemnatory expression of opinion regarding the matter. Subsequently, when the surgeon came into Court, the Chairman of the Bench asked if it was true that he had refused a certificate to the police because he was not paid for it? The Surgeon. Certainly. The magistrates' Clerk remarked that as the surgeon was not at the Court in time, no entry could be made relative to his fee for attendance.—Mr. Williams said he had to complain of the way in which he was informed of cases, and stated that he had only been warned to attend the Court some forty minutes previously. Ten minutes had been occupied in giving absolutely necessary instructions to be observed during his absence from hospital, and the remaining twenty minutes in his getting to the court.—Inspector Bidgood said he warned the surgeon at ten o'clock that he would either have to give a certificate or attend the Court.—Mr. Williams distinctly denied this statement.—The Clerk: You might have given a certificate and saved all this bother.—Mr. Williams: It is not usual to give a certificate without the fee.—The Chairman: Well, the case has been adjourned for a week.—Mr. Williams: I have attended here at great inconvenience. I suppose my fee will be all right?—The Clerk: You were not here in time to give evidence, and I cannot book your fee.—Mr. Williams: But I complain of the way I am informed of cases. It has been the same with the other house-surgeons.—The Clerk: We know all about the other house-surgeons.—The Chairman: Excuse me, the case has been already adjourned, and it must end here.—Consequently Mr. Williams' enforced attendance at Court was unremunerated. Why not try the same system of unpaid services upon the legal as well as the medical profession? A commencement might be made with the Clerk of the Portsmouth Court!

London Hospital Medical College.—We are informed that Mr. Hugh Smith has obtained the Entrance Science Scholarship of £60; Mr. E. Barclay Smith the Entrance Science Scholarship of £40; Mr. L. Raby the Burton Scholarship of £30; and Mr. F. R. Ozzard the Burton Scholarship of £20, at this College.

St. Thomas's Hospital Medical School.—We are requested

to announce that the Entrance Scholarships in Natural Science at this College have been awarded as follows:—Scholarship of £100 to Mr. Horace Duncan; Scholarship of £80 to Mr. E. D. Shirriff.

University of Durham.—*First Examination for the Degree of Bachelor in Medicine.*—The following is the list of successful candidates at the examination held last week:—*First-class Honours*: No candidate was successful. *Second-class Honours*: James R. Roberts (Middlesex Hospital).

Pass List.

Archer, Edmund Lewis, M.R.C.S., St. Bartholomew's.	Mosse, Herbert, Charing Cross Hospital.
Bate, John Frederick, University College Hospital.	Newbolt, George P., St. Bartholomew's Hospital.
Blight, William Lyne.	Opie, Edward Augustus.
Dixon, Henry W., Newcastle-upon- Tyne.	Robinson, Louis, St. Bartholomew's Hospital.
Harper, John Maurice, London Hospital.	Robson, James Matthew, B.A., Newcastle-upon-Tyne.
Hartley, Isaac, Newcastle-upon- Tyne.	Thistle, Frederick T., M.R.C.P., St. Bartholomew's Hospital.
Jacques, William, Newcastle-upon- Tyne.	Woolmer, Shirley Lawrence, Uni- versity College Hospital.
Lazenby, James, Newcastle-upon- Tyne.	

Ten candidates failed in the examination as a whole. Two failed in chemistry only, and one in botany only.

Alabama, New Orleans, Texas, and Pacific Junction Railways Co.—Subscriptions are invited in our advertisement columns for £700,000 (part of an authorised issue of £1,000,000), in bonds of £100 each, bearing 6 per cent. interest redeemable at par in 1909, or previously by a six months' notice at £115 per £100. The Company, which has the complete control of about 867 miles of railways, and is in due alliance with the Alabama Great Southern Company, owns 295 miles, forming a system of 1,162 miles of trunk roads, to be worked as one system, has a subscribed and fully paid share capital of £1,500,000 in preference shares, expended in the development and purchase of the lines forming the system. The present issue of Bonds are offered for subscription at £94 per £100 bond payable by instalments.

Notices to Correspondents.

MR. SAWLER.—Bacterial fermentation is a natural process during pancreatic digestion, in all probability. It will not take place in the presence of salicylic acid, or if air be entirely excluded. Indol is the substance to which the faecal odour of the contents of the large intestines is attributed. Their colour is associated with the bile pigments.

MR. H. O. THOMAS'S paper (conclusion) on "The Treatment of Fractures of the Patella" is unavoidably held over for a wood-cut illustration.

MR. WALTER RIVINGTON (London) is thanked.

THE DUTIES OF APOTHECARIES TO IRISH DISPENSARIES.—Having been interrogated by a correspondent on this point, we have made diligent search and inquiry, and cannot find that the duties of apothecaries to Irish dispensaries are anywhere set forth. Their functions seem to be governed by unwritten law, and we believe they are Poor-law union officers, and not dispensary or medical charities' officers at all.

MR. CUTHBERTSON.—It is impossible to combine the two substances in any form of mixture. Any ordinary nervine tonic would meet the requirements of the case.

DR. JAMES R.—The subject has been previously referred to. We do not feel called upon to reopen the discussion.

A. S. T.—It has been tried, but without success. You must apply for licence on the recommendation of some person of eminence, and an authority able to judge of the value of the suggested research.

A FRIGHTENED STUDENT.—We are very sorry for you; but the fault is entirely your own. Seek advice from your teachers.

INDISCREET TOUTING.—With reference to our remarks under this heading, we are requested by the Secretary of the Kent County Ophthalmic Hospital, situate at Maidstone, to state that the person who officiously sought by a house-to-house visitation at Hastings to obtain subscriptions in aid of this Hospital was in no way authorised by the Council; and that, moreover, any moneys so obtained have not been paid in to the funds of the institution in question. The Secretary further states that "The Kent County Ophthalmic Hospital" and the West Kent Hospital are distinct institutions, both situate at Maidstone, and both doing a large amount of good; but in no case have appeals outside the county been officially sanctioned by the governing bodies, although patients from other counties frequently go to the Ophthalmic Hospital for gratuitous treatment.

M. R. B.—We cannot take the case up just now, nor do we see how you can justify action in it yourself. By your own showing you have not been aggrieved, and can therefore have no locus standi as a complainant. A personal explanation would be most likely to ensure an amicable understanding, and you ought to take the initiative.

DR. CRAWLEY has evidently been guided by mere hearsay evidence

He would do wisely to procure and study the work he condemns before passing an opinion on it. Had he consulted it before writing he would probably have quoted the title rightly, and avoided the error of ascribing language to an author of which he has not been guilty in the work referred to by our correspondent as containing the passages complained of.

CANTAR.—You are correctly informed.

A SUBURBAN PRACTITIONER.—You have an undoubted grievance, but one unfortunately very unlikely to be redressed. You are but a single individual against a powerful society, and until you can obtain a large amount of support from similarly injured members you will not effect anything to your own advantage.

IGNORAMUS.—The name is applied to those double teeth which are situated anteriorly to the molars. It is usual in anatomy to apply the term to those permanent grinders which replace the milk molars of the first dentition.

DR. KINLOCK PATTERSON (Perth).—Owing to pressure on our space we have been unable to give the necessary space to your paper. We shall probably insert it in our next, previously to which proof will be sent you as requested.

DR. J. OWEN.—You could not do better than read Prof. Hutchinson's College of Surgeons' lectures on "Temperature, Idiosyncrasy, and Diathesis in relation to Disease" which appeared in our issues for July and August of present year.

SURGEON-GENERAL FRANCOIS' "Case of Aortic Aneurism opening into the Oesophagus" shall appear in an early number.

A PUZZLED AUTHOR.—You may take the following table for guidance in the relation of metrical weights and measures to British:—

Décligramme	=	1.543 grain.
Gramme	=	15.432 grains.
Centilitre	=	10 cubic centimetres .. 2 dr. 49 m.
Decilitre	=	100 " " .. 8 oz. 4 dr. 10.3 m.
Litre	=	1000 " " .. 1.76 pint.
Millimetre	=	.0394 inch.
Centimetre	=	.3937 inch.
Decimetre	=	3.9370 inches.
Metre	=	39.3707 inches.

Vacancies.

Carlton Union, Bagenalstown Dispensary.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, Oct. 24th.
Glenties Union, Ardara Dispensary.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Oct. 24th.
Kendal Union.—Medical Officer and Public Vaccinator. Salary, £40 and £45 respectively. Applications to be sent to the Clerk on or before Oct. 26th.
Northampton General Infirmary.—Physician. Applications to be forwarded to the Secretary not later than Oct. 27th.
Oldcastle Union, Crossakel Dispensary.—Medical Officer. Salary, £50, and £15 as Medical Officer of Health. Election, Oct. 20th.
Parish of Birmingham.—Physician. Salary at the rate of £150 a year. Applications to be sent to the Clerk to the Guardians not later than Oct. 23rd.

Appointments.

CONRY, J. T. C., L.F.F.S. Glas., L.K.Q.C.P.I., Medical Superintendent to the new Infirmary at Hope, Salford.
DUNN, A., L.R.C.P. Ed., L.R.C.S.I., Medical Officer to the Portlary Dispensary District.
EAGLES, W., M.R.C.S., Surgeon to the Bucks General Infirmary.
FLINN, D. E., L.K.Q.C.P.I., L.R.C.S.I. & L.M., Surgeon to St. Michael's Hospital, Kingstown, Dublin.
GORDON, J. J., L.R.C.P. Ed., L.R.C.S. Ed., Assistant Medical Officer to the Infirmary and Workhouse, Hackney Union.
JONES, E., M.B. Lond., &c., Assistant Medical Officer at Colney Hatch Asylum (Female Department).
KING, Dr. J., Apothecary to the Peter Street Dispensary, Dublin.
MACDONNELL, M. A., M.D., M.Ch.Q.U.I., Honorary Medical Officer to the South Dispensary, Liverpool.
ST. GEORGE, G. L., L.K.Q.C.P.I., L.R.C.S. Ed., Surgeon to the County Antrim Infirmary.
STREET, A. F., M.A., M.B. Cantab., M.R.C.S., Senior Resident Medical Officer to the Radcliffe Infirmary, Oxford.

Births.

KELLY.—Oct. 5, at 12 Plough Road, London, S.E., the wife of Bernard Kelly, M.D., of a son.
POTTS.—Oct. 12, at Sunnyside, Leatherhead, the wife of Lawrence Potts, M.R.C.S., of a son.
RENDALL.—Oct. 10, at Maiden Newton, the wife of Wm. Rendall, M.R.C.S., of a daughter.
SMYLY.—Oct. 7, at 35 Upper Fitzwilliam Street, Dublin, the wife of W. J. Smyly, M.D., of a son.

Deaths.

HOLMES.—Oct. 13, at Tudor House, Lyme Regis, Thos. J. Holmes, M.D., aged 66.
LANGLEY.—Oct. 7, at his residence, Tramora, William Leale Langley, M.D., Inspector-General of Army Hospitals, aged 69.
PALMER.—Oct. 8, at 23 Clifton Terrace, Brighton, Thomas Palmer, M.D. Lond., aged 63, formerly of Radnor Place.
RISDON.—Oct. 6, at Bideford, North Devon, Robert Risdon, M.R.C.S. late of James Street, London, S.W., aged 53.
SCOTCHBURN.—Oct. 6, at Great Driffield, Alfred Scotchburn, M.R.C.S., aged 55.

WHOOPIING-COUGH: ITS PATHOLOGY AND TREATMENT. (a)

By THOMAS M. DOLAN, F.R.C.S., L.R.C.P. Ed.,
Medical Officer to the Halifax Union Infirmary.

MR. DOLAN prefaced his paper by saying it was easy to frame a definition of whooping-cough, but a recapitulation of symptoms was not an explanation. He would endeavour to throw what light he could on its true pathogenesis. He could not dwell upon all the theories advanced, but he would devote a little attention to the views of Dr. Gueneau de Mussy, in order to make them the basis for his objections against a large number of theories.

The theory of M. Gueneau de Mussy that the malady was a bronchial adenopathy, characterised by enlargement of tracheo-bronchial glands with compression of the pneumogastric, did not appear to him to account for the phenomena of pertussis. He shared in the objections raised by M. Colin, Hardy, Blot, Woillez, in the discussion at the Academy of Medicine, Paris, and by Drs. Barlow and Burney Yeo at the Pathological Society of London.

The tracheo-bronchial glandular enlargement was not always present in pertussis, and when, from various causes apart from pertussis, these glands have been enlarged, the pertussoid cough has been absent during life.

The contagious character of whooping-cough could not be explained by any theory of location in the nerve centres. Looking at all the phenomena and the symptoms, whooping-cough presented certain resemblances to those diseases, the causes of which were now believed to be minute organisms or fungi. It was highly contagious; it had its period of incubation; of effervescence

and defervescence; it ran a regular course; it rarely occurred but once in the same individual.

On the grounds of analogy, then, and some ascertained facts, he would place pertussis in the group of diseases caused by Protophytic Fungi. Linnæus foreshadowed modern views when he endeavoured to prove that almost all diseases were produced by animalculæ, or had an insect origin. The insect of Linnæus was the microbe of Pasteur: two great minds thus met at the same conclusion.

Other observers, such as Poulet, Letzerich, and Binz suggested the fungoid nature of pertussis. So far back as 1867 M. Poulet found in the sputa of pertussoid patients what were then termed Infusoria, belonging to the class bacterium—bacillus.

Letzerich had produced whooping-cough in rabbits by inoculating the trachea with sputa from the human subject. Repeating experiments like those of Letzerich on rabbits, he found that the blood did not produce any effects, but that the sputa and other secretions caused death. Microscopic examination of sputa revealed ordinary bacteroid forms, but in addition, he had observed a microbe to his eye, somewhat resembling the spirælochaete plicatilis of Cohn. He had been assured that this microbe was a delusion, and could be accounted for by the personal equation which must always be allowed for in microscopic work, viz., the desire of the observer to see in the field of the microscope what he wished to see.

Since this essay was written Koch had discovered the tubercle bacillus. Improved methods of staining, such as those of Henneage-Gibbes, and others, more readily exposed these minute organisms. By the application of similar methods he believed that the special microbe of pertussis would be revealed. Admitting the fungoid nature of pertussis, the contagious nature of the malady was easily explained. The nasal secretion and sputa, &c., contained a well-characterised toxic principle. The sputa confined this. Germs were thrown off into the air. These germs entered by some of the channels by which other contagia entered. They developed in the blood, setting up constitutional disturbance, subse-

(a) Abstract of the Fothergillian Gold Medal Prize Essay, read before the Medical Society of London, October 16, 1882.

quently attacking the pulmonary epithelium, giving rise to all the phenomena of pertussis. From the lungs the contagion was again thrown off.

In pure, uncomplicated whooping-cough the scalpel of the most practised anatomist failed to detect any characteristic or pathognomonic lesion. This was not surprising, and lent support to his hypothesis. The simple disease whooping-cough was rarely fatal; the complications killed, and were numerous. He had, as far as possible, in his essay examined the pathological state of the usual complications. Time would not allow him to dwell upon them.

It was believed that the urine was very frequently saccharine. He had examined the urine of 50 children with confirmed whooping-cough and only found traces of sugar in 13.

This theory harmonised with some of the methods of treatment advanced and rendered them intelligible. The key-note on treatment had been struck by Sir Thomas Watson. Before considering treatment he would devote some time to the question of prevention. There had been no systematic attempt made to limit, check, or stamp out whooping-cough. If it were possible on the same day to isolate all the children suffering from this disease in England, and to keep them in quarantine for a lengthened period, whooping-cough might be stamped out. This he knew was impracticable. We might, however, do much to check and limit it. Without the assistance of the public we were powerless. Contagium was what we had to contend with in whooping-cough. The public should be instructed in the general principles of prevention—these he sketched. Whooping-cough, like all the other zymotic diseases, taught us one lesson—the dependence of one class upon another. If we threw a stone into a pond a very well-known phenomenon occurred. The water was disturbed; very soon circles might be seen radiating from the disturbed centre; those circles increased, grew wider and wider, until they were ultimately lost to the perception of the eye; each circle bore a geometrical relation to the preceding circle; all owed their origin to the primary point at which the stone sank out of sight. When whooping-cough or any other infectious disease occurred, from this tainted centre waves or circles might be thrown off; those waves might increase, grow wider and wider, but different from the mimic circle on the pond, carried with them disease, misery, and death. Those waves did not respect old or young, rich or poor, the prince or the peasant. They all bore a relation to the primary case, so that each class had an interest in confining the operation of the primary disturbance. If each one discharged his individual responsibility there would be no excessive individual sacrifice; if each one considered his neighbour, how easy it would be to check infectious disease. It all followed in a consecutive chain of duty and self interest. By the isolation of the first case of whooping-cough in any house or street, by the observance of the general directions given, a limit would be put to the spread of the disease. One family would suffer a little self-denial, and it would involve a little self-sacrifice, but the general gain to the community would be great indeed.

Approaching the subject of treatment proper, he stated that the scientific physician did not pretend to cure (in the sense in which it is commonly understood) scarlatina, measles, typhoid fever, or small-pox; but, like the helmsman at the helm of a ship, he strove to guide their course, to pilot his patients safe to land—to recovery, avoiding the reefs and rocks, or otherwise, the complications which might arise. Great skill was required in this process, even though all the above diseases ran naturally towards recovery. Whooping-cough, like measles and scarlatina, would run its course. We had no power over its incubation or its development, but we had great power over its issue. As he had previously pointed out, we could by a modified form of isolation and quarantine prevent the

spread of infection. By improved hygienic arrangements we could place the patient in the most favourable circumstances towards recovery; we could relieve certain painful and prominent sources of trouble; we could guard against complications; in a word, by the employment of rational measures we could assist Nature in her efforts to throw off the disease, and this was the highest power we possessed in dealing with the majority of diseases of this class. He described a plan of treatment and gave a copious formulary. In all plans of treatment certain modifications must be made, depending on the occurrence of exceptional phenomena. Every plan of treatment must be modified to suit the age, constitution, and the environment of the patient. Thus, for instance, we could not pretend to treat a delicate, strumous infant with whooping-cough in the same way as we would treat a robust, strong, and healthy infant; nor would we use the same measures for an infant that we should employ for a child of two or four years of age. An empiric might make a fortune by announcing that he had a cure for pertussis even at the present day; and if he were to make up a mixture of bromide of potassium, or ammonium, and advertise it with the same spirit of enterprise with which Holloway and Eno have pushed their pills and fruit salt, the same rich reward would almost certainly follow.

Treating the subject from a scientific standpoint, and apart from empiricism, he was forced to agree with Dr. Dickinson and those older physicians, who taught that there was no specific, and that we must be content with guiding the disease through its course. How we may do so he had endeavoured to show, and still more, as prevention was better than cure, laid down directions on prophylaxis, which if adopted would deprive us of the necessity of having to attempt to cure it.

The latest development of the genius of Pasteur had found issue in arresting splenic fever and fowl cholera by inoculation with the attenuated virus of the microbes upon which those diseases depended, so that he might not unreasonably hope that, as whooping-cough was a bacteroid disease, we might be able by his method to add a more powerful weapon to our preventive measures, and that by inoculation with the attenuated virus of pertussis we might render infants insusceptible to the contagion.

Jenner conferred a boon on humanity by the introduction of vaccination. Following in the footsteps of the illustrious Englishman, Pasteur promised to be equally a benefactor to his race.

But was not this a sad confession to make, that we have to depend upon prophylaxis—that we had no specific? He did not think so. We could control and direct the disease, just as we controlled typhoid, scarlatina, variola. We had no specifics for them.

His views were, he believed, in harmony with the temper of medicine in modern times. It was not derogatory to true progress to recognise the Hippocratic, *vis medicatrix nature*. It was something to be able to estimate the physiological disturbance going on in virus diseases—the heat, waste, increase of heart or lung action, the altered functions of secretion and excretion; to have the power of directing or controlling physiological action, though we could not arrest or neutralise the specific organisms which are at work. It was something to know the nature of the organisms we had to deal with; it was something to feel proud of that, by the aid of sanitary science, we could prevent such diseases, though they depended upon entities which cannot be cast out after the incubatory stage.

The true pathogenesis of pertussis might not have been pointed out, yet if his views were adopted they afforded a wide sphere for activity. We could relieve certain symptoms as they arose; we could alleviate, we could palliate, and we could prevent. To counteract the causes of disease was the highest triumph of our art.

There was a true and false medicine—the true consisted in knowing how much we knew; the false in pretending that all the arcana of disease and Nature were open to us. The true was noble and honest; the false was ignoble and dishonest.

In the interest of the true it was better to unhesitatingly declare that there was no specific for pertussis, and to show the reason why. This he had endeavoured to do. In the interests of little patients he should have been pleased, had facts allowed him, to write that there was a panacea for pertussis; and when the specific was found he should hail its advent with joy, and gladly put it to the proof. It would be a pleasure, in this case, to be convinced of holding erroneous views.

Meantime, waiting for the panacea, he submitted his own method of treatment to the consideration of the profession, and, in the words of Horace, said:—

“ Si quid novisti rectius istis
Candidus imperti; si non his utere mecum.”

ON AUSCULTATION OF THE TRACHEA AND MOUTH IN THORACIC DISEASE. (a)

By DAVID DRUMMOND, M.A., M.D., T.C.D. & Durh.,
Physician to the Newcastle-on-Tyne Infirmary; Senior Physician to the Newcastle-on-Tyne Hospital for Children, &c.

In this paper it is my desire to invite attention to a physical method of examination which I have found of great service in the detection of some thoracic diseases. My method, shortly, is auscultation of the trachea and mouth. It is now nearly three years since my attention was first directed to the column of air in the large bronchi, trachea, and mouth. In the first instance it was the discovery of the fact, first observed in my own person, that violent exercise, that is to say, increased action of the heart, causes a whiff synchronous with the cardiac systole, and audible to the individual himself during expiration when the mouth is wide open, that called my attention to the subject. I was struck by this phenomenon which I attempted to explain by supposing that the arch, of the aorta, on becoming over-distended, as a result of the cardiac excitement, actually compressed the trachea at each systolic expansion, and expelled air from it, thus occasioning the whiff. I subsequently discovered that even a very slight increase in the heart's action was sufficient to produce the whiff; for example, it was developed on suddenly rising to the standing from the recumbent position; but then it was only to be heard with the bell-piece of the binaural stethoscope in the mouth during gentle expiration, and it disappeared on resuming the horizontal posture. At times there was a double whiff audible, systolic and diastolic in rhythm. I further observed that when the whiff was at all loud in the mouth, it could also be heard distinctly in the trachea.

It then occurred to me that, should my explanation of the phenomenon be correct, it ought to be present in many cases of aneurism of the arch; for the sac, in a large proportion of such cases, impinges either against the trachea or large bronchi. This I found to be the case, a fact which I communicated to the Northumberland and Durham Medical Society in October, 1880, demonstrating, at the same time, the physical sign on a patient the subject of an aneurism of the transverse and descending portions of the arch.

Briefly, the oral whiff, which I may call the sign I am now referring to, can be detected in the following manner in cases of aortic aneurism:—

The patient is directed, whilst lying on his back, to breathe as quietly as possible through the widely open mouth; the oval piece (b) of the binaural stethoscope is

then introduced into the mouth to receive the expired air. Should, then, the sign be present, the expiration will appear to be interrupted at each beat of the heart by a whiff, which in some cases is very loud, whilst in others it is only detected at the end of expiration, an indication that it is but feebly marked. In certain cases, especially if the aneurism be large, a diastolic whiff can be heard as well as a systolic. In cases in which the sign is well marked, it can be plainly heard in the trachea during quiet expirations, or when the patient is holding his breath, with the mouth open and the tongue depressed, so as to allow the gaping glottis to communicate freely with the buccal cavity. In very well marked cases, the whiff is audible in the trachea with the mouth closed, but it at once disappears when the nostrils are compressed by the fingers. In seeking for the sign, it is most important to avoid cardiac excitement; hence it should only be sought for after the patient has lain in the recumbent position for a short while, and after the reasons for inserting such a formidable-looking instrument as the binaural stethoscope into the mouth have been fully explained. It is well, indeed, to school the patient accurately before commencing the examination, for nervous, interrupted respiration on the one hand, and forcible or nasal breathing on the other, will defeat the object of the examination.

During the past two years and a-half, I have had the opportunity of examining 24 cases of thoracic aneurism, 23 of the aorta, and one of the innominate artery, 18 of which were under my own care, and 5 were under the care of my colleagues or other medical friends. Of the 23 aortic aneurisms, the whiff was present in 17; in some of which it was well marked, and in others but feebly so; it was entirely absent in 3; in one it was not sought for; and in 2 stridor and rales were so loud as to interfere with its development. The sign was altogether absent in the case of innominate aneurism. In three cases, the whiff only developed after the patients had been observed in hospital from six to eight weeks.

Before passing away from the subject of auscultation of the trachea and mouth in aortic aneurism, let me very briefly, though with emphasis, refer to another way in which the tracheal column of air may be utilised and made to furnish valuable information by means of auscultation. In many cases, aneurismal murmurs are only audible in the trachea. I have occasionally been able to diagnose an aneurism by detecting a systolic vascular murmur in the trachea at the top of the sternum, auscultation of the base of the heart in the so-called aortic area furnishing at the same time absolutely nothing abnormal beyond a somewhat muffled first sound, followed by a loud high-pitched second sound, and sometimes not even that. These vascular murmurs confined to the trachea are tolerably frequent in cases of dilated aorta and small sacculated aneurisms; in one of the cases in which the tracheal whiff was absent, this tracheal murmur was the sign which led me to a diagnosis in the absence of all basal bruits.

It is a fact worth recollecting, that nearly all systolic aortic murmurs are well heard in the trachea; but when they are much louder here than at the base of the heart, they generally mean an aneurism either fusiform or sacculated. The two sounds in the trachea—the vascular bruit and the air-whiff—are easily distinguished, for the latter disappears when the patient's mouth and nasal passages are closed, whilst the former are best heard under these circumstances.

I now come to the second, and I venture to think, the most important part of the subject. I have hitherto, in this paper, referred to simple auscultation of our air column; but now I wish to invite attention to the information gained by aural auscultation in conjunction with percussion of the chest.

The normal adult chest, when examined by the following method, furnishes certain features which I must ask your attention to. The patient sitting before the auscultator, is directed to hold the oral-piece of the stethoscope

(a) Read before the British Medical Association.

(b) I have made for me, by Messrs. Brady and Martin, Newcastle-on-Tyne, a new bell-piece, for auscultating the mouth. It is made of celluloid, and is two inches and a quarter long, and about two inches and a quarter in circumference at the end. It screws on to the binaural stethoscope.

in his mouth, and to breathe very quietly into the tube, taking care not to allow the latter to touch any part of the mouth; the observer then, with the ear-pieces adjusted, percusses the front of the chest. All over the anterior portions of the lungs, the percussion note is heard in the mouth as a clear, resonant, booming sound—a sound which can readily be imitated by holding the chest-piece of the binaural stethoscope, when it is applied to the ears, between the finger and thumb of the left hand, whilst the tube, or fingers which support it, are percussed by a finger of the right hand. Percussion over the second interspace, close to the sternum, on both sides, often produces a sharper sound with a higher pitch, which in some cases partakes of the characters of a metallic ring. Percussion at the bases posteriorly gives the same clear, resonant tone—only somewhat muffled and more distant. When the chest-walls are thin, as in a case of diabetes, the note obtained by percussing the areas beside the sternum is sharp, high-pitched, and slightly hissing, accompanied by a ring more or less amphoric in resonance—resembling, if I may so speak, the cracked-pot sound in germ.

In children with thin chest-walls, this peculiar cracked-pot-like sound can always be obtained in the second and third interspaces beside the sternum, and often indeed all over the chest. But when the child is well nourished, and the walls tolerably thick, the note is very similar to that which I have described as being characteristic of a healthy adult chest—only slightly higher pitched, more resonant, and with a tendency to a cracked metallic ring in the infra-clavicular areas. Such, then, are the phenomena elicited by an examination conducted in the way I have indicated, so far as the normal chest is concerned. The great value of the method lies in the fact that, by it, early phthisical consolidation can often be detected; and that at a stage when the ordinary percussion note, so far as the ear can appreciate it, is unaltered, and the ordinary auscultatory phenomena are very slightly, if at all changed. In some cases in which the physical sign I am about to describe pointed to early phthisis, the inspiratory murmur was just a little harsh, and the expiration was somewhat prolonged and subtubular. The suspicious sign to which I wish to draw attention, and which I venture to think will be found to be one of the most valuable and distinctive signs of incipient phthisis, is the sound heard in the mouth during quiet expiration when the chest is percussed over a nodule of consolidation, and that is a sound like the *bruit de pot fêlé* of Laennec, or the percuto-auscultatory blowing-sound of Baas. It is a sharp, high pitched, amphoric sound, exactly like the noise produced when a cracked teacup, held by the handle, is tapped sharply with the pulp of the finger, whilst the bell-piece of the binaural stethoscope is allowed to transmit the sound from the ears, with the addition of a hissing termination. This sound is only audible to the auscultator with the tube in the patient's mouth; it cannot be made out—I speak now of the sign as it is discovered in an early case of phthisis—by the method usually employed in order to demonstrate the cracked-pot sound. It is most frequently observed in the intercostal spaces at each side of the sternum, between the cartilages of the second, third, and fourth ribs; but I have also detected it in other portions of the front of the chest. It is true that this sign is closely allied to, if not almost identical with, the cracked-pot sound; indeed, they are probably dependent on the same cause, only, if I may be allowed the phrase, it is a much earlier manifestation of it, and I think possesses a significance as a diagnostic sign of early phthisis hitherto unattached to the cracked-pot sound.

The following brief details of a case in which a diagnosis was arrived at by this method will serve to exemplify its value:—

J. B., æt. 25, a coalminer, was admitted into the Newcastle Infirmary in the beginning of May of the present year (1882), complaining of cough and nocturnal perspirations of six weeks' duration. He stated that he had not lost flesh. On examining his chest, it was found

that there was no flattening, and that both sides expanded equally. The ordinary percussion-notes on both sides were normal and alike. The inspiratory murmur on the left side in the infra-clavicular region was slightly harsh and interrupted; the breath-sounds on the right side appeared normal. With the stethoscope in the mouth, percussion over the left lung in the second interspace, an inch or two from the sternum, produced a very distinct metallic hissing sound, whilst, on the right side, the note was barrel-like and normal. The patient was lost sight of for a time, but, twelve weeks subsequently, the following points were noted:—He had lost a few pounds in weight; the cough and night-sweats still continued, and he had a white frothy expectoration.

Physical Examination.—There was distinct flattening beneath the clavicle on the left side; the percussion-note here was dull and high in pitch as compared with the corresponding area on the right side. The inspiratory murmur in the infra-clavicular space was harsher than before, and almost puerile. The expiratory sound was prolonged. Auscultation and percussion of the right side were still normal. The sounds in the mouth remained unchanged.

Time will not permit me to enter at all fully into the advantages of this method of examination in the diagnosis of other thoracic diseases; but I must claim the indulgence of the members whilst I refer very briefly to the results of my experience of the method in a few other conditions.

Oral auscultation, in conjunction with thoracic percussion, will be found to be very useful in the diagnosis of pleural effusion. When the fluid-containing portions of the chest are percussed, there is an exceedingly short, high-pitched and distant sound heard in the mouth, resembling closely the muffled sound that is heard when the ear is pressed against a stone wall, whilst some one is tapping with the knuckle at the other side. In pneumonia, on the other hand, the sound is somewhat lower pitched, much louder, and more resonant. I have found the method very useful in distinguishing between fluid and caseous pneumonia, two conditions very often confounded by the similarity of their physical signs.

In cases of thickened pleura the note is muffled and high-pitched; whilst in pneumothorax it is very loud and resonant, like tapping an empty barrel. Of course percussion of the posterior regions of the chest must be practised by an assistant.

In conclusion, allow me to commend to the attention of clinical workers the column of air in the trachea and mouth, for my experience has taught me that we have therein a mine of wealth hitherto almost unexplored.

ON THE TREATMENT OF FRACTURES OF THE PATELLA.

By HUGH OWEN THOMAS, M.R.C.S.

(Concluded from page 302.)

UNTIL experience led me to a rule of treatment that commands success, I believed that no matter what plan was followed in the treatment of fracture of the patella or olecranon, a large percentage of failures was inevitable. Now, I find that by adherence to the simple rules here laid down, success is nearly certain in both these forms of fractures; no matter what method of direct or indirect fixation of the fracture be practised, success can nearly always be attained by attention to the practical details here advised. The best mode of carrying out the principles I have laid down may fairly be left to the judgment and ingenuity of the individual practitioner. Any one of the numerous forms of appliances which are generally used when posterior fixation of the lower limb is required, can be made to answer the purpose. For many years I have preferred to use in cases of fractured patella either my "calliper" or "bed-

knee" splint. If there should be much effusion *within* the joint, this is immediately removed by aspiration, and if time and opportunity permit, I at once apply to the sufferer's limb a suitable calliper (Fig. 2), thereby securing advantages and avoiding much subsequent trouble. The limb is thus early and safely secured, and the patient is ready to move about, without harm to the injured part, so soon as the pain passes away. But if a calliper of the right length be not at hand (the size of the groin ring, provided it be large enough, is of no moment), then a "knee-bed" splint is selected (Fig. 1), in which the whole limb is placed. I next apply an adhesive gaiter to exercise retention of the limb in the splint, as shown at G in the accompanying illustration. To the bandages that secure the retention plaster, just below the patella, is sewn a piece of elastic webbing, which has adhesive material spread upon the upper half of the length D, this being fixed below the patella, is stretched over it, and the adhesive portion of the elastic is applied to the middle and anterior surface of the thigh, above the upper fragment of the patella at A, which it thus constantly draws gently down and exercises also slight surface pressure over both fragments of the knee-cap, pressing them into the space between the two condyles of the femur and head of the tibia, a cup, &c., ready at hand to receive them. Now the bandage is applied at B and C, and finally the popliteal support F is placed in position and secured tight enough to hinder any downward strain of the knee-joint which would soon be unbearable. If a calliper-splint has not been employed at the onset of treatment it is better to apply one as soon as possible, the bed-splint being more applicable to the early treatment of fracture of the thigh-bone than to that of the patella. As soon as the calliper-splint is well fitted the immobility of the fracture is nearly absolute, without much circular compression of the limb.

Fig. 1. shows the bed-splint applied. Fig. 2. shows the calliper-splint fitted to the boot.

It is announced that the report made by Dr. Barry to the Local Government Board on the outbreak of typhoid fever at Bangor has been received by the sanitary authorities of that place. Dr. Barry has no hesitation in ascribing the outbreak to the water supply.

MINOR SURGERY CASES IN COUNTRY PRACTICE IN BYGONE TIMES.

By G. KINLOCH H. PATERSON, M.D., M.R.C.P.,
L.R.C.S. Ed., &c.,
Perth, N.B.

No doubt there is much sound sense in the words, "Prevention is better than cure," often expressed as these are; but surely something more than ordinary ought or might be said in favour of Minor Conservative Surgery; in support of which, and preferring to look on the bright side of the latter, the following cases, though occurring as they did in years gone by, may not be unappreciated or found uninteresting. First, then, on injured thumbs by machinery.

CASE I.—J. A., æt. 11, being with his mother in a small cot-house, or pendicle, with a certain number of acres of land attached to it, and in the barn of which, where what are called the "fanners" were working, he had unwittingly put the fingers of his right hand in about the wheels when in operation, and in one of the niches and teeth of these his thumb was crushed. I was called soon after the accident happened. On examination I found the bone on either side of the first phalanx comminuted considerably, for on applying my fingers gently, the yielding bits of broken bone were felt easily. There was no laceration, and very little abrasion observable externally. My treatment was, first, to adjust the comminuted bits of bone as well as I could, and after doing so applied very thin limber splints, moistened in warm water first, on either side of and above and under the thumb (from parts of an empty, clean, ordinary match-box), fixing and securing these well with narrow strips of cotton rag, and lastly, over the point of the thumb (backwards), above and underneath; then, with a bandage carefully rolled round over all; after which I placed the hand in an easy position. On the following day wetted with warm water, the dressing only, all round. By the third, the thumb having rather an offensive smell, moistened the dressing with a spirituous lotion of myrrh. Continued repeating the same from time to time until the fifth day, then partly dressed the thumb, allowing the splints, &c., to remain on undisturbed up to the eleventh day; then undid or took off the matted dressing and splints, and redressed it in the same way, with the latter renewed. By this time feeling and motion in it were observable, and after this it required little more except proper care and attention. Eventually the thumb became well, and as useful to the little fellow as it was before to hold the pen, book, or pencil, at the parish school.

CASE II.—W. S., a boy, about the same age (in twelve months after above one), also happened to meet with, in the same way, an exactly similar accident, and also to the thumb. I made no difference when I saw it in the treatment, and it, too, did well, with no loss of power or sensation.

CASE III.—W. L., æt. 57, farmer, in returning home in the afternoon on foot with a friend from the weekly corn market held in Perth, about six miles off from where his farm was, had got up on and in a standing position behind a dog-cart, and ere it had gone very far, the horse had shied at something, in consequence of which he fell on the turnpike road, on a part of the latter where, shortly before, road metal stones had been laid, with his face downwards. My services were, very quickly after the accident happened, requested. When I saw him a good quantity of blood had oozed away. In appearance he was in a faintish state, and considerably stunned also, though quite conscious. In falling his nose was much disfigured and injured by the sharp and small road metal stones, the integuments on each side of which hung down in narrow strips beyond its natural point; the cartilaginous part was divided right across, close to the nasal bones. Immediately adjusted (previously making sure that there were no particles of sand, &c., adhering to the parts) the driven down segments to their natural positions

again, and cross and lengthwise strapped carefully the divisions together, bringing round the point of the nose a narrow, firm band, to hold it well *in situ*, outward dressing moistened with warm water, and then after a little he was put to bed. When visiting my patient on different days afterwards, I was very doubtful at times, as he lay in bed with his blackish nose and unpleasant aspect of his countenance altogether, as to how it might end. Notwithstanding, I did not remove the whole of the dressing in a hurry; I only smeared over it from time to time means of an oleaginous nature, which had a good effect in loosening gradually the matted and blood-clotted hard crust, and as soon as seemed possible and safe removed, a week after, bit by bit only of the outward dressing, putting on fresh afterwards moistened in warm water, and a stimulating lotion gently sprinkled over it. In about fourteen days from the occurrence the previously denuded parts of the nose appeared very favourably; in another week, and after cautiously removing the whole of the dressing, my prospects were considerably increased, from the pleasing way it looked; fortunately, no erysipelatous inflammation had ever shown itself. During the treatment he was ordered to be kept quiet for the first few days, his diet of a mild farinaceous nature, warm drinks *ad libitum*, with no alcohol internally. By another week, the end of the third, the healing process had still advanced very much, and so favourably, that ere long the nose looked again whole and well shaped, as good-like as it was before.

It is said, "meddlesome midwifery is bad;" so I take it oppositely, as the same—though in a different sense—may be said in reference to certain cases of minor surgery. In my cases given at present I used simple, but efficient, applications, &c., with proper and timely attention afterwards. I may, however, make the following statement:—The blood-clotted, hard, crusty state of the dressings in each case which followed, and on account of these interposing substances seemingly, by excluding the surrounding air, were greatly influential and favourable to hastening (not hindering) Nature's curative processes, or modes of healing. At the same time I may state that I am far from wishing to under-estimate Lister's method, or antiseptics either, for if these had been discovered and recommended in the times my cases occurred, I would certainly have availed myself of one or other of these where I thought required. Notwithstanding, when glancing back upon the past, or at the present, who can fail, while inwardly reflecting, to be cheered onwards, from the many available resources we have now at our command than formerly? and who can overlook the vast amount of good throughout the wide medical world—almost from pole to pole—these have already done, and further well calculated yet to do, through members of the profession—men who have risen to greatness by the force of their genius, while others also are rising from the noble use of their perceptive powers, along with study and perseverance, and who have found out very important and valuable means to assist in the relief of suffering humanity and cure of disease. Also looking to a brighter future from the great progress within even the past few years, we have every reason to hope for and to expect great achievements in medical science. May each one of us, therefore, feel it to be not only his duty, but his earnest desire, to go onward and likewise try to give his share of contributions towards the literature of medical knowledge, so as to ennoble still further the profession we belong to, willingly joining in every well-meant efforts possible for good, and by unceasingly and mutually cherishing the noblest feelings implanted in and akin to man. Onward, then; let our motto be for greater achievements, surgical, medical, &c., &c. meanwhile, and as hitherto, endeavouring to be found, when called, right worthy and true helpers, as well as skilful workers, in the hour of need, while happily and truly afterwards, and always, finding that when each has been able to "act well his part, there all the honour lies."

Clinical Records.

NEWCASTLE-ON-TYNE GENERAL INFIRMARY.

Genu Valgum—McEwen's Operation—Recovery.

Under the care of Dr. ARNISON.

Reported by JAMES LIMONT, M.B., Senior House Surgeon.

H. S., *æt* 16, bottle-washer, admitted March 23rd, 1882, suffering from knock-knee, said to be of four years' duration. When standing, patient places one knee behind the other, and in walking rubs one over the other. His gait is slow, laboured, and unsteady. The internal femoral condyles are much lengthened, and the lower third of the femur is bent forwards and inwards.

March 28th.—Both femurs were divided according to McEwen's method. The bones were very hard, and the osteotomes had to be re-applied several times before the bones could be broken. The limbs were dressed with the ordinary antiseptic dressings, the operation being done under the spray. An elastic band was employed to empty the leg of blood, and on removing this after the bone was divided, there was merely a slight oozing of blood which stopped immediately. A long side splint with a back splint was applied to each limb, the two side splints being connected by a cross-bar. Patient was placed on a mattress of four pieces, one of which was withdrawn when the bed-pan was required, and thus all movement of patient avoided.

May 17th.—Since operation temperature has never risen to 100°, and has been normal after the first two days. There has been no pain or discomfort. The dressings were removed to-day for the first time; both incisions were found to be healed, and bony union pretty firm.

29th.—Patient walks about with aid of crutches.

June 7th.—Left hospital, walking without crutches. The legs are perfectly straight—the internal malleoli touching one another when the internal condyles are in apposition.

Genu Valgum—McEwen's Operation—Recovery.

Under the care of Mr. PAGE.

Reported by W. G. BLACK, M.R.C.S., Junior House Surgeon.

ETHEL CANTLISH, *æt* 7, admitted into the Infirmary on June 22, 1882, suffering from knock-knee. On examination in the erect posture the deformity was very marked, the internal malleoli being separated for 15 inches; the right tibia was thickened, and presented a well-marked spine; left was normal.

On June 27th supra-condylloid division of the femur was performed under antiseptic precautions, both femora being divided with M'Ewen's chisels; the limbs were straightened, dressed, and placed on M'Ewen's box-splint. The temperature the day after the operation rose to 101.3, but after this all went well, and the limbs were not disturbed until August 6th, when the dressings were removed. The left limb was found to be strong, the fracture united, and the wound healed. Right limb was not firmly united. The limbs were kept on the splints for another week, and then the child was allowed free movement of them in bed.

She left the Infirmary on August 26th, 1882, perfectly cured.

Special.

THE RUSSIAN MEDICAL PRESS.

DR. O. PETERSKY, of St. Petersburg, recently forwarded a very interesting account of the Russian medical press to the *Deutsche Med. Zeit.*, from which we translate the following interesting particulars:—

Until the commencement of the last decade the Russian periodical medical press was still in its infancy. Many attempts were made to publish medical journals, but with the result that most of the attempts were failures, or they only succeeded by the aid of subventions on the part of the Government. Of the journals that have already passed

away may be mentioned the *Moskowskye Medizinskaja Gazeta*, (*Moscow Medical Times*), which was in existence for a number of years and passed away in 1877. Besides this there was a journal of pathological anatomy, published by Prof. Rudnew, which closed its existence in 1876.

Amongst those still existing are—

1. *Wojsuao Medizinske Journal*, (*Military Medical Journal*). This is the oldest. It has been in existence many years and is published by the military authorities. At present Dr. R. Koslow and Dr. U. Iwanow are the editors. All military medical officers are compulsory subscribers. This journal which appears monthly in thick parts is by no means, as may be imagined from the title, a purely military one. It contains articles out of the domains of anatomy, physiology, pharmacology, hygiene, pathology, and therapeutics, whilst articles that relate to purely military sanitary affairs are relatively infrequent. For a long time almost all the greater works were published exclusively in this journal. Short extracts from foreign works, and translations of whole works appear as supplements. In this manner every subscriber receives yearly three or four large valuable handbooks translated into Russian. The Minister of War publishes in this paper the orders of the day for military medical officers, and the promotion list pays a not inconsiderable subvention yearly. A re-organisation is at present in progress, and the question to be decided is whether the journal is to be handed over to the medical academy or to an "Arrondator."

2. Of almost the same age as the one just mentioned is the *Westnik Snudebnoi Medizini & obschtschestvennoi Gigieni* (*Forensic Medicine & Public Hygienic Messenger*), which is published by the medical department of the Ministry of the Interior, and is obligatory for all city and district medical officers as the official orders are published in it. Dr. Schwelaw is the editor. This journal, a quarterly, up to the present year bore a title showing that it was edited by the Ministry. The programme has also been somewhat modified. At present it brings out long works on the subjects embraced by the title, and in addition are articles treating on pathology, therapeutics, epidemiology, medical statistics, and medical geography. A supplement gives also extracts out of the domains of general medicine, or translations of whole works.

Of later origin are the following:—

3. *Medizinskoe Obshrenje* (*Medical Circle*), of which the editor is Dr. Sprimon. It appears monthly and contains, besides extracts of a practical nature, short able original articles, and meets with much approval.

4. *Sdorowje* (*Health*), has appeared since 1875. Its editor is Professor Dobroslawin, of St. Petersburg. Up to the present year it was a hybrid, a half popular, and half scientific weekly. As such papers never succeed it has been converted into a purely scientific monthly.

5. *Wratschebuija Wjedomosti* (*Medical Times or Journal*), a weekly, has been in existence since 1876. It is edited in St. Petersburg by Dr. Iljinski. It was also originally a popular paper, but was soon re-organised into one that is purely scientific, and it is now the principal organ for the country medical men. It contains reports of their various meetings, original matter, and extracts, and has mainly a practical character.

6. *Iztopisy Moskovskago Chirurgitscheskago Obschestwa* (*Annals of the Moscow Surgical Society*), is edited by Dr. Markonet. It contains reports of society meetings and appears monthly.

7. It was a happy thought of Professor Manasseu when he undertook [the publication of his *Wratsch* (*The Physician*). This weekly publication has, in a short space of time, been distinguished by a success that has never been met with by any other medical periodical in Russia. This has been due in part to the ability and activity of the editor, and in part also to the character and style of the publication. It is a double sheet, and contains, besides a large amount of original matter, embracing the whole range of clinical medicine and hygiene, a large number of extracts, and thoroughly follows up medical interests and events. Notwithstanding its youth it has the widest circulation of any medical paper in the country.

Latterly the medical press has been particularly active. For the year 1881 the appearance of three new papers has to be chronicled.

8. *Medizinskaja Bibliotheka* (*Medical Library*), the editor of which is Dr. Popow (recently Dr. Aurep). It contains principally translations of foreign works, but not to the exclusion of Russian.

9. *Wojsno Sanitarnje Djelo* (*Military Sanitation*), editor, Dr. Goldenberg. A St. Petersburg weekly paper, for officers and physicians.

10. *Jeshenedjelnaja Klinitscheskaja Gazetta* (*Clinical Weekly Gazette*), published by Professor Botken and edited by Dr. Sokolow. It is mainly devoted to "Kasui-tik" and only exceptionally contains extracts or criticisms on particularly important works.

The present year has brought with it three new publications.

11. *Meschdunarodnaja Klinidka* (*International Clinique*), Professor Slavjansky editor. It has arisen through the publication of a translation of the *Wiener Klinik* and appears in monthly parts. It contains translations and original clinical addresses.

12. *Doktor*, the editor of which is K. Skurchowitsch, a popular medical journal. It is published in Kischinew.

13. *Medizinski Westnik* (*The Medical Messenger*), editor Dr. Swjatlovsky, of St. Petersburg. Twenty years ago a journal was published with the same name which in its day was a paper of importance, but it unfortunately came to an end last year in consequence of the death of its very able and gifted editor Dr. Dmitrovsky.

14. *The Westnik Wodoletschenija* (*The Hydropathic Messenger*), which appeared last year, enjoyed but a brief existence. But twelve monthly parts were issued. It was published by Dr. Lewis, and edited by Dr. Galanin, and during its year of existence brought out a series of very interesting articles on the "Waters" of Russia.

A few publications may still be mentioned which appear regularly:—

a. "Archiv Kliniki Wuntrennich bolosnei" ("Archives of the Medical Clinique"), of Professor Botkin. It is mainly composed of dissertations written under his direction.

b. "Medizinski Sbornik Imperatorskawo Kawkaskawo Medizinskowo Obschtschestwo" ("Medical Messenger of the Imperial Caucasian Medical Society"). Two to three numbers are issued yearly.

c. "Trudi Obschtschestwa ruskich Wratschei w Peterburge" ("Proceedings of the Russian Medical Society of St. Petersburg") appears three times a year.

Besides these the Foundling Hospitals in St. Petersburg and Moscow publish very able annual reports. In the same manner appear the published proceedings of various

societies, for example, those of the Physicians of Kasan, Charkow, Woronesch, &c.

In addition to those mentioned above appear a considerable number of German publications. One of these, the *Deutsche Wochenschrift*, commenced over forty years ago, and was long subsidised by the Russian Government. After the withdrawal of the subsidy it experienced the usual fate.

In conclusion, it may be affirmed that medical science is at present in a flourishing state in Russia. Its literature is becoming more developed year after year, and the number of Russian handbooks and original works is constantly on the increase.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, OCTOBER 25, 1882.

THE ROYAL COMMISSIONERS' REPORT ON SMALL-POX AND FEVER HOSPITALS.

ALTHOUGH we cannot at the present time do more than briefly note its appearance, the publication of the Report prepared by the Royal Commission appointed to inquire into the accommodation existing in the metropolis for small-pox and fever patients is far too important an event to be passed entirely without comment. It would not probably be estimating it too highly to describe it as of the utmost interest in connection with future arrangements for meeting the strain created by epidemic fevers; and to every resident in or near London it must be more or less directly pregnant with good or ill consequences.

The work to be accomplished by the Commission has been well and fully carried out. Sitzings extending

over thirty-seven meetings have been held, and no fewer than forty-eight witnesses have been examined. Among those, moreover, who have been called upon to give evidence are found representatives of widely-different opinions respecting the hospitals hitherto in use, and the dangers and advantages arising from them; and one of the most deeply interesting portions of the Report is that in which adhesion is practically given to the supposition widely held that small-pox hospitals are veritable centres of infection. In this connection the evidence afforded by Mr. Power, an inspector under the Local Government Board, will be read with all the attention it deserves to receive; and it will probably serve to convince those who may be doubtful of the fact, that cases of small-pox are encountered with greater or less frequency and severity in the vicinity of small-pox hospitals, accordingly as these are or are not crowded with cases. Objections may not improperly be taken to conclusions thus drawn, on the score that a numerical increase in cases would be observed in any district *pari passu* with growing epidemics. But careful consideration of the comparative tables illustrating that portion of the Report dealing with this subject will show that such courses of error do not destroy the validity of the conclusions arrived at, since whatever would operate in this direction is eliminated or provided for by further explanations. As it is, small-pox is unquestionably influenced as to its occurrence in a neighbourhood by the presence in that neighbourhood of a hospital for the reception of patients suffering from the disease. The exact nature of the influence, however, requires to be yet more definitely determined, although the Report is tolerably positive in its assurance that administrative arrangements have little to do with the dissemination of the disease. In accordance with this view, we have a suggestion for limiting the number of beds at each isolation centre to about thirty or forty. Should this proposal be completely adopted it will, of course, put an end to large aggregations of small-pox cases against which so much and frequent complaint has been made; and if at the same time there is carried out the reform sketched out in the Report with respect to steps to be taken to isolate infected patients, then manifold benefits must result. We shall not look in vain in the future for such measures to be put in force as shall render it impossible for scandals to arise similar to those which have been so familiar to us in the past, in connection with transmission of patients suffering from infectious fevers. Under the authority to be properly constituted, such removals will be conducted with every precaution in behalf of public safety; and in this relation the Report deals with the question of notification of disease. The Commissioners are of opinion that arrangements should be made for ensuring that the medical officer of health in every district may be immediately informed of the outbreak of infectious disease. The duty of conveying such information they would impose upon the householder or occupier in every case, except when the patient is a pauper, and then by the medical attendant, to whom the payment of a small fee for carrying it out is recommended. For

the purpose of securing isolation wherever such a proceeding may be demanded, the Commissioners would give the sanitary authority power to clear a house of all other inmates but the patient and his attendants; and compensation for disturbance is allowed to find a place in the outlines of this scheme.

For many reasons the suggestion that in dealing with persons suffering from infectious disease the distinction between pauper and non-pauper should no longer be drawn, is an excellent one. So long as the question of treating a case of infectious disease, whatever may be the patient's social position, is made anything other than the all-important one of isolation from the uninfected, so long will any system that is adopted be open to criticism through its weakness. One of the greatest drawbacks experienced in the past has been that attendant on a multiplicity of authority; for this, however, the Commissioners would substitute a single sanitary board, within whose jurisdiction would come every case of infectious disease occurring in the metropolis.

The extent of accommodation suggested as desirable is sufficient to receive 3,000 fever patients and 2,100 small-pox cases, which in times of emergency might be increased to 2,700. Existing hospitals are advised to be made mainly receptacles for fever cases; and convalescent patients are recommended to be sent to situations on the river, or into the country.

The Report, as we have said, is of a most important character; it is also an exhaustive *résumé* of the conclusions suggested by evidence given before the Commission, and by witnesses than whom none more capable and experienced in the questions for discussion could be named. That it will be followed by changes and improvements of high signification to London and Londoners cannot be doubted.

THE FORMATION OF MUCUS.

BEING dissatisfied with our knowledge—or rather our want of it—on the subject of the formation of mucus, and of the effects of drugs thereupon, Professor Rossbach, whose translation from the Maximilian University to Jena we recently chronicled, has been making an experimental inquiry into the subject. The results obtained have been made public in a series of contributions to the *Berliner Klin. Wochenschrift*, and in an essay specially written in honour of the tercentenary of the Würzburg University. The experiments consisted in laying bare the tracheæ of animals, first observing the phenomena of normal secretion of mucus, and afterwards the changes brought about on the application of the various drugs employed. The animals experimented on were mostly cats. He observed that in the normal state the mucous membrane was always covered by a thin layer of mucus. This persisted even when large quantities of atmospheric passed over it; and when wiped gently off with blotting-paper, within a minute or two the layer of mucus again reformed, but never so that it collected in drops or flowed down. From this observation Prof. Rossbach concluded that the mucous

membrane does not secrete constantly, but that when the secreted mucus has become reduced in quantity by evaporation, then an irritation that leads to secretion reaches the glands. It is also probable the secretion is not uniform in regard to its constituents, but that that portion which is secreted last is watery and alkaline, and serves to hold the already secreted mucin in solution. The secretion contained no sugar-forming ferment. The purposes served by tracheal and bronchial mucus the Professor states to be as follows:—(1) To keep the air-passages moist and shield them from inflammation; (2) to secrete no more fluid than is necessary to keep the passages moist; (3) to catch and hold firm inspired foreign and injurious particles, so that they do not enter the system. According to the experiments, no central nervous current—or but a feeble one—is conveyed to the secretory glands of the larynx and air passages; the secretion goes on in a perfectly undisturbed manner after complete exclusion of all extraneous nervous influences. On the other hand, vaso-motor fibres pass through the laryngeal nerves to the laryngeal mucous membrane, and the secretion of mucus has a "certain connection" with the vascularity of the mucous membrane.

The effects of cold were observed. A hot poultice was first applied to the animal's body, and this was suddenly exchanged for an ice-bag. Half-a-minute after the application of the ice, the whole mucous tract of the larynx and trachea becomes deathly white, from universal contraction of the blood-vessels. In the course of from one to two minutes this gradually ceases, to give place to a relaxation, which, when most pronounced, is distinguished by a deep bluish-red colour. At this stage such great quantities of mucus are secreted that they flow down. If the ice is now removed, and the hot poultice replaced, the change is almost instantaneous from the blue-red to a red colouration. Fresh applications of the ice again give rise to vascular spasm, but more slowly, and to a lesser degree. Rossbach considers these phenomena to be direct reflexes from the application of the cold.

Interesting as are these experiments from a physiological and pathological point of view, those relating to the action of drugs are not less so to the therapist. The introduction of alkalies into the blood, contrary to the generally accepted belief, retarded the secretion of mucus, and finally stopped it. No effect was observed during the local application of alkalies; for example, by inhalation. Diluted liquor ammoniæ and diluted vinegar painted on the mucous membrane both gave rise to great hyperæmia and increased secretion of mucus. The astringents he experimented with were alum, tannin, and four per cent. solutions of nitrate of silver. These caused a dimness in the epithelial covering, and a complete cessation of secretion. The dimness invariably produced by the astringent rendered it impossible to observe the changes wrought in the mucous membrane.

The results obtained with oil of turpentine were as follows: Air saturated with turpentine vapour, and blown upon the mucous membrane, caused the secretion gradually to diminish and finally cease, but on withdrawal

of the irritation the secretion again set in. If, on the other hand, a watery solution of turpentine was brought into contact with the mucous membrane, an increase in the secretion of mucus was observed, with a simultaneous diminution in the vascularity of the membrane. According to this experiment, oil of turpentine is a valuable remedy in chest diseases, for it at one and the same time acts anti-pyretically (contracts blood-vessels) and increases the mucous secretion, and thereby renders expectoration easier; in addition to these two actions it is also an antiseptic, in cases in which the sputa are purulent. Agents that directly excite, and to some extent greatly increase the secretion of mucus are apomorphia emetine and pilocarpine. The state of vascular fulness of the mucous membrane was not changed by these drugs. Rossbach distinguishes these three agents as expectorantia (*κατ' ἐξχρήν*). For practical purposes he mainly recommends apomorphia, as it is generally well borne, does not produce nausea, nor disturb the appetite. Pilocarpine he does not recommend, on account of its inseparable effect on the secretions of the salivary and sweat glands, and upon the heart. With regard to emetine he is not in a position to speak so positively; he is of opinion, however, that the dose of ipecacuanha usually administered is much too small.

The direct opposites of these drugs are atropia and the allied alkaloids. He has been able to verify the fact that under the use of atropia the mucous secretion gradually diminishes until the mucous membrane becomes perfectly dry, but at the same time the condition of vascular fulness increases, as may be also observed clinically, when the too copious secretion gradually diminishes and a consequent relief to cough takes place. The narcotic action of atropia he found to be very uncertain. Morphia belongs to this group. Under its use the secretion of mucus was diminished by about one-fifth, and a very considerable lessening of the cough took place. A complete cessation of bronchial secretion was never brought about by morphia, as was done by atropia.

He has also made experiments on the simultaneous exhibition of morphia and atropia. His results, obtained both by experiments on animals and in practice, are exceedingly favourable. He says of hydrochlorate of apomorphia, that given in doses of from 0.005 to 0.01 grm., so that the daily quantity administered amounts to 0.03 grm., either to children or adults, it will change a dry, tormenting cough into one that is infrequent and moist, and in which expectoration is easy; sometimes a smaller quantity will suffice. More is rarely required, although he has given as much as 0.06 grm. in the day. It is best to begin with 0.03 grm. daily, and then more or less can be given according to the requirements of the case. If vomiting should occur it will be of no consequence. Given subcutaneously, doses of from 0.005 to 0.01 produce vomiting. Apomorphia seems also suited to take the place of morphia in phthisis.

According to Rossbach's experience, the following seems the best method of administering the drug:—

R. Apomorphini hydrochlorici, grm. 0.03-0.05;
Acid. hydrochl. dil., grm. 0.50;
Aq. distillat., grm. 150. M.

Divide in vitro nigro. S. 3ss. 2dis horis sumend.

The combination of morphia with apomorphia renders the cough less troublesome, and the sputa more liquid. He prescribes as follows:—

R. Morph. hydrochl., grm. 0.03;
Apomorph. hydrochl., grm. 0.03-0.06;
Acid. hydrochl. dil., grm. 0.50;
Aq. distillat., grm. 150. M.

Divide in vitro nigro. 3ss. 2dis. v. 4tis horis.

The simultaneous administration of morphia and atropia is incorrect, i.e., in the same mixture. They are best given separately. The atropia should be given in the evening, from 6 to 10 o'clock, at intervals of two hours; two doses of the morphia mixture to be given during the same hours; but in the daytime the morphia should be given alone, according to need. He prescribes them as follows:—

R. Morph. hydrochl., grm. 0.02 to 0.05;
Aq. distillat., grm. 120;
Syr. rubi Judæi, grm. 30. M.
(Syrup of raspberries.)

D. s. 3ss. 2dis vel 4tis horis.

R. Atrop. sulph., grm. 0.0005;
Pulv. et succ. glycyrrh., q. s. M. ft. pil.
i. vel ij. vel iij. vesp. sumend.

Dr. M. Wernther has also been investigating the therapeutic effects of apomorphia, and confirms the statement of other observers that the irritable cough at the commencement of a bronchial catarrh is very much diminished by it, and that expectoration is rendered easy. It had been already recommended by Jürgensen in catarrhal pneumonia. Dr. Wernther reports a case in which a patient suffering from pneumonia was so ill that oedema of the lungs had set in, and suffocation was imminent. A mixture containing apomorphia 0.2 grm., water 100 grm., was prescribed, of which the patient was directed to take 1 tablespoonful every hour. In the first three hours he took three spoonfuls, in the fourth hour two tablespoonfuls at a dose. He then became faint, the breathing got worse, and he felt as if choking, until at last a large quantity of mucus was got rid of, and the patient recovered. It appears to owe its value mainly, or at least to a great extent, to the great power it possesses of promoting the secretion of fluid non-viscid mucus. As an emetic it possesses the advantage over all others, that even when large doses are given but little or no collapse is associated with its emetic action.

THE ARMY HOSPITALS IN EGYPT.

A CAREFUL analysis of statements made by soldiers and others recently returned from Egypt seems to throw a good deal of light upon some points that have hitherto been somewhat doubtful with regard to the hospital establishments during the late military operations in that country. It is satisfactory to find that the farther inquiry is pushed the more the circumstance is established that individually and as a body the medical officers worked zealously and well, as indeed they have ever done in times of war. But devotion and zeal on the part of individuals is not to be taken as im-

plying successful working of any particular system with which they may be connected, and it is to the system of hospitals that the present remarks refer. The facts therefore appear to be these:—The rapidity of the advance, and the brilliant success of the military operations “perforce” (so it is stated) converted what was really only a field hospital into what was wrongly called a base hospital at Ismailia. That is to say, the hospital arrangements for a mobile force, by reason of the “system” under which they had to be made, were of themselves so immobile that the force marched clean away from them. Some of the results of this arrangement were that the establishment for “field” hospitals could not “perforce” take the field, for which purpose it was by its composition fitted, and where it was most needed; in the absence, at the time indicated, of an effectually organised “base” hospital, the establishment fitted, and by its nature intended for mobility in the field, had to perform the functions of a “solitary” hospital, for which it was not originally intended or adapted. Means of transport for the mobile portions of the hospital establishment are declared to have been inadequate. This being the case, it does not appear in what manner they could have followed the troops, in the rapid advance of the latter, even had they not been converted into fixed institutions as they were. The *personnel* of the hospital establishments appears to have been insufficient; nor does it appear that means existed of increasing its efficiency by drafting men from regiments during the emergency, as frequently used to be done on similar occasions. It would appear that there having been no officer whose special duty it was to see where medical stores and equipment were stored away on board of ships leaving England, the inconvenience thus caused indicates the propriety of this duty being seen to on future occasions. These defects are the more distinctly brought out when contrasted with the efficiency of the medical department attached to the Indian portion of the force; and the circumstance is not a little strange that so little has hitherto been said or written to give the latter the credit justly due to it.

The question naturally arises, in what way are the defects above noted to be best guarded against or avoided in the future? No doubt it is very necessary that a liberal equipment be given to the hospital service, but it is fully as necessary that the distribution of that equipment should be such as to make it at any time available for the use of any portion of the force operating anywhere, including rapid advances and “brilliant successes,” for the latter are normal incidents of war in which British troops take part. In war, however, it is not by “independence” of one branch of the service over another that success in the working of a particular branch is best ensured. On the contrary, long experience has fully shown that the great essential to general success is harmony and good understanding between officers of the several branches of which the military establishment consists. Is it not therefore the case that instead of additional “independence” of any one portion of the army over another portion, what really is called for is greater homogeneity among all than it is to be feared exists at present. Unfortunately, one result

of the recent changes in the constitution of the Army Medical Department has been to foster a craving for “independence” which never can exist, and if it could arise, is, in the interests of the great body of the army, very undesirable.

Notes on Current Topics.

A New Surgical Dressing.

THE introduction of a new dressing material, consisting of peat-mould, is credited to Dr. Neuberg by the *Globe* newspaper. The idea is said to have been derived from a patient who came into hospital at Kiel with a double compound fracture of the forearm, and which had been temporarily treated by surrounding it with a thick paste of peat-mould, on which a rough wooden splint had been laid. Some time had elapsed between the occurrence of the accident and the patient's admission to hospital, at which time he was in good general health, while the wound was in a most promising condition and healing well. The success attending this case led Dr. Neuberg to investigate the quality of peat-mould as determining its fitness for the use to which it was put. His experiments show that the fine dust produced by the circular saw with which peat blocks are cut into shape is the most useful dressing material, and in employing it Dr. Neuberg uses two bags, one larger than the other, and both filled with the peat, the mould in the lesser bag containing $2\frac{1}{2}$ per cent. of iodoform, while that in the larger is saturated with a 5 per cent. solution of carbolic acid or other germicide. The smaller bag being on the wound, the larger is placed over it, and the whole bound in place by a gauze bandage. The advantages claimed for the method are these:—1. A given quantity of the mould takes up more fluid than jute, gauze, or cotton-wool. If it be slightly moistened its absorbent power is increased. 2. It has great power of absorbing products of decomposition of organic substances, and hence prevents these occurring. 3. The moistened mould is a very soft, but still elastic substance, and so is easily placed in the required position in the bags before applying them to the inequalities of the body. 4. It is the cheapest of known antiseptic dressings, one pennyworth being sufficient for one dressing, and still less if the preparation with an antiseptic be left out. 5. It makes a very suitable pad for all purposes when enclosed in gauze.

The Proposed Irish Academy of Medicine and Surgery.

THE movement to promote an amalgamation of all the Medical, Surgical, and Pathological Societies of Dublin into one Academy of Medicine, to which we referred three months ago, has been at a standstill during the summer recess, because of the inability of the Council of the Royal College of Surgeons to find time for discussing the proposed merging of the Surgical Society of Ireland in the Academy. The Surgical Society was originally established by the College, has been always accommodated in the collegiate buildings, and chiefly supported out of collegiate funds, and all changes in its arrangements have, therefore, the sanction of the College Council. The proposal to change the Society into a Surgical Section of the

Academy needed, therefore, to be approved first by the Council of the Society, then by the members at large, and finally by the Council of the College, and the almost unanimous assent of the Society having been obtained, the matter came before the College Council last week. It was resolved, therefore, "That the sanction of the Council be given, as requested, to the amalgamation of the Surgical Society with the proposed Academy of Medicine, on condition that, should such Academy be formed, a Surgical Section shall be maintained in the Academy, and that Surgery shall be adequately represented in the governing body of the institution; that the Council is disposed to afford to the Academy, as far as possible, such support and accommodation as has heretofore been given to the Surgical Society." The chief difficulty in the floating of the new Academy having been thus removed, a general meeting of the promoters was held on Saturday last, which was largely attended. A resolution was adopted appointing a Sub-Committee, consisting of the Presidents and Secretaries of the amalgamating Societies, together with Drs. Kidd, McDonnell, H. Kennedy, E. Hamilton, and A. H. Jacob, to finally revise the scheme of coalition and to report on Saturday, the 28th. The hope was expressed that the new Academy might be in a position to hold its first meeting within the month of November.

Another Case of Alleged Neglect at Guy's.

MR. W. J. PAYNE conducted an inquest at Guy's Hospital last week, on the body of a woman who, having sustained a Colles' fracture of both wrists, was attended to at Guy's hospital, and after the broken bones were set, was sent to her home. The next day, at her friends' request, the patient was admitted into the hospital, and some few days later amputation of one arm became necessary, soon after which death took place from exhaustion. It is not, of course, possible, in the absence of fuller details, to determine exactly the features of the case; but so far there does not appear the slightest reason why the jury should attach to their verdict of accidental death a rider declaring that the want of proper care and caution upon the part of the hospital authorities accelerated the fatal termination. We have already commented on the unfortunate alacrity exhibited by coroners' juries in placing the worst possible and most injurious construction on every occurrence that takes place at Guy's. We are glad, therefore, that the coroner promptly refused, as he has discretion to, to record more than the verdict of accidental death; especially as the rider added by the jurors was based mainly on the fact that the deceased woman had been sent away when her fractured arms had been set. As Dr. Steel, medical superintendent to the hospital insisted, the limited resources at their disposal necessitated that the medical authorities should detain only such persons as it was absolutely necessary to keep under constant supervision. The case referred to was not necessarily such a one, though we can readily imagine that it would have been kept for a time at any rate, at many similar institutions; this action would doubtless be regarded as excess of caution at Guy's, whose officers could not actually be accused of unscientific conduct when acting on their convictions to this effect.

In connection with a recent case of death occurring to a cabman soon after he was sent away from Guy's hospital on the house-surgeon's declaration that he might safely go home, and concerning which strong expressions of opinion adverse to the hospital were made by a jury, and repeated by the lay press, we are glad to know that a full inquiry has been demanded by the authorities of Guy's. We cannot too much deplore the unfortunate hostility of the public towards this ancient charity, nor, although gratified at the changed attitude of those who originated all its troubles, can we wholly forget the blame that is due to them. They cannot fail to see the consequences of their rash enthusiasm in current annoyances and the reduced popularity of the school at Guy's.

The Resignation of the Medical Officer of the Lismore Union.

WHEN the guardians of a union are encouraged by the supreme authority of the Local Government Board to get rid of a medical officer against whom no charge has ever been substantiated, we fear that there are many people who conceive, on the principle that there is "no smoke without fire," that there must be some underlying reason for such a course of conduct or some secret information before the Local Government Board to justify them in throwing their officer to the mercies of his enemies on the board of guardians. This is usually a very unjust suspicion, and, in the case of Dr. O'Reilly, lately victimised in this way, we can assert that it is entirely without foundation. When the Lismore guardians were manoeuvring to drive out Dr. O'Reilly because they did not care about him, the Catholic clergy of the locality, including the Abbot and Sub-Prior of Mount Melleray Abbey, the Lady Superioress of the Presentation Convent, the Superior of the Christian Brothers, and the Priest of the Parish, testified unanimously and warmly to Dr. O'Reilly's exemplary character, professional and moral. The committee of his dispensary, through their chairman and hon. sec., declared that Dr. O'Reilly had "performed his duties with care and zeal, and with satisfaction to the committee and benefit of the poor." This is the officer whom the Lismore guardians bullied into resigning. We are not surprised at that or any other act of petty tyranny by an Irish board of guardians, but we want to know how the Irish Local Government Board proposes to justify itself in encouraging the transaction as they did when every sense of justice and the faintest appreciation of the nature of their functions and prerogative should have induced them to protect an officer who for thirteen years had borne so high a character?

Lead Poisoning.

A GOOD deal of interest has recently been aroused by the occurrence of several cases of poisoning by lead, which at first presented many obscure features, but concerning the nature of which careful inquiry removes all possibility of doubt. Although some few of the apparently inexplicable cases of poisoning encountered may be attributable to contaminated water supply, as happened a short time back at Sheffield, yet there are unquestionably large numbers of deaths due each year to actual absorption of

lead from without during the working hours of each day. Very many of our national industries unfortunately entail on those who engage in them the dangers of plumbism in its worst forms; and we have on more than one occasion, insisted on the prime importance of placing all such manufactures under a system of supervision which shall minimise to the utmost possible extent the mischief arising out of them. A week never passes that more than a single case of death from this cause, and often under most distressing circumstances, is recorded. A good deal of the apathy with which this danger is viewed is undoubtedly due to the little interest taken in their own concerns by the ones most nearly affected, the labourers engaged in lead works. Since, however, they decline, or are careless, to help themselves, it is incumbent on others to see that they do not unduly suffer from their own supineness, and take steps for reducing, as far as possible, fatalities due to this particular form of manufacture.

The Annual Election at the Irish College of Physicians.

THE choice of the officers of the College took place on Wednesday last—St. Luke's Day—when the following officers were chosen:—*President*—William Moore, M.D. *Censors*—Francis Robert Cruise, M.D. (Vice-President); Arthur Wynne Foot, M.D.; Christopher J. Nixon, M.B.; and Fleetwood Churchill, F.K.Q.C.P. *Additional Examiners*—Drs. Churchill, Cruise, Foot, Nixon, Finny (in Medicine), Macan (in Midwifery), Purser (in Physiology), W. G. Smith (in Chemistry), and Duffey (in Materia Medica). *Examiners in Midwifery*—John Rutherford Kirkpatrick, M.B., King's Professor of Midwifery; and Stephen M. MacSwiney, M.D. *Registrar*—John William Moore, M.D. *Professor of Medical Jurisprudence*—Robert Travers, M.A., M.B. *Representative on the General Medical Council*—Aquila Smith, M.D. On the same occasion Dr. John H. Chapman, well known to our readers as the energetic Honorary Secretary and former President of the Irish Medical Association, was elected a Fellow by a majority of votes which approached unanimity.

Fees for Medical Certificates and Evidence.

IN our last issue we noticed a case which had arisen at Portsmouth, wherein the house-surgeon at the Royal Portsmouth Hospital had refused a certificate to the police, and was refused his fees when subsequently attending the police-court upon a verbal subpoena. We consider Mr. Williams was perfectly justified in his refusal, and the controversy which has since arisen in the town and the local papers fully confirms this view. The case may be thus briefly summarised:—Upon the police demanding of Mr. Williams a certificate of the condition of a woman detained under his charge (in consequence of injuries received at the hands of a man now in custody on the charge of attempting to murder her), he asked for the customary fee, which, being refused, he declined to give, maintaining that, although the medical profession is never backward in rendering a private service to a poor individual, the case is altered when professional assistance has to be given to a public department. The reports furnished to the police require skill and experience, and involve considerable responsibility, as well as the liability

to appear subsequently in the witness-box, and it is no part of the object of a hospital to furnish gratuitous medical advice to police or other authorities. Mr. Williams justifies his action by the medico-legal aphorism, that in all cases but those of coroners' inquests the medical witness, whether house-surgeon of a public hospital or not, is entitled to the usual fee, be it for attendance before a magistrate's court, the Sessions, or the Assizes; but in many cases (as in the present one) it is necessary for the medical man, in order to claim his right, to be assured, before he gives evidence, by some responsible person, that his fee will be paid. The local police have, it appears, been in the habit of summoning medical men merely by a verbal message. Hitherto it has been understood that such message should be delivered a reasonable time before the medical man's attendance at court was required, and upon that tacit understanding the medical man has undertaken, upon all such occasions, to attend to the notice as he would to a legal summons. Now this understanding has been broken by the police adopting the novel expedient of demanding gratuitous medical advice. When the prisoner was again brought up and further remanded on Saturday last, the 21st inst., Mr. Williams attended the court upon a subpoena. This, it is understood, he will do also in future cases, on the ground that a medical witness is not bound to attend as witness at a trial except on subpoena, which should be served a reasonable time before trial to enable him to put his affairs in such order that his attendance on the court may be as little detrimental as possible to his interests.

The Irish Medical Association.

THE first general meeting of the Council of the Association succeeding the recess was held at the Royal College of Surgeons in Ireland on Friday last. The Report of the Committee of Council, which we hope to print fully in our Poor-law Supplement, was presented. It was devoted chiefly to a *résumé* of the proceedings in connection with the Union Officers' Superannuation Bill, which, in the opinion of the Committee of Council, was in a very promising condition for final legislation in the next session of Parliament. The Committee also congratulated the Association on the prospect of medico-educational reform held out by the recent Report of the Royal Commission on the Medical Acts, but was of opinion that the projected Medical Acts Amendment Bill would not be satisfactory or effective unless it ensured uniformity of curriculum, standard of examination, and fee throughout the kingdom, such uniformity being the only safeguard against the underselling competition which has heretofore induced students to run from England and Ireland to Scotland to seek cheaper and easier diplomas. The Committee of Council also considered the recommendation of the Commission as to "quacks" clauses of the proposed Bill unsatisfactory, because they recognise the legality of unlicensed practice for gain.

The remainder of the Report of the Committee of Council was devoted to consideration of the scale of fees to medical witnesses recently promulgated by a committee of the Irish judges, which the Association considered little less than insulting to the profession. The pro-

ceedings of the Committee in reference to the much needed reform of the Irish muddle of vaccination were also reported, and a case was reported in which the fees due to a consultant of a board of guardians for aid afforded to a Poor-law medical officer were recovered by law by the Association on behalf of the practitioner who was entitled thereto. The Report of the Committee having been adopted, resolutions were brought forward by Dr. Bellew Kelly, of Drogheda, which declared unsatisfactory the existing system of electing Poor-law medical officers, and of holding sworn inquiries into charges made against medical officers. These subjects were remitted to the Committee of Council for their consideration.

Finally, the circumstances attending the resignation of Dr. O'Reilly of his surgeonry of the Lismore Workhouse were brought under notice, and it was ordered that a letter be addressed to the Local Government Board protesting against the course adopted by the Board in permitting Dr. O'Reilly to be sacrificed to the personal pique of a majority of the guardians, and asserting the principle that a Poor-Law medical officer shall not be deprived of his office for any other cause whatsoever than incapacity or unwillingness to perform his duty, as proved after public investigation of specific charges.

A Dentists' Bill for Australia.

A BILL for the regulation of the practice of dentistry in Victoria has been introduced into the colonial legislature. Like the British Act, it is based upon the reservation of the title of "dentist" to registered persons; but the Australian dentists have taken warning from the unhappy results of the British Dental Act, and the Bill, therefore, contains no provision for the registration of those who have *bona fide* practised it "in conjunction with the practice of medicine, surgery, and pharmacy," similar to that which was introduced into the British Act. The dental profession in Australia will, it seems, be deprived of association with the druggists' boys of the colony.

Sham Brandy.

THE *Chemist and Druggist* thus enlightens us in its last issue on the manufacture of "Rhenish Brandy" without the assistance of brandy spirit. Says our contemporary:—"It is well known that but a slight proportion of the wine sold and consumed as Bordeaux, Rhine, port, &c., is really what it pretends to be, and that a still less proportion of the brandy sold and consumed as genuine French eau-de-vie is really such. It is also equally well known that various methods are resorted to to produce liquors which are intended to resemble the true beverages as far as may be, some of which substitutes are really made from wine, and are perfectly potable and wholesome, while others are mixtures of various composition, ranging from those which are palatable and may be consumed without absolute danger to the human economy, down to those which are nauseous to the taste, and must be considered deleterious, if not worse. A German firm, calling itself "Export Compagnie für deutschen Cognac," has announced that it prepares a potable and wholesome "Rhenish brandy" from pure and genuine materials, and which it undertakes to

supply in any quantity. We have," says the Editor of the *Chemist and Druggist*, "received samples of their product, and have tested them chemically *without finding anything deleterious*. The brandy is possessed of an excellent taste and aroma, quite equal to the ordinary varieties of genuine eau-de-vie. The brandy is considerably cheaper than French brandy of equal quality."

The Belfast Guardians on Poor-law Superannuation.

THE generous gentlemen who save the pennies of the Belfast ratepayers, and who sent one of their number to London to inform the House of Commons that if a union officer was old, broken down, and poor, they would kick him out and let him starve, but on no account pension him, have been circulating amongst the boards of guardians throughout Ireland the following resolution:—

"That, in the opinion of the Belfast board of guardians, the present law vesting them with power to grant superannuation allowances to union officers who may from infirmity, incapacity, accident, or old age, be considered entitled thereto, is sufficient for all practical purposes, and has been hitherto found to work satisfactorily and well; and any legislation bearing on the subject which would be calculated to remove this power from the guardians (who are the direct representatives of the people, and who have personal knowledge of all the circumstances of the respective cases), and vest it in the Local Government Board exclusively, would be fraught with universal disadvantage and dissatisfaction to the Poor-law ratepayers of this union, and that a copy of the foregoing resolution be forwarded to all unions in Ireland, requesting co-operation."

As the only "practical purposes" which the Belfast guardians care about is the getting of the ultimate atom of work out of an officer for the very minutest possible pay, we are not surprised to hear that they consider the law which has starved several Poor-law doctors to death has worked "satisfactorily and well." It is, however, we think, nothing less than disgraceful to the Belfast guardians that they should seek to stir up opposition to the Superannuation Bill by means of a misrepresentation which may be deliberate or may be the result of culpable ignorance. If these guardians could bring themselves to expend 1s. 3d. of the rates on a copy of the Select Committee's report on the subject, they would learn that no one now proposes to "remove the pensioning power from the boards of guardians and vest it in the Local Government Board." On the contrary, the Bill, as recommended to the House of Commons, proposes to confide the consideration of all superannuation claims, in the first instance, to the boards of guardians; but it will, let us hope, put an effective check upon the contemptible meanness of boards constituted as is the Belfast board.

Compulsory Notification at Liverpool.

WE learn with much satisfaction that the effort to impose upon the profession the duty of notifying infectious disease to the sanitary authority was totally defeated last week, and the attempt may be looked upon as shelved, as far as Liverpool is concerned, for some time to come. The chairman of the Health Committee of the Town Council had, it seems, determined to carry dual notification whether the doctors liked it or not, and in his own committee he carried with difficulty a recommendation to

that effect by his own casting vote. This recommendation being brought to the Town Council for confirmation, was hotly contested by Dr. Hamilton and Dr. Marsh, members of the Council, and after a vigorous battle, its adoption was adjourned until the Greek Kalends.

The profession of Liverpool have their own energy, and especially that of their leaders, Dr. Carter, Dr. Hamilton, and Dr. Ewing Whittle, to thank for this victory, which ought to encourage all medical men threatened with the notification infliction to resist actively. They may be assured that, in doing so, they are fighting the battle of the public against sanitarian hobby-riders, and that if they succeed in defeating this notification crusade against the physician they will be doing good work for the community at large.

Soothing Syrups.

THE following editorial remarks upon the sale of patent medicines containing poisons appeared in the *Globe* of the 17th inst:—"The vices and virtues of soothing syrup as administered to infants were again discussed at an inquest held upon the body of a child which had been only too effectually soothed by a dose of it. This medicine, if it should so be called, is sold under a Government stamp, and is therefore naturally regarded by many persons who use it as having a sort of official certificate of harmlessness. Dr. Diplock, who has had some experience before of the fatal results produced by these syrups, explained that some of them contained ingredients which may be harmless to one child, but 'most fatal' to another; and the medical man who had conducted the post-mortem examination averred that the bottle out of which the dose was taken contained enough poison to destroy half-a-dozen children. The revenue is, of course, benefited by allowing such mixtures to be stamped and sold, and would suffer considerably if the stamp were refused to all medicines containing any poison. But the public will very generally agree with the coroner's jury in thinking that 'some restriction should be placed on the sale of medicines which can be used as poisons.' It is often difficult to ascertain whether an overdose has been given or not; but in the case investigated it seems that even an ordinary dose may have caused death."

The Medical Society of London.

At the opening meeting of the Medical Society of London, last week, the President, Mr. Francis Mason, in a few introductory remarks, made special reference to the extensive alterations that were being carried on in the Society's premises. The Fellows would remember that when he had the honour of taking the chair as President for the first time in March last, he hinted that the Council were contemplating taking additional premises, in order to provide increased accommodation for the library, as well as to add to the comfort and convenience of the Fellows. He was now happy to say that that project had been realised, and he believed that after the completion of the work the Society's rooms would be second to none in the metropolis. A lease had been secured for about 63 years at what was considered a fair rental; but the acquisition of

the new premises and their alteration and improvement involved a considerable outlay of money; but they were not without friends, for a most respected past president had lent them a sum of money to tide over temporary difficulties, and much consideration had been shown by the present tenants of the Society, who fully recognised the advantages that were likely to follow a temporary inconvenience. The President asked for the kind indulgence of the Fellows themselves, and assured them that during the alterations no effort should be spared to render the Society's rooms as comfortable as the circumstances would permit. After passing a well-merited tribute to the two hon. secs., Mr. Edmund Owen and Dr. Isambard Owen, for their unflagging zeal and interest in the Society the President concluded by asking the Fellows to commend the Society to the notice of their friends as one well worthy of support and encouragement on account of its historical antiquity, the character of its library, and the unquestionable vitality it possessed in diffusing to an unlimited extent increased knowledge of medicine, surgery, and the allied sciences.

The Native Guano Company.

On Thursday last a large number of scientific and literary gentlemen proceeded by special train from Paddington to Aylesbury, at the invitation of the chairman of the Native Guano Company. The object of the excursion was to witness the A B C process of converting sewage into manure, and also an exhibition of fruit and vegetables grown with the manure. The show was very successful, and fully demonstrated the value of the native guano for farming and gardening purposes. At the luncheon which followed, speeches were made by the Lord Mayor of London, the Hon. W. Massey Mainwaring (chairman), Mr. Sillar, and others.

Optimist Views of the Future of the Profession.

THE *Students' Journal*, referring to the address delivered at the recent annual meeting of the members of the North of Ireland Branch of the British Medical Association, by Dr. E. Thompson, of Omagh, remarks that he took a very hopeful view of the future of the profession, and expressed the opinion "that a day of social advancement is so quickly approaching for our profession, and it is so rapidly improving both in the tone and spirit of its members, that the time is not far distant when all medical men will understand in a truly practical manner the duty of being true to their profession and to each other."

The *Students' Journal* does not share this optimist view—indeed, cannot but think that he knows very little indeed about the present state of practitioners, or he would scarcely write so cheerfully on the subject:—

"During the past ten years we have watched the medical practice in London very closely, and we can truly say that, as regards general practice, it has been going from bad to worse, and from worse to still lower depths up to the present time. At no time has the outlook been worse than it is just now. Every department of practice is overcrowded, and a large proportion of practitioners have no notion whatever of professional honour and dignity. They act as if they were engaged in a trade, and do not care how small a fee they accept. There is scarcely a district in the metropolis but swarms with so-called 'dispensaries'

and open surgeries, where advice and medicine can be obtained for a shilling, and in the poor neighbourhoods qualified surgeons are content with a fee of sixpence, whilst some are even content with fourpence for each attendance, and we have known a qualified doctor advertise to give *advice and medicine for twopence!* And it is of no use to complain of those who so degrade the profession; their answer is that they must accept low fees or starve."

THE typhoid fever epidemic in Paris is increasing with alarming rapidity, 250 deaths having occurred there last week from this cause, against 134 of the previous week.

DR DAVAINX, the discoverer of the baccillus of charbon, has just died in France. His most important work, to which the Academy prize was awarded, is, "A Memoir on the Contagion of Charbon in Animals."

THE scarlet-fever epidemic at Accrington continues to be so alarming, and to spread so widely, that the Health Committee have decided that the schools must again be closed. It was stated at a meeting of the Health Committee, on the 18th inst., that since the commencement of the epidemic more than five hundred cases of scarlet fever had been reported, and the fatal cases had numbered between ninety and one hundred.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Plymouth 12; Brighton 14; Edinburgh, Wolverhampton, Bradford, Norwich 15; Bristol, Leicester 16; Nottingham 17; Birkenhead 18; Portsmouth, Birmingham, Halifax, Hull, London 20; Salford, Huddersfield, Sheffield 21; Derby 22; Blackburn, Glasgow 23; Dublin, Bolton 24; Manchester, Cardiff, Preston 25; Newcastle-on-Tyne 26; Leeds 27; Liverpool, Sunderland 28; Oldham 34.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 25, Bombay 23, Madras 39; Paris 27; Geneva 24; Brussels 19; Amsterdam 21; Rotterdam 18; The Hague 19; Stockholm 26; Christiania 17; St. Petersburg 39; Berlin 26; Hamburg 18; Dresden 21, Breslau 29, Munich 26, Vienna 22, Prague 26, Buda-Pesth 23, Trieste 19; Rome 21; Venice 22; New York 27, Brooklyn 23, Philadelphia 20, and Baltimore 29.

THE annual death-rates per 1,000 in the large towns last week, from diseases of the zymotic class, were:—From scarlet fever, 1.3 in Leeds, 1.4 in Sheffield, and 2.1 in Leicester; from measles, 1.8 in Cardiff and 6.6 in Sunderland; from whooping-cough, 1.2 both in Cardiff and Birkenhead, 1.5 in Blackburn; and from "fever," 1.7 in Leeds, 1.8 in Birkenhead, and 4.4 in Portsmouth. The 45 deaths from diphtheria included no fewer than 26 in London and 11 in Glasgow. Small-pox caused 4 deaths in London, 2 in Newcastle-upon-Tyne, and one in Manchester.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

EDINBURGH ROYAL INFIRMARY.—At a meeting of the managers of this institution, held on the 16th inst., Dr. Byrom Bramwell was unanimously appointed Pathologist to the Infirmary in room of Dr J. D. Hamilton, now Professor of Pathology in Aberdeen University. Dr. MacGillivray, who has been acting as house-surgeon, was appointed assistant-surgeon to the hospital in room of Mr. Chiene, now Professor of Surgery.

GASTRIC FEVER IN BONHILL PARISH.—Gastric fever of a bad type prevails greatly in certain portions of this parish at present. In Bonhill village a few cases are reported, while in same town quite a number are known. In all, there are thirty cases. One death occurred on the 14th inst., and other patients are in a critical state at present. Bad water and contaminated milk are suspected as the cause, while the late close, wet weather has assisted to propagate the disease.

GLASGOW DEATH-RATE.—For the week ending with Saturday, the 14th inst., the Glasgow death-rate was 23 per 1,000 per annum. For the corresponding weeks in 1881, 1880, and 1879 the figures were 23, 24, and 18 respectively.

ABERDEEN UNIVERSITY STUDENTS.—The directors of the Aberdeen Music Hall Company have declined to let the Music Hall Buildings on the occasion of the delivery of the rectorial address by Dr. Alexander Bain to the students of the University. The directors complain that on a former occasion the building was much damaged in consequence of the disturbances that invariably took place on such occasions, and in particular the gentlemanly sport of throwing peameal.

MUNIFICENT GIFTS TO ABERDEEN CHARITIES.—Mr. Thompson, of Pitmedden, has sent the following sums to the treasurers of the undernamed charitable institutions in Aberdeen:—Royal Infirmary of Aberdeen, £1,000; Royal Lunatic Asylum, £500; Convalescent Hospital, £300; Incurables' Institution, £200; General Dispensary, £200; Deaf and Dumb Institution, £200; Oldmill Reformatory, £200; Sick Children's Hospital, £200; besides various sums to non-medical institutions.

SUPERINTENDENT OF STATISTICS FOR SCOTLAND.—We have reason to believe that Dr. Robert James Blair Cunynghame has been selected as Superintendent of Statistics in the Registrar-General's office, vice Dr. Robertson, deceased.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 14th inst., the mortality of Edinburgh was only 62, and the death-rate 14 per 1,000. The zymotic mortality consisted of 8 deaths, of which 6 were due to scarlatina. The intimations of this disease were 66, as compared with 99 in the previous week.

A PHYSIOLOGICAL CURIOSITY.—According to the *Scotsman*—an authority which in non-political matters is not to be questioned—there is being exhibited at present in one of the stalls of the Edinburgh Waverly Market, a Zulu boy whose body is so charged with electricity that, on touching him, what is understood to be an electric shock is experienced. He is about six and a-half years old, speaks English, and is a bright, happy, and characterist-looking little fellow. Kinkon's somewhat odd characteristic, which is stated to have distinguished him from infancy, is said to vary con-

siderably with the state of the atmosphere; but the act of shaking hands with him would seem to be generally attended with a quivering sensation like that produced by an electric current in the wrist and arm, while contact with his tongue gives a smarter shock.

HORSE-HAIR EELS.—Can any of our readers throw light on this interesting question? In Scotland, at least, the belief is a prevalent one that horse-hair plucked from the tail and mane, immersed in water, during the heat of summer, assumes the form of small living eels. Speaking from boyish experience, however much we may lay ourselves open to the charge of undue credulity, we are of those who believe they have seen this phenomenon. We do not venture on an explanation. The following contributions to the subject appeared last week in a widely-circulated Scotch newspaper. An Edinburgh correspondent writes:—"Kindly allow me space for a few words in corroboration of J. M'Donald's letter in your issue of 30th September regarding the 'Horse-hair Eel' question. I have frequently for amusement, when living in the country, put horse-hairs taken from the mane or tail into water, and always found that they came to life in from fourteen to twenty-one days, according to the heat of the weather. I will now describe the process as I witnessed it, having watched them daily. After being in the water for a few days, a white slimy matter began to cover the head, or thick end of the hair, which gradually extended downwards. After it had reached about the middle of the hair the head began to assume a darkish colour, while two small eyes became visible, and the head began to move backwards and forwards. In a few days more the white matter reached to the end of the hair, and in a day or two afterwards it had all assumed a dark colour, when it could be seen moving freely about in the water." "D. F., Inverness, also believes that horses' hair turns into eels. He says:—"I have often tried the experiment, and found it to be a complete success. I have tried it in ponds, and had I not gone further than that I might have had suspicion that the living animals (or insects) I observed a few days after I had cast in the horse's hair might be the insects referred to by your correspondent as the horse-hair worm. But to satisfy my curiosity I tried the experiment in a cask of water, where I was sure there were no other insects, and I watched them daily and saw for myself that every one of the horse's hairs I had cast in assumed life and made rapid progress in growth, and they swam about in the water like ordinary eels."

THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At the last meeting of the College, Professor Turner was elected President. The examiners, as is the custom of the College, unanimously re-elected themselves for the ensuing year.

PRACTICAL PHARMACY IN EDINBURGH.—As we have before stated, there is an attempt on the part of the Professors of *Materia Medica* to impose a so-called practical *materia medica* class on the already over-burdened student. The teaching in this class is, we understand, much as follows: The *Pharmacopœia* is taken as a text-book, and the student is informed of the names of the drugs, their habitat, and the preparations into which they enter; all of which he should be taught in the ordinary systematic course of lectures. These are, however, devoted, we understand, to the physiological and therapeutical action of drugs, which are so minutely dwelt upon that a student not long ago gravely proposed to inject a solution of pilocarpin into a baby six days old suffering from the not unusual jaundice which attacks infants a few days after birth. Having thus laid so valuable a basis of physiological and therapeutical knowledge, the student is

taught in the practical class to make a powder, perhaps a mixture, and to go through a supposed qualitative analysis of drugs, and then to emerge competent to take an assistantship in England and dispense medicines. Against this arrangement the dispensaries are of course indignant, for they have really for years taught the only practical pharmacy worth knowing. We have authority for stating that the University practical *materia medica* class is not accepted in lieu of the dispensary class for the double qualification of Edinburgh.

Literature.

THE USELESSNESS OF VIVISECTION UPON ANIMALS AS A METHOD OF SCIENTIFIC RESEARCH. (a)

AN attentive perusal of this *brochure* caused us to regard it rather in the light of one of those effusions which team from the social science pen; and we were rather inclined to regard the fixture of Mr. Lawson Tait's name to it as an elaborate but clumsy practical joke on the eminent surgeon on the part of some professional wag in Birmingham. We learn, however, that it is an authentic document, and are therefore obliged to notice some of its principal errors and omissions—to fully notice them all would be entirely beyond the space at our disposal.

In pages 124-5 the author speaks of the "alleged discovery of the circulation of the blood by Harvey," adding that "it is only our insular pride which has claimed for him the merit of the discovery." This amazes us; for we had always been under the impression that, although the *pulmonary* circulation was known previous to his time, Harvey was the discoverer of the systemic circulation, including even that of the capillaries. The chorus of incredulity with which the "exercitatio anatomica" was received by the Lawson Taits of the seventeenth century, home and Continental, would be sufficient evidence of this fact; to which it may be added that, although Harvey died at an advanced age, he can hardly be said to have lived to see his immortal discovery *universally* acknowledged. We were present at the great International gathering at Folkestone last year, and certainly their verdict was not that of our author. That Harvey owed no share of the discovery to experiments on living animals is certainly not a fact. A new department of scientific medicine—the therapeutical action of medicines—is now being erected, and is based largely upon experiments on living animals. Of this the author thus briefly disposes (p. 127):—"On the question of new drugs I can speak only with great reserve, for such a wholesome scepticism concerning drugs has been introduced by the medical schism of homœopathy, that I look upon all new drugs with suspicion." Further on: "I fear most new drugs do more harm than good; some of them, such as chloral, have certainly done so." All drugs, including chloral, can be abused; but does the author forget that tartar emetic, iodine, bark, quinine, and morphia were new and unknown drugs until within the memory of many living persons?

The author gives a long list (in most of which we cannot agree) of alleged inconclusive experiments upon animals with a view to medical and surgical research, and appears to be under the idea that such experiments should be confined to human subjects. We take issue with him on this point, and maintain that any such experiment performed with honest intention upon an animal is justifiable; and that, even if it prove inconclusive, it at least tends and contributes to justify the human experiment. With regard to transfusion of blood from one subject to another, the author's brief verdict is, "Personally, I have no confidence in the proceeding." Can this be merely ignorance?

We could multiply such quotations *usque ad nauseam*, but it is unnecessary. We will merely express our surprise that the author is silent upon the triumphs of vivisection in physiology. Nothing is said of the unravelling of nervous secrets by Sir Charles Bell, or the experiments of Majendie,

(a) "The Uselessness of Vivisection upon Animals as a Method of Scientific Research." By Lawson Tait, F.R.C.S., &c. Read before the Birmingham Philosophical Society, April 20, 1882, and reprinted by permission from the Society's Transactions. Birmingham, 1882.

Brown-Séquard, or Claude Bernard, which have established facts now the alphabet of the profession, and which could have been found out no other way—among them almost the only fact we know as to a producing cause of the important disease, diabetes. Koch's researches on the production of splenic fever or pyæmic poisoning are not alluded to; nor is his latest and greatest discovery of the phthical bacilli. From phthical sputa he cultivates in proper fluids successive generations of bacilli. A guinea-pig is inoculated with the bacillus and tuberculosis produced in the animal. We learn from current numbers of the journals that microscopic examination of the coloured bacilli is being used as a crucial clinical test in the diagnosis of the existence of consumption in human patients; and exact directions are given how to work the test, which we intend without delay to employ. Nay, more, the research gives some indications of a remote possibility of a phthical preventive, analogous to vaccinia, being discovered. Yet, according to our author, the lives of a few rabbits and guinea-pigs are too valuable to justify this human benefit. Either the author does not know all these facts, or knowing, does not mention them. A few days ago the *Times* recorded a pigeon-match between two noble swells as to who would kill in a limited time the larger number of 100 pigeons each. The winner conquered by four birds, and in the match over 180 of these hapless creatures died, very many in great agony. What would our author think of a crusade against this (to coin a new word) "vivifusillation!" We will gladly join him.

The paper was read by this eminent surgeon before a lay audience, and he himself (p. 131) notices and endeavours to explain the act on the *tu quoque* principle. We were present at the discussion on vivisection at the International Medical Congress last August. One member of the Congress (of course, a medical man) spoke against vivisection. He was most courteously listened to, got every latitude, was courteously argued with, and his remarks were accurately reported in the "Transactions." Would not that have been a more suitable theatre for Mr. Lawson Tait than the Birmingham Philosophical Society? It would have had, however, the disadvantage that his case would have been at once disposed of, and all his sophistries exposed, and that much more effectually than it is on the present occasion. Q.

DR. RALFE ON MORBID URINES. (a)

THERE can be no doubt that Dr. Ralfe's energetic protest against the neglect with which, during the last twenty years, physicians have treated urinary derangements resulting from chemical changes occurring within the body, is fully merited; and equally certain is it that he has conferred an inestimable boon on practitioners by the publication in a convenient and practical shape of the results derived from his own observations in this branch of scientific medicine. An accomplished chemist, he is peculiarly fitted to approach such a task as has been successfully accomplished in the little manual before us; its arrangement is so clear, concise, and comprehensible, and it is so replete with suggestions in respect to treatment, that it must prove a valuable assistant in many instances where, without the aid it affords, practitioners would be almost hopelessly puzzled "what to do next."

The book opens with a chapter on the "Formation and Removal of Acid from the Body," a chapter which is pregnant with suggestion, and which must necessarily excite regretful feelings in the mind of the reader when he reflects on the little importance he has been accustomed to attach to conditions whose first insignificance is not their least importance. The second and third chapters are devoted to dyspepsia, associated with an acid and with an alkaline condition of urine respectively. "For cases of flatulence and acidity," Dr. Ralfe writes, "I have found considerable benefit result from the use of turpentine in from ten to fifteen drop doses, taken shortly after food. By acting as a stimulant to the mucous membrane of the stomach and intestines, it increases the quantity and improves the quality of the secretion, and diminishes the catarrh of those organs. It checks the formation of sarcoma. In the majority of cases it has a laxative effect, and thus relieves constipation without recourse being had to other remedies. The best

mode of administering it is as follows:—Ten drops of spirits of turpentine are suspended in four drachms of acacia mixture; to this is added a drachm of glycerine, containing five drops of pure chloroform in solution, twenty grains of bicarbonate of soda, and cinnamon water to one ounce." For the relief of acidity he urges the administration of alkaline bicarbonates two or three hours after meals; and in place of purgative medicines, which must be avoided as much as possible, warm solutions of Carlsbad salt, &c., are recommended.

Chapter IV., on "Derangements Associated with Deposits of Uric Acid," contains a valuable summary of the pathological and clinical conditions under which the acid and its salts are deposited, and a criticism of the theories descriptive of the rôle played by uric acid is added. Dr. Ralfe dissents from the conclusion that an increased formation of uric acid results from liver derangements induced by excessive alcoholism, and adduces the fact that gouty subjects are not spirit drinkers. He ascribes the principal agency to wines containing the greater amount of saccharine matters, free acids, and salts, such as port, sherry, and burgundy. The frequency with which gout develops in drinkers of sugary beverages, such as London porter and heavy beers, is another proof to the same effect, while the comparative freedom from sugar and acids of spirits tends to a similar conclusion. Due importance is attached to the recognition gradually becoming general of a direct relation between the first steps in the production of gout and a chemical alteration in the quality of the blood, chiefly in the direction of diminished alkalinity; and that we may anticipate the impetus this has given to research and speculation will bear a rich harvest of fruit, Dr. Ralfe's work itself conclusively suggests. Under the head of "Treatment of Gouty Patients," many valuable hints are given respecting both diet and drugs, the careful employment of opium being insisted on.

The derangements attended with the presence of oxalic and phosphoric acids form the subjects of the concluding chapters, an appendix being added descriptive of the effect of bicarbonate of potash on the acidity of urine. In this numerous observations made to test the influence of the salt are described in detail, the result of all tending "to establish the fact that the administration of an alkaline bicarbonate on an empty stomach increases the acidity of the system, whilst its administration after a meal diminishes it."

We would strongly recommend every general practitioner to study Dr. Ralfe's work with the care and attention it so fully deserves; none can fail to profit by it; many will obtain from it an amount of practical information they will probably be surprised to find they have so long been content to do without.

LEPROSY IN BRITISH GUIANA. (a)

THIS is an extremely handsome book, the coloured plates with which it is illustrated of a more than usually elaborate and ornamental style. In the work itself the author gives a history of the three forms or varieties in which leprosy has been long recognised, namely, the tubercular, the anæsthetic, and the "mixed." He considers that the introduction of the malady into Guiana was due to the slaves from Africa. He is unable, however, to assign a date, except that in 1796 the presence of yaws and leucoderma in that colony was mentioned. With regard to the etiology of the affection, he cites (p. 140) several opinions, each of which differs from the rest. Thus, "it is hereditary, but not specific;" it is "not specific and not hereditary;" it is "specific, miasmatic, and not hereditary;" it is "specific, contagious, and hereditary." Adverting to the "parasitic theory," Mr. Hillis (p. 142) quotes the views of Hansen, Carter, Thinn, and Neisser in reference to the existence or otherwise of a specific bacillus; but adding his own opinion (p. 146) that "leprosy is essentially a contagious disease, and that it is propagated by means of its specific products," but without saying in what those "specific products" consist. That the affection is described as contagious appears to be the result of experiments in inoculating leprosy matter in animals. From these experiments, however, it appears that, whilst in man leprosy becomes a constitutional disease, in animals only a local leprosy was

(a) "On the Morbid Conditions of the Urine, dependent upon Derangements of the Digestion." By Charles Henry Ralfe, M.A., M.D. Cantab. London: J. and A. Churchill.

(a) "Leprosy in British Guiana." By John D. Hillis, F.R.C.S. M.B.I.A. London: J. and A. Churchill. 1881.

produced. As to climate, soil, race, and malaria, Mr. Hillis (p. 146) considers that little value can be attached to either in the causation of the disease. He does not attach much importance to diet (p. 148). He thinks (p. 150) that the theory of fish-eating as a cause "may be laid aside as obsolete;" that unfavourable hygienic conditions, although having a most important influence on the disease, once it is developed, "may also be eliminated from among the probable causes of leprosy" (p. 153). Opinions are quoted (pp. 154-6) in favour and adverse to a connection existing between syphilis and leprosy, and as to whether the latter does or does not originate spontaneously. Unfortunately, however, to neither is a reply given. After all that has been said, and notwithstanding the very beautiful illustrations already alluded to, what is the real and practical result obtained? It is thus described in the opening sentence of the chapter on treatment (p. 208): "The treatment of leprosy has hitherto been attended with such very poor results that the disease is now regarded as incurable." And that is all.

PROFESSOR TYNDALL'S ESSAYS. (a)

PROFESSOR TYNDALL'S many experiments on the nature of putrefactive changes have tended very considerably to help forward the progress of investigation in this and other countries, and have materially contributed towards the attainment of that knowledge on which the practical details of modern surgery are mainly based. In this volume of essays we have presented, in a form adapted to be understood by the general reader, descriptions of the experiments with which Professor Tyndall's name is inseparably associated, while the actual accounts are prefaced by a general dissertation on dust and disease. The researches of Pasteur in connection with parasitic disease of silk worms, the origin and propagation of contagious matter, the surgical application of the germ theory, and the results of examining air with the assistance of luminous beams are discussed in this section; and the concluding essays deal with fermentation in its bearings on medicine and surgery, and spontaneous generation.

It is of course with regard to the generation of contagia that this volume possesses its highest interest, and especially in that aspect of it involving a consideration of the mode of origin of the organisms found in putrefying solutions. Professor Tyndall's experiments are conclusive in refutation of the theory of spontaneity, and though he devotes considerable space to a defence of his deduction, describing the experiments from which they are drawn in ample detail, yet it is impossible to regard any part as superfluous.

The enthusiasm with which Professor Bastian has pursued his observations, and insisted on the proofs they yield of spontaneous generation, finds an echo in the earnest reasoning of Professor Tyndall, from whom, moreover, it would be difficult to dissent if the reality of his results is admitted. To whatever development this controversy as to the origin of germinal material is destined to proceed in the future, it is sufficiently certain that in the present the might of conviction is towards that side which insists on the truth of *omne vivum ex vivo*.

Professor Tyndall's writings always possess a charm for cultivated minds, in whatever shape they may be presented for perusal. These latter essays share this peculiarity in a pre-eminent degree, and will command the willing attention of every reader. The practitioner will find in them an invaluable fund of information and suggestion; and we would earnestly recommend all who share the interest with which recent discoveries in connection with infective diseases are surrounded, to avail themselves of Professor Tyndall's delightful introduction to the study of atmospheric particles and their influence in forwarding the multiple changes that form so serious an obstacle in surgical practice.

PROFESSOR HUXLEY'S SCIENCE AND CULTURE. (b)

We are so accustomed to look for occasional volumes of essays from the pen of Prof. Huxley that the reading scientific world would experience huge disappointment were they

(a) "Essays on the Floating Matter of the Air in Relation to Putrefaction and Infection." By John Tyndall, F.R.S. Longman, Green, & Co., London.

(b) "Science and Culture," and other Essays. By Thomas Henry Huxley, LL.D., F.R.S. London: Macmillan and Co.

not forthcoming at intervals. Through them, more than through any similar channel, has the study of science been popularised in this country, it being their author's proud distinction to rank second to no authority in the power of so presenting abstruse scientific problems as to make them not only comprehensible, but acceptable also, to the general reader.

The first essay in this collection, after the title of which the work is called, consists of the address delivered by Prof. Huxley on the occasion of opening the Josiah Mason Science College at Birmingham. It is throughout a defence of "Culture" as properly understood, and a denunciation of the narrow, prejudiced "practicality" of rule of thumb educators. It contains, moreover, the famous paragraph which has probably proved as troublesome an utterance to its author as the equally well-known reference years before to the corn which dies and lives again. We speak to the passage in which Prof. Huxley expressed the opinion that "for those who mean to make science their serious occupation; or who intend to follow the profession of medicine; or who have to enter early upon the business of life, classical education is a mistake," and he further went on for this reason to rejoice in the fact that "mere literary education" in the words of its founder was shut out from the curriculum of the College. The admirable exposition which was then given of Prof. Huxley's ideal of a genuine literary-scientific education, on which he warmly insists as being necessary to produce a cultivated scientific student, deserves to be read and attentively considered by every would-be educational theorist, medical as well as other. It is chiefly because Mr. Huxley has been persistently misrepresented that he is so often misquoted, for none more than he, who is himself a scientist of the highest intellectual culture, can more exactly appreciate the importance of a liberal education as an adjuvant to successful scientific labours.

With the first address in the book in the order of printing should be read the fifth, on Joseph Priestly, delivered at the unveiling of a statue of the great chemist in 1874, and the second, on Universities, actual and ideal, a rectorial oration before the University of Aberdeen in the same year. These offer an example of the telling style which Prof. Huxley adopts in his happiest flights, and serve also to lend an insight into the views which govern his thoughts on education and mental training. The majority of the remaining essays are on subjects of special scientific interest, such as "The Border Territory between the Animal and Vegetable Kingdoms," "Sensation and the Unity of Structure of the Sensiferous Organs," "Evolution in Biology," &c., &c. One of them "On Certain Errors respecting the Structure of the Heart attributed to Aristotle," is a learned and luminous defence of the ancient naturalist against the attacks made on his powers of observation; while repudiating the late J. H. Lewes' sweeping assertions, however, Mr. Huxley is careful to avoid unhesitating acceptance of Cuvier's "Exaggerated Panegyric," and offers a complete and judicial analysis of the achievements of the author he is dealing with.

The connection of the Biological Sciences with Medicine will possibly be read with more enjoyment and interest by professional students of the work, but it would be invidious to select any particular address as possessing merits not common to all. Mr. Huxley's work at all times commands attention from all men who are not wholly ignorant of the great labours he has prosecuted as a teacher of scientific truths to the masses. In these essays we have the well-considered opinions of a powerful thinker, and a prime agent in the intellectual progress of our time; for this reason, as much as for their intrinsic excellence, they are of enduring worth and priceless value.

PROFESSOR FLOWER ON FASHION IN DEFORMITY. (a)

THE object of Professor Flower's little volume is to expose the follies and dangers attendant on conformity with the exigencies of fashion respecting dress and appearance. Intended more especially as a means of instructing unprofessional readers, it is nevertheless a useful guide to medical men, who will derive many valuable hints from its perusal. Assuming that "the propensity to deform, or alter from the

(a) "Fashion in Deformity." By William Henry Flower, F.R.S., &c. Nature Series. London: Macmillan and Co.

natural form some parts of the body, is one which is common to human nature in every aspect in which we are familiar with it—the most primitive and barbarous, and the most civilised and refined,” Professor Flower first dwells on the modifications of form impressed by man on the lower animals for whatever purpose, and from this subject he proceeds to consider human deformities, classifying them according to the parts of the body affected. The work is embellished with a number of illustrations of the structural disfigurements referred to, and in its later portions deals particularly with the extravagances of modern fashion, which are productive of such intolerable mischief and suffering among women principally, but also among men as well. The slender waist and the small contracted and distorted foot are described and pictured, while the evils to which they give rise are faithfully and cogently urged in a way that must carry conviction to all but heedless followers of “fashion’s” commands. Such works as this are really wanted in our age, and we could desire to see Professor Flower’s admirable little volume published at a price and in a form which would ensure its being universally perused. Its precepts are sadly needed, as much among the less educated classes as among those whose habits and proceedings in relation to dress and appearance they are constantly striving to imitate.

LAWS RELATING TO MEDICAL MEN. (a)

ACCORDING to Blackstone, every man ought to know something of law, and the education of no one was held to be complete by the same authority unless he possessed such knowledge. Mr. Greenwood, in his very interesting work on “The Laws relating to Medical Men,” has supplied in a most ample manner a want long felt by the medical profession, no member of which can now excuse himself on the ground of the absence of correct information on the subject in a convenient form.

The first chapter gives a brief account of the early attempts at the regulation of the practice of surgery and medicine by practitioners of the healing art, so that the “King’s liege people” may “discern the learned from the unlearned,” together with the provisions made for the examination and approval of candidates by the Bishop of London or the Dean of St. Paul’s. The history of the rise of the College of Physicians under the fostering care of Thomas Linacre and the great Cardinal Wolsey is also given. In later times we come to the passing of the Medical Act of 1858, and the subsequent enactments made for the purpose of regulating medical practice and improving the status of medical men.

We have next the laws relating to registration; then those relating to physicians, surgeons, apothecaries, and dentists; then the Universities come in for their share of attention; and last, but by no means the least important part of the book, are chapters 9, 10, and 11, which deal with the law relating to medical witnesses, the law relating to malpractice, and the law affecting lunacy practice.

The weakest part of this useful volume is that which deals with the subject last mentioned; and here we look in vain for guidance as to the receiving of lunatic patients by medical men, the civil rights of lunatics, the procedure necessary to obtain a licence for a private asylum, &c., all of which might have been given in a few lines. With the rectification of this omission in a future edition, and the correction of a few verbal statements, this book will be invaluable, and should not only find a place on the shelves of the library of every medical man, but should also be carefully studied by him.

PROFESSOR MORCELLI ON SUICIDE. (b)

THE author of this book, which is an abridged edition of his larger treatise, originally published in Italy, is Professor of Psychological Medicine in the Royal University of Turin, and Physician-in-Chief to the Royal Asylum for the Insane. As

(a) “Laws relating to Medical Men.” By James Greenwood, Barrister-at-Law. With a Chapter on the “Law relating to Lunacy Practice.” By L. S. Forbes Winslow, M.B., D.C.L. Oxon., &c. London: Baillière, Tindall, & Cox.

(b) “Suicide: an Essay on Comparative Moral Statistics.” By Henry Morcelli, M.D. International Scientific Series. London: Kegan Paul and Co.

an accomplished observer he is without a rival; as a theorist he shows himself an able student of sociological problems and an earnest follower of the great masters of modern thought and of the school of Evolution.

The work consists of an introduction and two parts—I. Analysis; II. Synthesis. Under “analysis,” Dr. Morcelli discusses the increase and regularity of suicide in civilised countries, and the various influences which seem to affect its commission. To the reader who enters, with this book in hand, for the first time on a study of the subject, it will probably be a surprise to learn the almost absolute perfection to which so complicated a subject can be brought; equally astonished also will he be to discover that facts indubitably show that “in the aggregate of the civilised states of Europe and America, the frequency of suicide shows a growing and uniform increase, so that, generally, voluntary death since the beginning of the century has increased and goes on increasing more rapidly than the geometrical augmentation of the population and of the general mortality.” Statistics naturally form the basis of this conclusion, and it is to a consideration of the causes, natural, social, and individual, which influence such increase that the principal part of Dr. Morcelli’s book is devoted.

We cannot help expressing admiration at the admirable manner in which this task has been fulfilled. The pages breathe forth the spirit of research, and reflect the scientific observer in every line we read, even the lengthy and numerous tables being so compiled as to offer every inducement to the student to peruse their veriest details. Much curious information is likewise afforded as to the conditions on which exceptional death-rates from suicide are dependent; an exhaustive criticism of which is, however, impossible in this place. Of the laborious nature of the task accomplished, in this connection we can form some idea from the information contained in an appendix, descriptive of the method by which statistical data of suicides are obtained.

Part II., dealing with the synthetical aspect of the problem, considers the laws of evolution in civilised society, and develops the conclusions that suicide is the effect of the struggle for life and human selection, and that the formation of character is the cure of suicide. It is easy to discover from these chapters how deep a hold scientific evolution has taken on the mind of our author; and it is highly instructive also to observe the vast assistance he has derived from these principles in formulating the conclusions to which his investigations have directed him.

Judged by its intrinsic importance, this volume of the International Scientific Series ranks among the best of these well-known manuals. To the psychologist and the physician it will be a fascinating study, while the information it affords is indescribably valuable to every student of social problems.

Correspondence.

THE RISKS OF HEROIC DOSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On reading your comments (Oct. 11th) on the unfortunate occurrence at Colombo, where an overdose of *Felicitas Maris* administered for tape-worm caused the death of the patient, I was reminded of a somewhat similar accident that befel an able and conscientious medical officer some years ago in India. Captain D., who had been in the habit of taking morphia occasionally for some neuralgic pain, wrote one night about 11 o’clock to the civil surgeon and begged him, as he was suffering excessive agony, to send at once two grains of morphia. Captain D. took what was brought back, and on the following morning was found dead in his bed.

At the inquest the civil surgeon stated that, considering two grains of morphia an unnecessarily large dose, he prescribed one grain. The apothecary who prepared the prescription put up ten grains. The medical officer was exonerated from all blame; but how was the marvellous stupidity of the apothecary to be accounted for? Some one suggested that the paper was folded *when wet*, an X being thus produced. But granting the correctness of this surmise, where was the man’s common sense? Being evidently unfit for his post he was removed. The unhappy medical officer—overpowered with vexation at the catastrophe—gave up the practice of his profession and took to one of the scientific branches.

The case illustrates, in a forcible manner, the necessity for carefully blotting a prescription, whether the explanation offered of the accident were true or not. At any rate it might have been.

I am, &c.,

CHAS. R. FRANCIS, M.B.,
Clapham Common, S.W., Surgeon-General.
Oct. 16th, 1882.

THE INFLUENCE OF LIGHT ON VARIOLA AND VACCINIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some years since I conducted a series of experiments (the results of which were recorded in your journal at the time) under the impression that the development of variculous pustules was favoured by cold, and retarded or prevented by heat, which further experience has convinced me has little or nothing to do in the matter, while light plays a most important rôle, as any one desirous of testing my assertion can readily ascertain for himself by comparing the results in two cases of vaccination, in one of which the arm is left bare, while in the other it is covered by some tissue capable of excluding the actinic rays of the sun; absolute darkness is unnecessary and undesirable, and the object desired can be attained without interfering with ventilation.

Prevention being preferable to cure, I shall continue to exclude the actinic rays of the sun from the rooms of such of my patients as chance to contract small-pox, and do not fear to compare results with those obtained from canterisation by carbolic or any other acid.

I remain, &c.,

W. T. GREENE, M.A., M.D.

Moirs House, Peckham,
Oct. 22nd.

MEDICAL PRACTICE IN CYPRUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having just heard that two or three surgeons are required for the island of Cyprus, I think it right to warn my younger brethren not to be tempted too hastily into consenting to go there, at least, until more liberal terms are offered. The utmost he can now expect there is about £200 a year, and without I believe any prospect of increase, and he cannot reckon on private practice, even if he could speak both Greek and Turkish. Now, the post of assistant-surgeon in a convict prison, at home, is worth at first £175 a year, besides free quarters and the privilege of having rations at contract price, while the salary increases £10 a year up to £250, whilst he will secure £450 on becoming senior surgeon. The duties of a D.M.O. in Cyprus are quite enough to absorb all his time in visiting the prison and attending dispensary daily, with long rides into the district, and then all the monthly reports. The salary ought I think to begin at £250, and increase yearly by £10 up to £300.

Yours, &c.,

ONE WHO HAS BEEN THERE.

October, 1882.

QUEEN'S COLLEGES IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Might I ask through your columns what is the meaning of the matriculation examinations as advertised at the Queen's Colleges? Are they accepted by all, and if not, by any; and if so, by what centres of final professional examination as a sufficient guarantee of the educational acquirements of the student?

The matriculation standard of the Queen's Colleges was low enough in all conscience before, but if their object is merely to qualify to enable those who "pass" to compete for the prizes, then good-bye to anything approaching a test as to a man's primary education.

Yours, &c.,

T. V. H.

Two New Antiseptics.

M. G. LE BON has just presented to the Academy of Sciences two new and very effective antiseptics—the glyceroborate of calcium and the glyceroborate of sodium. Both of

these compounds have the advantages of being very soluble, destitute of odour, and free from all toxic action. When exposed to the air, they both deliquesce with great rapidity, absorbing from the air an equivalent weight of moisture. Both alcohol and water dissolve twice their own weight of these salts. They are powerful antiseptic agents even in very dilute solution; the most effective in a therapeutic point of view appears to be the calcic salt. It is absolutely innocuous and it can be applied in strong solution to so delicate an organ as the eye without bad results. In a hygienic sense, both can be employed with advantage as disinfectants and as preservers of meat and other alimentary products. M. Le Bon has transmitted meat simply coated with a varnish of the glyceroborate to La Plata, and it has arrived in a perfectly fresh and sound condition. He thinks both salts will prove very useful as antiseptics in Lister's mode of dressing wounds.

Royal College of Surgeons, Edinburgh.—The following gentlemen having passed the Final Examination, were admitted L.R.C.S.E. during October:—

Clark, John Robert	Logan, John
Fletcher, Howard Bennett	Robertson, John Mair
Gettings, John Salter	Schmidt, Arthur Edwin
Hutchinson, Creighton	Snell, Walter Stannes
Kirkham, Frederick William	Wilson, William, M.B. and C.M.

King and Queen's College of Physicians in Ireland.—At the examinations for the Licences of this College, held on Monday, Tuesday, Wednesday, and Thursday, October 9, 10, 11, and 12, the following candidates were successful:—

For the Licence to practise Medicine—

Adcock, Henry, Liverpool	Jones, John Henry, Liverpool.
Harrington, John Mary, Tralee.	O'Donel, Claudius, Castlebar.
Hitchen, Thomas, Bradford.	White, John William, London.
Wright, William Henry, Liverpool.	

For the Licence to practise Midwifery—

Adcock, Henry, Liverpool.	O'Donel, C., Castlebar.
Bennett, W. Halloran, Dublin.	White, John William, London.
Harrington, John Mary, Tralee.	

At a special examination, held on Tuesday, September 19, the Licence to practise Midwifery was granted to—

Williams, John William, M.D., R.M.I., Dungarvan, co. Waterford.

The following Licentiates in Medicine of the College, having complied with the by-laws, have been elected Members:—

Burney, Walter C. S., Greenwich.	O'Meara, William H., Carlou.
Dyas, William, London.	Scott, John A., Freshwater.
Ffolliott, Frederick, London.	

French Hospital, London.—We are requested to announce that Mr. Henry de Mério has resigned his appointment as surgeon to the above institution.

Society for Relief of Widows and Orphans of Medical Men.—A Quarterly Court of the Directors of this Society was held on Wednesday, October 11, under the chairmanship of the President, Sir George Burrows, Bart. Two new members were elected. The death of one widow was reported, and two orphans had ceased to be eligible for further grants. Applications for grants were received from sixty-one widows, five orphans, and three orphans on the Copeland Fund, and it was resolved that a sum of £1,259 10s. be recommended for distribution at the next quarterly meeting. The quarterly expenses amounted to £34 17s. The state of the funds permitting, it was resolved, on the motion of the Acting Treasurer, to make a Christmas present to the widows and orphans in December next. The report of the Committee on the Revision of the By-laws was considered, and it was resolved that many important alterations should be submitted for approval to a general meeting of the Society.

Royal College of Surgeons, Edinburgh.—At the annual meeting of the College on the 18th inst. the following office-bearers were elected for the ensuing year:—President—William Turner, M.B. Secretary and Treasurer—Joseph Bell. Librarian—Archibald Dickson, M.D. President's Council—Henry D. Littlejohn, M.D., Patrick Heron Watson, M.D., David Wilson, M.D., Francis Brodie Imlach, John Smith, M.D., Douglas Argyll Robertson, M.D., Joseph Bell. Examiners—James D. Gillespie, M.D., Henry D. Littlejohn, M.D., Patrick H. Watson, M.D., David Wilson, M.D., John Smith, M.D., Joseph Bell, John Duncan, M.D., Robert J. Blair Cunynghame, M.D., Alexander G. Miller, M.D., Peter H. MacLaren, M.D., Johnston Symington, Robert Macnair, M.D. Dental Examiners—Patrick H. Watson, M.D., Francis B. Imlach, Henry D. Littlejohn, M.D., John Smith, M.D., Andrew Wilson, L.D.S., George

W. Watson, L.D.S. *Assessors to Examiners*—William Brown, James S. Combe, M.D., Benjamin Bell, William Walker. *Conservator of Museum*—Robert J. Blair Cunyng-hame, M.D. *Clerk*—James Robertson. *Officer*—Colin Mackenzie. *Assistant to Conservator*—George Reid.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ARMY MEDICAL EXAMINATIONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I should feel grateful to any of your readers who could—through the medium of your paper—supply me with the questions set at any one of the recent examinations for entrance into the Army and Naval Medical Services, finding that the authorities at Whitehall are unable to comply with the request.

I am, yours, &c., J. L. T.

Beaumaris, Oct. 23, 1882.

AN ABSENT MEMBER.—The reading of the paper was deferred till next meeting, the time having expired on the conclusion of discussion of previous papers.

MR. WALTERS (Leeds).—We do not prescribe; consult a qualified practitioner in your own neighbourhood.

AN ARMY MEDICAL OFFICER.—Thanks for the information; we referred to the matter in our last, and took occasion to draw the attention of an authority at head-quarters thereto.

ONE OF THE PUBLIC.—We do not care, as a rule, to reply to such questions; but in the present case there seems a reason why we should do so. We therefore assure you that you are entirely misinformed, and that absolutely no grounds exist to justify the insinuation you have brought. At the time when we unflinchingly exposed what we were convinced was a vicious state of things, there was, in our judgment, ample reason for the course we pursued. Since then better counsels have prevailed within the hospital, and it is no longer the scene of mismanagement and ruin it had for a season become. Under the restored *regime* order and submission reign in place of disorder and aggression, and all matters medical are rightly directed by the medical staff. You can accept our assurance on these points, and will probably, therefore, see the uselessness of proceeding any further with your scheme.

MANCHESTER.—The proposal is a very commendable one, and has our best wishes. We cannot, however, lend much assistance in the matter, since we had but a slight direct acquaintance with the deceased surgeon. That his friends will welcome the suggestion there can be no doubt, and from many you will certainly obtain valuable assistance in your labours.

A DOCTOR IN DISTRESS.—Unfortunately your case is not unique; several gentlemen like yourself, omitting to give the notice demanded, simply through being unaware of its having been demanded, have suddenly found themselves off the Register at a time when they particularly desired to be on it. You can put the matter straight again by entering on the Register.

A. W.—The letter shall be forwarded to the writer of the articles, who will judge of its contents.

MR. COURAYNE.—The case, judging from your description, is one of locomotor ataxy. The treatment is fairly good.

MR. ENGELS (Glasgow) is thanked for the very interesting cases to hand, which will appear shortly.

HOW INFECTIOUS DISEASES ARE SPREAD.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Whilst waiting to-day to see the troopers on their return from the war I looked round to examine the crowd, and was horrified to see a young fellow, probably of about seventeen or eighteen, with the skin all peeling from his hands, and with every appearance of having just got over the acute stage of scarlet fever. I lost sight of him before I could speak to him. Now, he was just in the condition to spread the disease. If I only saw this one case, how many more might not there have been about doing the same thing?

I am, Sir, your obedient servant,

October 20th.

A DOCTOR IN THE CROWD.

J. B. (Londonderry).—In a work of such magnitude it is impossible to avoid errors absolutely. The prescription in which Lij. quinine occurs is undoubtedly a misprint. We will draw the author's attention thereto, who will doubtless be glad to make the necessary correction in subsequent editions.

ANOTHER PHASE OF QUACKERY.—The manager of "The Blue Ribbon Army Brain Restorative Depot," Norwich, sends our publisher a long advertisement for insertion in our columns, with a request for terms for twelve months' insertions. We will make the manager a present of this notice, and at the same time would call the attention of the Public Prosecutor to the matter in order to stop the obtaining of money under false pretences. Many of those who join "Salvation" and other so-called "Armies," are not blessed with an overplus of brain power, and such catchpenny rubbish as "The Blue Ribbon Army Brain Restorative," at 11s. a bottle, may tempt these to part with their money in the hope of achieving greatness; for we are told in the said advertisement that "this Restorative has cured cases where men have afterwards risen to great eminence." Now, as the Blue Ribbon Army boasts of only a few months' existence, it follows that eminence can be very rapidly attained by sending 11s. to a cer-

tain individual at Norwich. But so happens that other wonderful things have come recently from that city of hallowed memories; it is therefore, time some official recognition were taken of those who thus generously seek to increase the brain power of the public for so modest a consideration.

DR. HERMAN (Finsbury) is thanked for his note.

DR. D. (London).—Report received; will appear as soon as space permits.

At the late "Primary" examination a "Bart's" man was asked by one of the examiners what structure he saw under the microscope. After looking for some time with great attention, the student brightened up, and as by an inspiration, replied, "Blood, sir!" "Blood, sir," said the examiner; "and how do you know that it is blood?" After some confusion the student said that a man who had just come out prompted him. "Quite right, Mr. —," smiled the examiner, "what he saw was blood, but you are now looking at a section of cartilage."

MEETINGS OF THE SOCIETIES.

HUNTERIAN SOCIETY.—This evening, at 8 p.m., Dr. Charlewood Turner will show a Heart of Two Chambers.—Dr. Herman, "On the Clinical Classifications of Backward Displacements of the Uterus."

QUEKETT MICROSCOPICAL CLUB.—Friday, Oct. 27th, at 8 p.m. Mr. T. W. Morris, "On the Fibro-vascular Bundles in Ferns, and their value in Determining Generic Affinities."

CLINICAL SOCIETY OF LONDON.—Friday, Oct. 27th, at 8 p.m. Mr. W. Asham, "On a Case of Gunshot Injury of the Lower Jaw."—Dr. Mahomed and Mr. Pepper, "On a Case of Ligature of the Common Carotid Artery for Hemorrhage from the Throat, due to Ulceration after Scarlet Fever."—Dr. Crocker, "On a Case of Haematuria from Bilharzia Hematobia" (specimens of the parasite will be shown).—Mr. Golding Bird, "On a Case of Removal of the Uterus for Fibroid Disease."

HARVEIAN SOCIETY OF LONDON.—Thursday, Nov. 2nd, at 8.30 p.m. Mr. Malcolm Morris, "On Chronic Ringworm."—Dr. Broadbent, "On Some Points relating to the Sounds of the Heart."

Vacancies.

Dental Hospital of London, Leicester Square.—Dental House Surgeon. Salary, £40. Applications to be sent to the Hon. Sec. on or before Nov. 13th.

Great Northern Hospital, Caledonian Road, N.—Ophthalmic Surgeon. Applications to be addressed to the Secretary not later than Oct. 31st.

London Fever Hospital.—Resident Medical Officer. Salary, £200, with residence. Applications to be sent to the Secretary on or before Oct. 31.

Magherafelt Union, Bellaghy Dispensary.—Medical Officer. Salary, £130, and £ 5 as Medical Officer of Health. Election, Nov. 6th.

Royal London Ophthalmic Hospital.—House Surgeon. Applications to be sent to the Secretary on or before Oct. 30th.

Appointments.

BARLING, H. G., M.B. Lond., M.R.C.S., Resident Surgical Officer to the General Hospital, Birmingham.

BUCHAN, W. A., M.B. Edin., House-Surgeon to the Clinical Hospital, Manchester.

CARLESS, G. N., M.B., Medical Officer to Her Majesty's Prison, Devon.

HALL, B., M.B. Lond., M.R.C.S., Assistant Medical Officer at Earlswood Asylum.

MACGILLIVRAY, C. W., M.D., Assistant Surgeon to Royal Infirmary, Edinburgh.

NEWCOMBE, F., M.R.C.S., Medical Officer for the Clifton District of the Newark Union.

SCOTT, C. C., M.B., C.M. Edin., House Surgeon to the Ayr New Hospital, and Surgeon to the Dispensary.

SPENCE, W. J., L.R.C.P. Ed., L.R.C.S. Ed., Resident Physician to the Bradford Infirmary and Dispensary.

STRAVENSON, W. E., M.B. Cantab., M.R.C.S., S.So. Cert. Camb., Electrician to St. Bartholomew's Hospital, London.

THOMSON, A. G., L.R.C.P. Ed., Medical Officer to the Hornsdown District of the Tonbridge Union.

Births.

BEVERIDGE.—Oct. 16, at Totnes, the wife of H. T. S. Beveridge, M.D. Edin., Staff Surgeon, R.N., of a daughter.

JONES.—Oct. 14, at North Park House, Harrogate, the wife of A. O. Jones, M.D., of a son.

RAVEN.—Oct. 19, at Broadstairs, the wife of Thomas F. Raven, L.R.C.P., of a daughter.

Marriages.

KENNEDY-HAYLE.—Oct. 17, at St. Mary's, Rochdale, William A. Kennedy, M.B., L.R.C.P., of Newcastle-on-Tyne, to Sarah, third daughter of Thomas Hayle, M.D. Edin., of Rochdale.

ROONEY-GERAGHTY.—Oct. 10, James Rooney, L.K.Q.C.P.I., Athboy, to Kate, only daughter of the late Laurence Geraghty, of Dublin.

Deaths.

COOPER.—Oct. 13, at Shelburne Road, Holloway, Charles Cooper, L.S.A. Lond., aged 70.

EDWARDS.—Oct. 13, at his residence, Colebrookdale, Shropshire, Benjamin Edwards, M.R.C.S., aged 67.

JOHNSTON.—Oct. 17, at Southsea, James Wingate Johnston, M.D., Inspector-General, R.N., Honorary Surgeon to the Queen.

RHODES.—Oct. 17, at Weymouth, Charles Rhodes, M.D., aged 41.

THE CAPACITIES AND FACILITIES OF EDINBURGH UNIVERSITY FOR MEDICAL AND SCIENTIFIC EDUCATION AND RESEARCH.

By WILLIAM RUTHERFORD, M.D., F.R.S.,

Professor of the Institutes of Medicine in the University of Edinburgh;
President of the Edinburgh Royal Medical Society, &c.

THE introductory lecture at the opening of the Edinburgh School of Medicine last week was attended by an overflowing audience of the profession and students.

The Teaching of Physiology.—At the outset, the Professor said that this being the first lecture delivered in the Physiological Department of these magnificent new buildings, it seemed to be his first duty to recall, in brief review, the efforts of those who so greatly assisted them in reaching this new era in the progress of the Edinburgh Medical School. An interesting historical retrospect was then entered into with regard to the early development of the Medical School of Edinburgh, the early efforts that were made in reference to the Chair of the Institutes of Medicine being particularly singled out and dwelt upon. He showed that, for nearly two centuries before a medical school was established in the University, medical education was given under the auspices of the College of Surgeons, and that the Town Council, about 1727, at the urgent request of four distinguished Scotch doctors who had returned from studying at Leyden under Boerhaave, founded the Chairs of the Theory and the Practice of Physic and of Chemistry, and of Medicine, Anatomy, and Surgery, Botany and Materia Medica, and Midwifery. With these branches of instruction a school was formed in which a regular system of medical instruction was for the first time carried out in Edinburgh. It was, then, to Leyden and the educational system of Boerhaave that they owed the titles of two of their chairs—Institutes of Medicine and

Practice of Physic. The institution of professorships of pathology and clinical medicine rendered both titles obsolete, and they would doubtless one day be changed for the simpler appellations, physiology and medicine. Touching next upon the former professors of the Institutes of Medicine, from Dr. St. Clair to Hughes Bennett, he showed, by quotations from their manuscript lectures, preserved in the library, that on many points their teaching was in accord with the explanations of modern physiology. To Dr. John Hughes Bennett, who occupied that chair from 1848 to 1874, he said the development of the physiological department in that School was largely owing to his energy. He was the first in this country to institute a course of practical physiology. He induced the Senatus to provide him with a collection of physiological apparatus, together with the laboratory in the old buildings, which, until a few years ago, was sufficient for the wants of the School. And no one need question that what was done in that laboratory under his superintendence contributed not a little to the growth of their School, which eventually rendered the old laboratory and lecture-room altogether inadequate. During the past few years, owing to deficient accommodation, their teaching had been carried on under difficulties which have seriously tested the endurance of everyone engaged in it.

New University Buildings.—The Professor then continued—But now at last we are nearly all housed in this palatial edifice, which everyone acknowledges to be worthy of our fair city. We know that the people of Scotland look with an eager eye at every institution destined for an educational purpose. We know that they look with pride at the success of their Universities because they bring the advantages of all their elaborate machinery of education in science and letters within reach of those whose means may be small. And we know that those more immediately interested in this University are gratified at witnessing the remarkable development which has of late years taken place in her Medical Department, and which has rendered these

new buildings necessary. We thank the public and the Government or the generous manner in which they have contributed the funds required for our new Medical School. We have to thank the Principal of the University and the other members of the Building Committee for their unwearied efforts to ensure success in this great undertaking, and we have to thank the able architect, Mr. Anderson, for the great beauty of his design, and for the skill with which he has met the demands for accommodation—often elaborate and complicated—made by the Professors for their several departments. I have, indeed, special reason for thankfulness to the Building Committee for the liberal manner in which they permitted my elaborate designs for this extensive department to be fully carried into effect. Some, I dare say, felt disposed to question the need for a Physiological Department so extensive, but they generously gave me the benefit of the doubt, and allowed me to be the judge of what was requisite.

New Physiological Department.—I am confident that when you have become practically acquainted with this department, you will testify that it is well adapted to enable you to gain a knowledge of physiology, and equally well adapted to enable research to be prosecuted in all the varied branches of physiology. On the ground floor stands this capacious lecture-room, with museums for apparatus, diagrams, and other teaching appliances. On the floor immediately above this you will find the laboratory and retiring rooms. The laboratory consists of three divisions:—The first comprises five apartments adapted for microscopical study and research. The largest room is used by the Histological Section of the Class of Practical Physiology. In that room you will be trained to prepare and examine with the microscope the several tissues and organs of the body in their normal condition. The second apartment is a laboratory for microscopical research; a third is intended for the increasingly important subject of microphotography; a fourth is for microscopical demonstrations; and the fifth is to be used as a students' common room, for reading, and for work connected with microscopy. The second division of the laboratory is intended for study and research in physiological, and what is sometimes termed pathological, chemistry. It comprises four apartments. The largest is intended for the Chemical Section of the Class of Practical Physiology. You will find there all the appliances needed to enable you to gain a practical acquaintance with the main facts of physiological and pathological chemistry, chiefly those facts and those chemical methods which are of service in medical practice; a second room is equipped as a laboratory for special research in physiological and pathological chemistry; a third is a room for gas analysis, such as is needed in physiological chemistry; the fourth is a general chemical preparation room. The third division consists of rooms devoted to practical teaching and research in physiological physics and allied subjects. One room is intended for experiments on muscle and nerve, on the circulation and respiration, animal heat, and other subjects. A second is intended for optical and other studies, which you can at any time prosecute individually, such as the practice of the ophthalmoscope and laryngoscope, the sphygmograph, cardiograph, and other instruments. The museum for apparatus has also been specially adapted for experiments on animal electricity, and also as a room for giving practical instruction on the electrical apparatus used in medicine and in other subjects to the Class of Practical Physiology. Some, who appear to labour under the delusion that the word physiology signifies experimenting on living animals, have indicated their astonishment that so much space should be devoted to such a purpose, and have inferred that the great extent of this laboratory must imply a great increase in the number of experiments on living animals performed in this school. That is an altogether erroneous idea. Experimenting on living animals is but a small part of the

work of the practical physiologist. He has the wide fields of microscopy, of physiological chemistry, of physiological mechanics, hydraulics, optics, acoustics, thermo- and electro-dynamics. When experiments have to be done on living animals, many can be performed in a state of insensibility. Only a few require the animal to be sensible. No painful experiments for teaching you the already ascertained facts of physiology are ever performed in this class. The experiments on animals not anaesthetised have—taking the average of the past eight years—been few—indeed, too few—in number, and they have only been performed by fully-qualified medical men for the sole purpose of original research. I, therefore, think that the public may safely leave this matter in our hands, to be dealt with as the necessities of the case may from time to time appear to demand.

The Endowment of Research.—But, gentlemen, our laboratory is not yet complete; we are in need of endowments for skilled assistants, to undertake and to assist in superintending research in physiological chemistry, physiological physics, and microscopy. Three such men are to be found in the physiological laboratories of Leipzig and Berlin, where they are supported by Government; and they are necessary in any fully-appointed physiological laboratory. Endowments are also needed for fellowships, to be held by those willing to devote their time and talents to the unselfish object of scientific research; and endowment is also needed to provide the materials required to carry out the work. Scientific investigators receive some assistance from the yearly grant given by the Government to the Royal Society of London for distribution to a few of those who are desirous of undertaking expensive research; but the sum is altogether inadequate. Considerable assistance has also been rendered by the British Association and British Medical Association, who have generously helped scientific workers from their limited funds subscribed by medical men, and by those who work at science, or are interested in its progress. But from none of these sources can assistance be obtained to do more than pay for the materials used in a comparatively small number of investigations. The investigator must always do the work for nothing; and too often it happens, and it is especially apt to happen at the outset of life, that a man cannot afford to spend months, and it may be years, in toiling arduously without earning the bare means of subsistence. The only satisfactory way in which the difficulty can be surmounted, the only really practicable manner in which research can be endowed, is to give to universities and similar institutions adequate sums of money to be allotted to such men, and for the attainment of such objects as the authorities in the several centres may deem worthy. What we so much require in all our laboratories, and, indeed, in relation to all our chairs, are working fellowships, each with a small annual salary sufficient to support the holder while he devotes his time and strength to research. That would enable the University authorities, not only to produce far more research than is now possible, but also to encourage young graduates who have given proof of earnestness, of exceptional ability, and of a desire to prosecute original inquiry. Our University has no funds available for that object, and we must, therefore, await the liberality of those who know that research signifies a search for the truth in everything, who are aware of the arduous nature of the undertaking, its unselfish objects, and the unspeakable blessings it has conferred, and will ever confer, on the whole human race. Already the first step towards the realisation of this wide scheme has been taken by a liberal gentleman, who, while he withholds his name, generously gives five hundred a year for three years—(applause)—as a preliminary experiment to endow for that time five working fellowships, each with the moderate salary of one hundred a year. These appointments have just been made for the first time, and we are all sanguine that the

results will be such as we anticipate. But while it is so important to give support to those anxious to do research, it must not be forgotten that it is equally necessary to support the laboratories in which their work is to be done with the aid of costly apparatus and costly materials. Ere we can hope, however, to see, in the several laboratories of these new buildings, a band of investigators, supported by endowments, it will be necessary first of all to procure the large sum yet required to finish the buildings. It is, I fear, only too true, that contributions to these far from completed buildings have been lost, in consequence of the tumult regarding experiments on animals. We were offered by a lady the bribe of a great contribution which possibly might have completed the buildings, if we would only consent to abandon experiments on living animals. We declined the offer to sell our independence. We conceive it to be our duty to advance the science and art of medicine by every legitimate means. We will never renounce that duty. But, gentlemen, I need not detain you further on this question, for our learned Principal, who has always striven so successfully and so unselfishly on behalf of the University, will lay this important matter ere long before the community. The Professor proceeded to impress upon the students that the great object of these new buildings with their elaborate appliances for giving systematic and practical instruction in medical science, was to enable them more easily than hitherto in that school to become "reasoning practitioners of medicine." The great object was to educate pupils to become not rule-of-thumb empirics, but reasoning practitioners; men whose minds had been trained to analyse complicated phenomena, who had learned how to appreciate their importance, who should be able to give a clear, well-balanced, cautious judgment regarding their significance and the manner in which they should be treated. Scientific medicine altogether differs from a trade, or a merely mechanical art. There was only one scientific method of learning it. They must study the theory before they could understand the practice. They must begin at the foundation with anatomy, chemistry, physics, and general biology. They must then study physiology, pathology, the nature of remedies, with their actions in physiological and pathological conditions of the organism. All these were needed to furnish the theory or institutes of medicine. Then they would be able to understand the practical aspects of surgery, medicine, and so to become reasoning practitioners and independent thinkers. The lecturer then gave a brief account of the mechanism of the organs of sensation. He showed why the physiologist maintains that sensation results from the activity of nerve cells; and how our knowledge of the telephone is calculated to alter existing theories regarding the action of the organ of hearing.

A DEFENCE OF VIVISECTION. (a)

By JOHN CLELAND, M.D., F.R.S.;

Professor of Anatomy in the University of Glasgow, formerly Professor of Anatomy in Queen's College, Galway.

PROFESSOR CLELAND said that the study of experimental philosophy in this country was eminently unpopular. It could not be expected to have much sympathy from the public, for the simple reason that the general public cared nothing for any truth or science for its own sake, but only for the so-called practical benefits to be derived therefrom, while Science refused to smile on those who loved her merely for her fortune. It was perfectly well known to the more experienced members of his audience that without experiment the information which they were able to turn to account for the cure of suffering either in domestic animals or man, could not exist. Whatever might be the pain to the victims of

physiological experiment—and that had been grossly exaggerated—those experiments were never performed but with the view of obtaining and spreading a more accurate and complete knowledge of the processes of life. Now, he wished to point out that those who had legislated against experiment—the members of the two Houses of Parliament—were the great majority of them sporting men. He had no feeling against sport, at least in some of its forms. He could not help remarking, however, that the more innocent forms of amusement of our legislators not only involved that kind of cruelty which their legislation professed to wish to put down, but required for their enjoyment an utter carelessness for the fate and feelings of their victims. What, for instance, could be said of fox hunting and hare coursing? He wanted to know how in the face of those things the legislators who passed the Act for the curbing of physiological experiment could reasonably object to the charge of hypocrisy. The highly-wrought pictures often drawn of the sufferings of animals from experiment and otherwise were full of exaggerations depending on the ignorance or want of consideration of those who drew them. He would only say that a large number of so-called vivisections were, so far as the sensations of the animals were concerned, the mere infliction of death in the most painless manner possible. If the matter was critically looked at, it would be found that the evidence was distinctly to the effect that their capability of feeling pain was, even in the higher domestic animals, far less than in man. In the first place the skin was very different from that of man. It was well known that in operations on the human subject the skin was the structure whose injury gave most pain. The mere division of the deep structures with a sharp instrument would appear to cause little or no pain, except in the case of nerves. When there was much pulling or violent tearing there might be great pain; but that muscles, vessels, and connective tissue might be handled and divided without causing any suffering comparable with what was occasioned by division of the skin was a recognised fact. When, however, they came to consider the integument of domestic animals it was not difficult to make sure that one had a much less sensitive structure to deal with. Its microscopic as well as its obvious appearance warranted one in expecting that it would be so; and while neither a horse, nor a dog, nor a rabbit was at all slow to make people distinctly understand when it was hurt, it became evident from the absence of signs of pain when skin wounds had to be made on them, that they suffered from them very little indeed. When, in various experiments which had greatly advanced physiological knowledge, the pneumogastric nerve of a rabbit was cut down on, supposing the animal not to have been chloroformed, it would be seen to suffer little inconvenience from the skin wound, and none from the search among the structures underneath; in fact, obviously much less annoyance than it would suffer from the administration of chloroform, which, strange as it might seem to some ladies, it abominated. But when the nerve was divided a sharp cry of agony at once told not only the moment of agony, but how far the animal had previously been from anything of the sort. Happily it ceased on the instant, and the rabbit showed no further discomposure. He said people must guard against estimating the pain by the outcry made. Speaking of the pain itself, apart from the power of bearing it, he did not think there could be any serious doubt that the pain occasioned by a given amount of lesion varied according to the fineness of the impressibility of the nervous system, and that civilisation and education, as well as certain alterations of nutrition in disease, did greatly enlarge the capacity for feeling pain. The amount of intelligence had an important bearing on the character of the pain possible to an animal. The actual pain produced at the moment by a physical lesion constituted but a small portion of the idea of pain as it presented itself to the mind of man. The accessories of anticipation, memory, and associations

(a) An Address delivered Oct. 24th, in the Royal Veterinary College, Glasgow.

played an important part, and it was the effect of the images presented by these to the mind which gave rise to all the suffering termed horror. Doubtless the more intelligent mammals had both memory and association of ideas largely developed. But as to anticipation, they had no chance of such a thing in a properly-regulated laboratory; and his contention was that, in the brutes, anticipation, memory, and association had a so much less amount of mind than in man for their origin and operation, that the images which they produced must be both much fewer and much less wrought up into horrible phantoms; in fact that we cannot well estimate how much of the complex machinery of pain, as we know it, the lower animals were altogether free from. At the same time, it was perfectly evident that large capacity for pain was left to such animals as the horse and the dog, that it might be safely affirmed that no one, at least no physiologist, would choose those animals for an experiment which could equally well be performed on a less highly organised animal. However, no one could doubt that the mental constitution of a rabbit was so limited that it was quite incapable of the suffering of which a horse or a dog was capable. Turning to the cold-blooded animals, the line of argument which he had pursued became enormously more important. The consciousness of a frog was something so far removed from that of a human being that it was impossible to imagine any condition of our minds to liken to it. That might be taken as certain from the imperfect development of its brain as compared with the brains of higher animals. The organisation of fishes was even lower. He was not an experimenter on animals, and had no personal interest to serve in the remarks which he had made, but it was certainly the duty of those who were thus free, and who, from the nature of their pursuits, were familiar with the magnitude of the debt which humanity owed to experiment, to aid in opposing, so far as they could, the spirit of persecution against experimenters. In the economy of the world pain had its place. But if it were in all circumstances wrong to inflict it, it could not have existed under the domination of an all-merciful God. The comparative importance of ends must be constantly kept in view; and surely those whose science, founded on experiment, had spread its beneficent influence over man and beast, and gained for them all the alleviation of suffering which had been gained, might be held to endorse, more effectually than the president of the Anti-Vivisection Society, the sentiment toward the close of his illustrious relative's immortal poem directed against the senseless slaughter of birds for mere amusement.

FUNICULUS SCLEROTICÆ: A VESTIGE OF THE FŒTAL FISSURE IN THE HUMAN EYE.

By ADOLPHE HANNOVER, M.D.,

Professor of Anatomy in the University of Copenhagen.

Translated by J. F. KNOTT, M.K.Q.C.P.I.,

Fellow and Senior Demonstrator of Anatomy, Royal College of Surgeons, Ireland.

In a memoir on Coloboma oculi I have represented this condition as a formation resulting from an arrest of development, and due to incomplete closure of the fissure which, during fœtal life, exists in all the ocular membranes, as well as in the vitreous body, ciliary body, and iris. On this account I have designated Coloboma as a great fœtal eye, in which the embryonic type persists in all its details. In the normal eye of adult life but one constant trace of the fissure alluded to has hitherto been recognised—the *macula lutea* with the *fovea cæca*—and in my memoir on the retina of man and vertebrate animals, I have also arrived at the conclusion that the *fovea cæca* is not only a formation due to an arrest of development, but is also the most defective part of the whole retina.

Since this date I have succeeded in discovering in the human eye another vestige of the fœtal fissure, to which

I have given the name of *Funiculus scleroticæ*. In making a vertical section of the sclerotic exactly behind the *fovea cæca*, we find in its interior a solid cord, which passes through the fibres of the sclerotic; sometimes at right angles, sometimes with a slight obliquity. On examination with the naked eye, its limits are found to be pretty well-defined, and when viewed with a slight magnifying power we find that the fibres of the sclerotic pass in rounded bundles to be attached to its outer surface. Their course is, however, abruptly interrupted in this situation, so that the same bundle cannot be continuously traced on both sides of the cord. The thickness of the latter varies a little; it is usually that of a fine sewing thread. The anterior extremity of the cord, which is placed towards the interior of the eye, is usually somewhat thicker, and adheres pretty closely to the external surface of the tunica choroidea by a trumpet-shaped expansion. Sometimes it presents a hemispherical elevation, and we may find some free filaments in this situation, which are detached from the choroid. The posterior extremity of the cord also presents an enlargement, especially towards its inferior aspect, and after a course of greater or less length it is lost in the cellular tissue which covers the outer surface of the sclerotic coat. We sometimes find this extremity hanging free from the outside of the latter. The greater thickness of the anterior and posterior extremities may increase to such an extent as to give to the whole cord the form of an hour-glass, when it is markedly constricted at the middle of its course. The sclerotic, at the place where it is traversed by this cord, is usually concave, both on its anterior and posterior surfaces, so that the total thickness of the tunic is diminished in this situation. Sometimes the position of the anterior extremity of the cord is indicated by a flattened depression, or a small plaque on the inner surface of the sclerotic, or by a variation of the colour of the pigment more or less slight. We rarely can distinguish in this situation a depression on the outer surface of the sclerotic; the depression is sometimes flocculent or rough, while the surrounding surface is uniform in appearance.

When more highly magnified, we find that the cord is finely striated in a longitudinal direction, and is made up of fibres which decussate with those of the sclerotic. The fibres are very fine and soft, and describe slight sinuosities, or are united in bundles, and are covered by a considerable number of small angular nuclei. They are easily distinguished from the thicker and stiffer fibres of the sclerotic, and are imbedded in a compact homogeneous mass of greyish-white colour. There are no meshes similar to those of the sclerotic fibres, and they are very hard to separate from one another.

The funiculus scleroticæ is constant; I have examined 50 to 60 human eyes, both of adults and of infants, in none of which it was absent. Eyes with thick sclerotic coats should be chosen in preference, and it is well to harden them in chromic acid diluted with water, because it is then easier to make thin sections. On account of the frequency with which the funiculus takes an oblique or undulatory course, it often happens that we cannot succeed in exposing the whole by a single section; a portion remaining covered by the fibres of the sclerotic, between which it appears to be lost.

The funiculus scleroticæ cannot be confounded with any other structure in the sclerotic, notably with the vessels and nerves which traverse this tunic. The canals which transmit the latter appear, on transverse section, as openings of round or oval form, and are covered on their inner surface by sinuous fibres of cellular tissue. They do not interrupt the course of the fibres of the sclerotic, they merely pierce through the latter, and transmit but vessels and nerves. We never find there a solid cord like the funiculus.

Although the funiculus scleroticæ is not absent, it nevertheless presents, even in the eyes of the same subject, variations in form, in size, and in course. We have already mentioned the hour-glass form. It is sometimes directed horizontally forwards, sometimes

more obliquely, or describes an S or a convex arc. It may bifurcate near the inner surface of the sclerotic. In some very rare cases two or three thinner bundles are found, which appear to be rudimentary cords, and are placed at the side of, or above, or below, the normal cord. Instead of the solid cord I have in one case met with a group of fibres in the form of a vortex, which seemed to come from two or three irregular cords. Lastly, in adult life, we may even find an indication of the formation of vessels in the interior of the funiculus. The funiculus was, in fact, at its origin permeable, and contained one or two vessels. The proof of this is, that at first, in some adult eyes, I have, in very thin sections of the funiculus, been able to see by transmitted light the remains of a vessel, which was recognisable by the double contour of its walls, and a very delicate, serrated, transverse striation; the vessel itself was closed. Besides, we are able (and also in case of adults), separately from the funiculus, to determine the existence of two or three true vessels at the outer surface of the sclerotic, where a fissure may also be found, which, however, does not in any case penetrate more deeply. In the eyes of newly-born infants I have often been able to detect an opening at the extremities of the funiculus, which was closed in the rest of its course, and we may similarly find, as in cases of adults, open vessels in this situation placed beside the impervious funiculus. Finally, in some eyes of newly-born children I have found the whole canal open and covered with fibres of cellular tissue, as is the case with other openings which give passage to vessels and nerves in the sclerotic. Apart from this particular, the funiculus in newly-born children is similar to that of adult life, excepting that it is sometimes harder to observe, when the sclerotic is thinner in its entirety. All these differences in the new-born, and, to a certain extent, in the adult also, must be referred to a different point of arrest in the development of the funiculus, of which the primitive cavity becomes closed sooner or later, but is as a rule obliterated at the time of birth.

We are also able to find traces of the ocular fissure in other parts of the sclerotic which lie in the neighbourhood of the funiculus. We have already said that the internal surface of the sclerotic in adults may present a slight concavity just behind the fovea; and, that the posterior surface of the funiculus, in some rarer cases, is also indicated by a depression on the outer surface of the sclerotic. Those characters are still more strongly pronounced in the eyes of the new-born. Not only do we then meet with similar depressions, but the whole region from the entrance of the optic nerve and horizontally outwards to a point beyond the entrance of the funiculus, may be marked by a furrow, as well on the internal surface of the sclerotic as on the external, and the sclerotic may be appreciably thinner in the whole extent of the region formerly occupied by the foetal fissure, which is not the case in the eyes of adults. In *Coloboma oculi*, I have shown that the very prominent protuberantia scleroticalis which on the inner surface of the sclerotic appears as a deep oval fossa, and the thinness of the membrane in this situation, are the result of an arrest in the closure of the ocular fissure (*Über den fötalen Zustand des Auges bei der Form des Coloboma*; *das Auge*, 1852, p. 99, Pl. III. fig. 23).

The choroid which is fixed to the internal extremity of the funiculus, presents in its own substance but little trace of the formation of a cicatrix or raphe; it is usually a little thicker in the direction of the macula as well in adults as in the new-born. On the other hand, we may often be able to determine the existence of traces of a raphe in the distribution of the vessels.

As the anterior extremity of the funiculus is firmly bound to the choroid, it is probable that, before birth, one or two vessels passed at this point into the choroid, where the latter has, in all likelihood, been also fissured; and having regard to the close adhesion of the choroid to the fovea caeca, it is even probable that the vessel penetrated completely through the continuity of the fissure

in the fovea caeca, and possibly into the vitreous body beyond.

In monkeys I have had the opportunity of examining the eyes of only three individuals—*Cercopithecus fuliginosus*, *Macacus cynomolgus*, and *Macacus nemestrinus*. In all I have found distinct traces of the fissure of the sclerotic, for in an extent of 4.5 mm. horizontally outwards from the optic nerve, on the internal or external surface of the sclerotic, or on both, there was a furrow where the sclerotic was found to be thinner and more transparent when held before the light. At the external extremity of the furrow, or a little to one side, was found the opening of a vessel of considerable size, which traversed the sclerotic very obliquely, so that its opening at the external surface of the sclerotic was 1.15 mm. nearer the optic nerve than the opening at its internal surface. Many smaller vessels may also be present in the furrow, or beside it. The vessels were open and filled with coagulated blood; the great vessel was not yet transformed into a solid cord.

AORTIC ANEURISM OPENING INTO THE ŒSOPHAGUS.

By Surgeon-General C. R. FRANCIS, M.B. Univ. Lond., M.R.C.P. Lond.

MR. C. was my immediate neighbour at a village in Surrey in 1878. He was a patient of mine, but his wife had her London physician. She was a confirmed invalid, though able to walk about occasionally and enjoy the pure country air. Mrs. C. was said to be suffering from "enlarged heart," and was accordingly very careful of herself. It was generally believed that she made the most of her ailments, and that there was a strong infusion of the hysterical element in the case. The "spinal irritation" of which Mrs. C. also complained was attributed to the same cause. She was in her 50th year, twenty-five years married, but without family. The temperament was markedly lymphatic. Her health had always been good, until about seven years previously, when she began to ail. There were no very tangible symptoms for two or three years, nothing beyond a feeling of *malaise* and a sense of indescribable discomfort. Her friends pooh-poohed the idea of there being any disease, and urged her to rouse herself. Then dyspeptic troubles began. Now anorexia, now uneasiness after eating, now cardialgia, with occasional flatulence, were the prominent symptoms. About a year before I saw her, or six years after the commencement of her ailments, Mrs. C. had been recommended to go through a modified course of gymnastic exercises. She did so, but was decidedly worse afterwards.

One Sunday afternoon Mrs. C.—having hitherto resisted her husband's wish that I should be consulted—consented to see me, and I went over and had a long chat with her. She had been in bed for some days complaining of weakness and increased palpitation; latterly she had suffered somewhat from this, but not much. In addition there was now a new symptom—a sense of constriction of the gullet, which almost prevented the food from passing through into the stomach. It being my first visit, I did not, from motives of delicacy, make any manual examination. I accepted, for the time, the diagnosis already made by others, intending to make one for myself the following day. Believing with the medical men who had already seen her that there was a good deal of nervous irritability in the case, and attributing the spasmodic constriction of the œsophagus to the same cause, I prescribed full doses of hypophosphite of lime, and left Mrs. C. very much cheered by my visit, so much so that she actually, to the surprise and delight of everybody, came down stairs for two or three hours in the evening into the drawing-room. I had to go to London early the following morning. Mrs. C. had passed a fair night, and was feeling somewhat better. On returning home in the afternoon my wife met me at the door with a very blank face. Mrs. C. was dead;

she had died suddenly about 3 p.m. She had remained in bed all the morning, and everything had gone on as usual. Between 1 and 2 p.m. she had rung for her lunch, and had it placed on a table by her side, saying that when anything more was wanted she would ring again. A considerable time having elapsed without any signal coming from the sick-room, Mrs. C.'s niece went in to see, and to her horror saw that all was over.

On going over myself, I met another medical practitioner who, in the emergency, and during my absence, had been summoned. On arrival he found that life must have been extinct for some little time. A little blood and mucus were on the night-dress and the side of the bed, towards which Mrs. C. had evidently turned, in view, doubtless, to vomit, as she must have felt sick.

Clearly there was internal hemorrhage. A post-mortem examination was made in my presence the following morning by the gentleman above-mentioned and his partner. An aneurism of the arch of the aorta had burst into the œsophagus. Unfortunately, the vessels were not examined beyond the seat of the aneurism. There were, however, no indications of disease. *The heart was small, with more fat than usual.* The body generally was well nourished. The cause of death being ascertained, it was unnecessary to make any further examination.

Remarks.—The sudden death naturally took every one by surprise, and no one more so than the poor husband, who, though he quite felt that the case was hopeless, would have been thankful to be prepared for the event. After all, there was no hysteria whatever, but all the symptoms, objective and subjective, were due to the growing aneurism pressing upon and causing the "spinal irritation," pushing forward the heart, and, by increasing the impulse, conveying the idea of enlargement. It is probable that the ear was never applied to the seat of the spinal irritation, as towards the last, certainly, if not earlier, a bruit must have been very audible. Does not the case teach us never to take anything for granted, but to bring every faculty we possess to our aid in the investigation of disease? In this connection I may mention a case that came under my notice in India. A gentleman in Government employ consulted the civil surgeon of his station for "indigestion." After he had been under treatment for some weeks without any manifest improvement, the civil surgeon determined to have a thorough physical examination. On taking off his coat and waistcoat and appearing down to the waist *in puris naturalibus*, mitral disease was discovered; there was a powerful impulse, with some displacement; but the patient was cognisant of nothing abnormal, and became naturally, and with good cause, very much concerned when his true condition was pointed out to him. He had been, and was then, a very active racket-player; and he expressed his great unwillingness to abandon this, his favourite pursuit, even though continuing to play might cost him his life. He was now taken under treatment for disease of the heart. I am not acquainted with his ultimate fate, as I soon after left the station.

Clinical Records.

GLASGOW ROYAL INFIRMARY.

Case of Sebaceous Cysts of the Prepuce resembling Epithelioma.

Under the care of Dr. DUNLOP.

Reported by A. J. ENGELS, House-Surgeon.

H. G., æt. 50, tailor, was admitted on the 28th September, 1882, into Dr. Dunlop's ward. Two years ago (shortly after his wife's death), patient noticed two pimples on the prepuce close to the corona, which gradually increased without pain. He sought medical advice and the growths were removed by the knife. He states that afterwards various lotions were applied. For a short time he was relieved, but the growths re-appeared. On admission into the hospital these were the size of small nuts, hard and horny to the touch,

and on pressure the one on the right side discharged pus. Slight enlargement of a gland, midway between the superior spine of the ilium, and the symphysis pubis of the right side. No history of syphilis. Family history satisfactory.

Sept. 28th.—Patient being under the influence of ether, Dr. Dunlop applied the thermo-cautère round the edges and base of each growth and removed them, and the part was dressed with carbolic oil.

On examination, after removal, the tumours were seen to be cysts containing sebaceous matter undergoing change.

Tramway-Car Accident—Smash of Elbow-joint—Fracture of Base of Skull—Amputation of Arm—Recovery.

Under the care of Dr. DUNLOP.

Reported by A. J. ENGELS, House-Surgeon.

J. McL., æt. 17, strapper, was admitted on September 4th, 1882, into Dr. Dunlop's wards, suffering from a fracture of the lower end of the humerus, displacement of both bones of the forearm, with separation of the periosteum from the bones, extensive bruises and laceration of the soft tissues. There had also been some hæmorrhage from the left ear before admission into the hospital. On examination of the head a swelling was found over the occiput, and the patient seemed to feel pain when the hand was placed over the left side of the frontal bone. Pupils were equal on admission. Patient was in a semi-comatose condition, but gave incoherent answers when loudly spoken to. His friends state, that he met with his accident by jumping from the front of a car when in motion, and was knocked down by another one coming in the opposite direction, the guard of the wheel striking his head, and the wheel itself passing over the elbow. Dr. Dunlop being sent for, decided to amputate the arm in the middle third; the operation was performed with antiseptic precautions, patient being under the influence of chloroform.

Sept. 5th.—Temperature, morning, 100·8; evening, 101·8. Patient passed his fæces and urine in bed. Left pupil slightly contracted.

From September 6th to the 21st, the temperature varied from 102·2 to 99·2, after that it came down to normal, the highest being on the morning of September 6th, namely, 102·2. A laxative always brought down the temperature.

9th.—The dressings were changed for the first time, and the stump was looking well. Very little discharge; very slight sloughing of the flap in the neighbourhood of the drainage tube.

17th.—At the third dressing the drainage-tube, and the stitches were removed, and the slough had separated, leaving a small, healthy, granulating surface.

20th.—Patient became more conscious of his surroundings, and began to give more sensible answers when questions were put to him.

24th.—At the fifth dressing the antiseptic treatment was changed to boracic lint dressing, which was continued every second day.

29th.—Up to this date patient had no control over his bowels or bladder, but to-day he asked when he required to micturate or pass a motion.

Oct. 7th.—Patient was allowed up for the first time, and is now doing very well. Stump almost whole.

16th.—Dismissed, well.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 27, 1882.

The President, Professor LISTER, F.R.S., in the chair.

Mr. W. J. WALSHAM on a

CASE OF GUNSHOT INJURY OF THE LOWER JAW.

H. W., a woman, æt. 20, was admitted into the Metropolitan Free Hospital, under Mr. Walsham's care, on July 16th, having been shot at with a revolver. The wound was situated about an inch above the angle of the jaw, and passed in a direction backwards, inwards, and upwards. The wound was enlarged, and the jaw was found perforated. The finger could be passed as far as the first inter-phalangeal joint, but neither with it nor with a probe could the

bullet be felt. On examining the mouth a slight fulness above the right tonsil was seen, but there was no wound or definite indication of the bullet. Considering the importance of the structures amongst which the bullet was evidently embedded, it was not deemed prudent to endeavour to extract it. The patient was quieted by opiates, and water dressings were applied to the wound. Considerable swelling about the angle of the jaw in the region of the tonsil supervened, accompanied by a constant dribbling of saliva from the mouth. On the 25th a spiculum of bone, accompanied by a small portion of the crown of the wisdom tooth, and on the 26th the bullet, with the remainder of the wisdom tooth embedded in it, were discharged. The patient progressed satisfactorily, and left the hospital on August 16th, with the wound nearly healed. Mr. Walsham remembered that, in addition to other points of interest, the chief lay in the question of treatment. Three distinct courses presented themselves—to attempt the extraction of the ball through the external wound, to cut down upon it and remove it through the mouth, or to leave it in the hope that it might escape spontaneously or become encysted. The objections to the first were that a large portion of the jaw would have to be cut away to obtain room for the necessary manipulations, that the exact situation of the bullet was not known, and that there would have been considerable risk of wounding some of the large vessels and nerves through which the bullet had evidently passed. Against the plan of removing it through the mouth the fulness about the tonsil did not seem to point sufficiently clearly to that being the situation of the bullet to justify an incision in such a dangerous situation. The course pursued in face of these considerations was to leave the bullet to come away spontaneously.

The PRESIDENT remarked that the case afforded a remarkably interesting example of perforation of this bone without fracture, which was most unusual. He thought the treatment pursued was appropriate, for it was true that less danger might be apprehended from the presence of a bullet in such cases than from the disturbances set up by searching for it, this course of proceeding being inexpedient when the situation of the missile was a doubtful matter. He thought the case was a very favourable one for the adoption of antiseptic measures of treatment, whereby risk of secondary hæmorrhage would have been much reduced.

Mr. WALSHAM said the difficulties in the way of pursuing such treatment had deterred him from the attempt.

Dr. MAHOMED read the notes of a case in which Mr. A. J. Pepper had

SUCCESSFULLY TIED THE COMMON CAROTID ARTERY FOR SEVERE BLEEDING FROM THE THROAT AFTER AN ATTACK OF SCARLET FEVER.

C. W., æt. 30, was admitted under the care of Dr. Mahomed on Jan. 2nd, 1882, suffering from scarlet fever, which ran a simple course with ordinary convalescence until Feb 22nd, when the patient shivered and complained of sore throat. Temp., 101.6° F. On morning of 23rd the uvula was large and translucent, and there was redness and swelling of the soft palate. On 24th he complained of great difficulty in swallowing, and throbbing of left side of throat. Two hæmorrhagic patches had appeared at the junction of the hard and soft palates, with a large gelatinous bleb on the left side. Three hours later the throat, especially on left side, became rapidly swollen, accompanied by a feeling of suffocation; soon after patient brought up a considerable quantity of blood; the swelling and difficulty of breathing subsided; at the same time the hoarseness passed quite suddenly into complete aphonia, which persisted. The alternate enlargement of the neck, hæmorrhage and subsidence of the swelling, were repeated several times until the morning of the 27th, when the patient's condition became critical, he having lost 40 ozs. of blood in all, and there was no sign of arrest of hæmorrhage. There was a considerable bulging of the left side of the pharynx, marked dyspnoea, and aphonia. At a consultation between Dr. Mahomed and Mr. Pepper it was decided to ligature the left common carotid artery, as it was thought dangerous to cut into the post-pharyngeal abscess. The patient was put under chloroform, and the artery tied by Mr. Pepper at the upper border of the omo-hyoid muscle, considerable difficulty being caused by the greatly distended state of the veins; carbolic catgut was used, and the operation per-

formed antiseptically. For a time respiration threatened to fail, but he rallied completely in three or four hours. Soon after the operation he brought up 6 ozs. of pus, and there was a corresponding diminution of the swelling. The temperature at once became normal, and the wound healed readily. April 7th.—Numbness of skin corresponding to distribution of superficial cervical nerve. Aphonia only partially recovered from. Fixation of left vocal cord. General health good.

Remarks by Dr. Mahomed.—Examination of the throat at the end of March showed that swelling and puckering of the mucous membrane at the entrance to the larynx were still present, both cords were normal in appearance, the right moving freely, but the left was fixed in a position of partial abduction. Secondary sore throat after scarlatina is not uncommon; it has occurred in 57 out of the 3,957 cases treated at the Fever Hospital during the last 10 years; it resembles the condition of the throat seen in the primary attack, but has never proved fatal in our cases; its occurrence depends upon the concentration of the poison, being more frequent when the wards are overcrowded or badly ventilated; they are, I believe, modified second attacks of the disease. Complete second attacks (with rash, sore throat, and fever) have occurred in 29 cases out of the 3,957; all recovered, except one, who died from other complications; these second attacks also depend upon concentration of the poison. Hæmorrhage from the throat is a rare but most dangerous complication, and may occur during the primary or secondary throat affection. It results either from sloughing of soft palate or (as in this case) from opening of a vessel into an abscess cavity. There have been 6 cases at the Fever Hospital during the last 10 years, and all the severe ones, with the exception of the present, have been fatal. The ligature of the artery appeared to exert a very beneficial influence over the inflammatory action, for it recovered most rapidly and completely.

Mr. HOWARD MARSH said that every hospital surgeon would be familiar with instances of large arteries opened into through ulceration of their walls. At St. Bartholomew's Hospital recently a man was admitted with a large psoas abscess associated with diseased lumbar vertebra. Post-mortem examination of the case showed that the aorta had given way into the abscess cavity. In another patient, Mr. Morratt Baker tied the common iliac for hæmorrhage into a gluteal abscess which had been opened. In a further case of ischio-rectal abscess, bleeding freely occurred when it was opened, from the internal pudic artery, but was overcome by compression. An example of bleeding maintained through the collateral circulation after tying the common carotid was cited, and the importance of determining the extent to which this might be anticipated insisted on. In a case at St. George's Hospital, that of a child who had fallen on a skewer which penetrated the neck, ligature of the carotid was performed and recovery ensued; but the operation gave rise to a discussion respecting its surgical justification. Mr. Marsh concluded by commenting on the great difficulties presented by all such cases.

Dr. DYCE DUCKWORTH defended the application of the ligature.

Mr. HARRISON CRIPPS questioned the propriety of tying the common carotid artery in such cases, and cited the results obtained from a study of 50 cases in which the operation had been performed. A mortality of 56 per cent. was recorded, and Mr. Cripps thought the dangers to be overcome were imperfectly appreciated, especially since a large proportion (30 per cent.) of the fatalities were attributable to brain complications, while in another 30 per cent. the operation was from the first useless. Even as a final resource, however, the operation was not justified, the external carotid alone offering a suitable site for applying the ligature. After tying it the circulation of the brain remained unimpeded, while collateral sources would suffice for the necessary nutrition of surrounding parts; and, moreover, it was extremely rare to find any branch of the internal carotid affected, some branch of the external being almost invariably implicated; and consequently the better surgical proceeding would be to ligature that vessel rather than the common trunk. In 30 examples of this proceeding only one instance of secondary hæmorrhage occurred, and the difficulty of finding the vessel should be no insuperable obstacle in the way of the operation. He could not help thinking

the wrong vessel had been tied in the case recorded, not withstanding the success attending it.

Mr. GODLEE narrated a case of psoas abscess due to disease of the last dorsal vertebra. Communicating with it were two sinuses, by inserting the fingers in which it was possible to feel the common iliac artery, and this vessel on subsequent post-mortem examination was found to have undergone ulceration.

Mr. BLAKE mentioned that in a patient in St. Thomas's hospital, after the common carotid had been ligatured, secondary hæmorrhage occurred from the internal carotid, which was found to have undergone sloughing.

Mr. BARKER inquired whether Mr. Pepper had been able to find any bleeding points?

The PRESIDENT observed that it was universally understood to be better to apply hæmostatic agents to bleeding points when discoverable rather than to arterial trunks; but in the case in question this course had not been possible. The branch from which the hæmorrhage arose was probably, but not certainly, small. He had noticed the power possessed, under certain circumstances, by blood clots, to maintain a hæmorrhage by the tension they induced, and in such cases perfect drainage might be depended on to reduce the bleeding. Mr. Cripps' suggestion to tie the external carotid was an important one. In reference to Mr. Marsh's narratives, Mr. Lister remarked that it was rare for an artery to open into an abscess before the latter had been opened externally, but the existence of such cases had now been placed beyond doubt.

Mr. PEPPER said the course he pursued was determined on after careful consideration and consultation, and notwithstanding Mr. Cripps' warning, he still preferred to ligature the common carotid before the external. The suppuration would be somewhere in the neighbourhood of the tonsil, and the ascending pharyngeal artery was most commonly affected, and as this artery arose, as a rule, from the bifurcation of the common carotid, ligature of the external branch would be useless for the purpose of controlling hæmorrhage from it. Moreover, had he followed the plan recommended by Mr. Cripps in his own case, he would have penetrated the sloughing cavity. The amount of blood lost, 40 ounces, in this case, showed that a large vessel had been opened. No bleeding point was visible, and the hæmorrhage was much more likely to have arisen from a vessel than from granulations, as suggested by Mr. Lister.

Dr. MAHOMED hinted at the greater frequency with which ulcerating arteries were encountered in surgical, as compared with medical practice, and proceeded to warn surgeons against committing the error of opening into fluctuating tumours under the impression that they were collections of pus; and he instanced a case of splenic leucæmia in which an apparent gluteal abscess when cut into proved to be a hæmorrhagic mass, the loss of blood occasioned being with much difficulty controlled.

Dr. RADCLIFFE CROCKER showed the ova and embryos of Bilharzia hæmatobia, and related

A CASE OF HÆMATURIA PRODUCED BY THAT PARASITE, which came under the care of Dr. George Bird at the beginning of the year. The patient was a boy at school, æt. 13, and was born in the Orange Free State, but appeared to have caught the disease in Natal, where he passed blood both by the urethra and bowel, and had been treated for dysentery. A few months after his arrival in England hæmaturia recurred in considerable quantity and produced so much dysuria as to necessitate the use of the catheter, and a small clot of blood which clung to the eye of the instrument having been examined by Dr. Crocker, the characteristic ova of Bilharzia hæmatobia were discovered. All troublesome symptoms soon disappeared, and with the exception of slight æmæmia, the boy seemed to be in good health; nevertheless the parasites are still present, and ova, and a little blood, were found in all three specimens of urine passed at different times in the day on October 4th. The spine on the ovum was always terminal, as is usual in those discharged from the veins of the bladder, and the head of the embryo showed no special preference for the spine end of the ovum. As the disease usually gets well spontaneously after puberty, no local treatment for the destruction of the parent Distoma had been employed. In blood taken at night from the finger no filariæ were discovered.

Mr. PEPPER asked how the parasite could be killed under the circumstances?

Dr. CROCKER replied that the accessibility of the parasite in the bladder would suffice to explain the reason.

Department of Lunacy.

SUPERANNUATION ALLOWANCES IN ENGLISH LUNATIC ASYLUMS.

At the Gloucestershire Quarter Sessions, held a few days since, considerable opposition was raised to a recommendation of the Visiting Justices of the County Lunatic Asylum, that a retiring pension of £550 per annum should be granted to Mr. Toller, the Medical Superintendent of that institution, on his retiring from office on account of ill-health. The intimation that this proposal would be made, which had been published in the advertisement of the business of the Sessions, had led to discussion at the meetings of a number of boards of guardians in the county, and memorials deprecating the amount of the pension proposed were presented at the Sessions from six large and important unions. The general tenour of the memorials, and of the remarks of the speakers who supported them, was to the effect that Mr. Toller ought to have been able to make ample provision for his own old age and for his family out of the emoluments of his office, which were calculated to have amounted latterly to £1,200 per annum, and that it was unreasonable to grant to any public official who was only fifty-nine years of age so large a pension as that named. No doubt some ungenerous hints were thrown out that Mr. Toller's management of the County Asylum had not been so successful as to justify a liberal superannuation, and that he had resigned in order to avoid dismissal, but such insinuations, which ought never to have been made in view of the fact that the pension is recommended by the Committee of Visitors of the Asylum, a body of gentlemen who have supervised Mr. Toller throughout his official career, were effectually disposed of by Dr. Ancrum, one of the Visiting Justices, who distinctly stated that an indisposition against which he had bravely contended, but which had finally overcome him, was the cause of Mr. Toller's retirement, and the sole ground of objection to the pension which therefore remained was that it was excessive in amount. But an equally valid objection to it, nay, a much more valid objection, would have been that it was deficient in amount, and much smaller than Mr. Toller might have reasonably expected that it would have been, for it ought to be borne in mind that Mr. Toller accepted the office of Medical Superintendent of the Gloucester County Asylum twenty years ago on the faith of expectations held out to him by an Act of Parliament that he would when disabled receive an ample pension than that now proposed, and that he has lived and served all these years in the same anticipation. By the 16 & 17 Vict. c. 97, sec. 57, and 25 & 26 Vict. c. 3, sec. 12, it is provided that it shall be lawful for a Committee of Visitors of any Asylum, if in their discretion they see fit, to grant, with the sanction of Quarter Sessions, to any medical superintendent who is fifty years of age, and has served for fifteen years, an annuity by way of superannuation not exceeding two-thirds of the salary payable at the time of his retirement, and of the lodgings, rations, or other allowances enjoyed by him. It would therefore have been competent to the Committee of Visitors of the Gloucester County Asylum to have recommended Mr. Toller for a pension of £800 per annum, instead of £550, an amount which they arrived at by calculating what he would have been entitled to had he been in the Civil Service of the country. But it was obviously the intention of the Legislature that Asylum

medical officers should be dealt with on a more liberal scale than ordinary civil servants, for in the Report of the Select Committee of the House of Commons of 1860, on which the enactment now in force and regulating pensions is founded, it is pointed out that the duties of lunatic asylum officers are of a peculiar character; that painful consequences result from intercourse with the various classes of lunatics when prolonged for many years; and that generous consideration in the matter of superannuation allowances ought therefore to be shown to all who undertake such distressing and hazardous duties. On a reasonable interpretation of the sections of the Acts of Parliament which we have quoted, and in view of the manner in which the provisions of these sections have been carried out in other counties, Mr. Toller might have looked forward to a larger allowance than is now proposed for him, when he is by reason of infirmity incapable of discharging any longer the onerous duty of his office, and it is to be hoped that the grumbling of a few guardians accustomed to dole out relief to paupers will not be allowed to interfere with the fair and honourable treatment of a professional man who has for twenty years filled an arduous and responsible post, and is now incapacitated for further work. The question of Mr. Toller's pension was allowed to stand over until the Easter Sessions, on the understanding that it would be reconsidered by the Committee of Visitors in the meantime. We confidently anticipate, however, that the Committee, having regard to the equity of the case and the interests of the institution committed to their charge, will adhere to their original recommendation and sanction no reduction of the moderate pension which they have already proposed. Should it be proclaimed that no retiring pensions, or only very meagre and insufficient ones, are to be granted in the Gloucester County Asylum, then a very rapid deterioration may be predicted in the character of the officers of that establishment, unless the salaries of the staff be increased in such a way as to compensate for the loss of all prospect of superannuation allowances. But this would be an expensive process for the country, for it ought not to require demonstration that moderate salaries with the prospect of a pension are more economical than large salaries and no such prospect. If the Gloucester County Asylum is to be well and economically managed it must have able and contented officers, and the way to secure these is certainly not to yield to popular clamour, and break faith, as it were, with one who has broken down in the service.

Special.

MORE ABOUT "TYPHOID" FEVER IN INDIA.

THE newspapers received from India give some information with regard to further inquiry now taking place into the causes of enteric (typhoid) fever at certain stations occupied by British troops in the Bombay Presidency. According to the accounts given of that inquiry, "there was a good deal of controversy as to the causes of the fever, and still more as to its precise character. It was a matter in dispute amongst medical authorities whether the fever was enteric (typhoid) or simply remittent. A good deal turned upon this question of diagnosis. Typhoid fever is generally considered to result from defective sewers and drains. The sources of remittent fever are more occult. The importance of establishing the exact nature of the fever is, therefore, self-evident." An inquiry is accordingly being made "as to the character of the fever and its supposed causes." We further learn that "post-mortem examinations have, in almost every instance, conclusively established that presumed remittent fever was really

typhoid, and for some time back the bills of mortality at the European Hospital at Bombay show cases of typhoid, and none of remittent, fever."

Taking the remarks extracted as above, there are certain points to which it seems well to direct attention. For example, is it not the case that the controversy alluded to in regard to the causes and character of the particular form of fever in question has arisen from the want, in the first instance, of a well-defined standpoint from which the affection was to be considered, alike by those who assigned its manifestations to climatic and other local conditions acting upon foreigners of particular ages, diathesis, and habits, and those who considered the disease to be in its nature specific, and due to one set of causes only, these causes affecting the body from without? What is the precise difference between "a simply remittent fever," in which a typhoid condition occurs, and "specific" typhoid, with remittent exacerbations? At the great majority of Indian stations neither drains nor sewers exist, nor is the condition of the locality such that they could be established even were they otherwise desirable. Yet at these stations particular types of fever prevail, according to season; the general form of the disease modified in one year as compared with another, the symptoms *sthenic* in the more robust and plethoric, *asthenic*, low, or *typhoid* in the physically weak; in the one class attended by cerebral, pulmonic, or hepatic complication; in the other, and in the young, by enteric complication. Would it, therefore, be appropriate to designate those of the one set as cases of the "cerebral," "pulmonic," or "hepatic" fever on the same principle that the latter is called "enteric"? Inasmuch as sewers and drains exist in places which for years remain free from "enteric" fever, and again, after the locality has been swept over by an epidemic. If the disease still remain while the population continues perfectly healthy, is not the conclusion evident that neither drains nor sewers are by themselves capable of producing in men near them the particular disease here alluded to? Was not the character of fever well and practically appreciated by medical officers in former days? Is it, or is it not, the case that a particular theory is constrained so as to force it to apply to conditions in India to which, as a matter of fact, it is not naturally suited or suitable? If post-mortem appearances are the same in "typhoid" and in "remittent" fever, wherein lies the difference between the absolute nature of the disease thus differently named? The actual *result* of morbid action being alike in both, the mere application of a name does not destroy that identity. When, therefore, the papers record the circumstance that bills of mortality show cases of typhoid and none of remittent fever, the question naturally occurs,—Inasmuch as prior to the introduction of the specific name "typhoid" the nature of the prevailing form of fever was well indicated and understood from the term "remittent" as applied to it, so now does not the same old form prevail precisely as in bygone times, but that, with changing nomenclature, the disease itself unchanged, the name alone has given way to one more modern?

France.

[FROM OUR SPECIAL CORRESPONDENT.]

ARTIFICIAL NURSING.—At the last meeting of the Académie de Médecine a discussion arose upon artificial nursing and the respective qualities of the different kinds of milk proposed. M. Devilliers criticised the idea proposed of erecting a regular establishment, under the control of the town, where the

quality of the milk of different animals—cows, goats, asses, &c.—could be accurately tested, and where the pureness of the liquid could be guaranteed. He considered that if proper care were taken of the children, and that the mothers were intelligent enough to take heed to the advice of the doctor, many of the evils attendant on artificial nursing would disappear.

TREATMENT OF TETANUS.—At the Société de Chirurgie M. Berger opened the meeting with some observations on the treatment of tetanus, and cited a case which occurred in his own practice. A man received a gun-shot wound, carrying away half of the hand and smashing the wrist. As the radial side was intact, M. Berger thought to preserve the limb, and placed it in an apparatus. Towards the fifth day the patient had spasms, and on the eighth tetanus fully declared itself. The contractions were very violent and prolonged. Disarticulation of the elbow was immediately performed, and the patient was put under the chloral treatment, of which, through the mouth and in enemas, three drachms daily. Immediately the operation was performed the spasms diminished in intensity, and in a week all symptoms of tetanus disappeared. M. Berger believed that chloral alone is not sufficient to arrest traumatic tetanus, but combined with the amputation of the member it succeeds very well. M. Anger, replying, said he had five cases of tetanus last year; and recently a child was treated by him for the same affection, produced by a crushing of the little finger. Chloral by the rectum was given, and in large doses, but it did not prevent the child from succumbing. M. Despres attributed the production of tetanus to the effect of cold air, and especially damp air. When he was at Sedan in 1870 he had a good number of wounded attacked with tetanus; but afterwards he served with the Armée de la Loire, and although the cold was much more intense, he had no case of this disease, although he attended a great many wounded.

TREATMENT OF FISTULA OF THE RECTUM BY THE ELASTIC LIGATURE.—M. Championnière read a communication made by a *confrère* at Marseilles on the treatment of fistula of the rectum by the elastic ligature, in which the author endeavoured to show that the elastic ligature was exempt from all danger, even in the gravest cases, and that it is a bloodless operation, never attended with inflammation, and causes no pain, permitting the patients to go about as usual the same day even of the operation. M. Championnière, although not so sanguine as to the results attributed by his learned colleague, declared himself ready to recognise that the elastic ligature did possess some very real advantages. M. Vernueil, on the contrary, opposed formally this method of treating fistulae, save in very small fistulae, where anything else would succeed as well. He has been in the habit of employing the thermo-cautery, and it has never disappointed him. M. Marc Sée used the ligature in a great number of cases, and although it could not be said that it was applicable to all kinds of fistulae, yet he considered it had an advantage over the thermo-cautery in that it could be applied during the time the patient was being examined. He also considered it preferable to the *écraseur*. M. Desprès could not understand why the *écraseur* should be rejected. He used the bistoury in 240 cases, and never had a case of hæmorrhage.

WHOOPIING-COUGH AS A CATARRHAL AFFECTION OF THE EPIGLOTTIS.—Dr. Bouchut, of the Children's Hospital, regards whooping-cough as a catarrhal affection of the epiglottis, and directs his treatment accordingly to that part when the disease is fully declared. As one of the

most important symptoms, besides the cough, he gives the presence of a little yellowish vesicle, formed by the elevated and thickened epidermis, which by its rupture gives place to an ulcer which persists as long as the malady. This ulcer is to be found near the frenum linguae. For treatment he canterises every day the pharynx and the epiglottis with a grain solution of nitrate of silver, while he orders an emetic—generally hippo twice a week, and ten to twenty grains of chloral in a mixture daily, or powder of oxide of zinc, twenty to thirty grains in the twenty-four hours.

Small Announcements of Practices, Assistances, Vacancies, Books, &c., of seven lines or under, 4s. per insertion; 6d. per line beyond.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Eco. Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLIAMS and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 5½ dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, NOVEMBER 1, 1882.

TYPHOID EPIDEMICS.

As records of careful, painstaking inquiry, the reports submitted to the Local Government Board from time to time by various medical officers of health on the subject of outbreak of disease are instructive in the highest degree. We are, moreover, indebted to no inconsiderable extent to these reports for our present exactitude of knowledge respecting the natural history of many specific fevers, the ingenuity with which the causes leading to epidemics at different times have been sought for being one of the most important agencies for influencing universal knowledge of disease. In many instances, the indefatigable perseverance shown in ferreting out and following up a seeming clue to causation have led to most important discoveries; and so much do we now admittedly owe to this method of investigation, that it has obtained recognition as a legitimate—and even as the only reliable—mode of

searching after such details of information as shall effectively determine the etiological relations of particular outbreaks.

Two reports of this description have been recently issued, which exactly illustrate both the method and the value of the inquisitorial system of investigation in cases of infectious epidemics. One of these is by Dr. Parsons, and deals with an outbreak of typhoid fever at Clapham; the other, by Dr. Barry, is concerned with a similar epidemic at Bangor. In Dr. Parson's inquiry the starting point was taken at the milk supply, the significant fact being early apparent that all the affected houses drew their supply of milk from the same dairyman. The report then goes on to detail the direction of further observations, and affords an admirable example of the care and labour which are now bestowed on such works. From the dairy at Clapham the inquiry was extended to the farm in Devonshire, whence the milk sold by the suburban dealer was daily forwarded, and every circumstance connected with the administration of the farm implicated most minutely examined into. The result showed that in general arrangements and cleanliness these were fairly satisfactory, and offered no material danger for comment. The water supply, however, on one of the two farms concerned, was found, on analysis by Dr. Dupré, to be entirely unfitted for drinking or culinary purposes, but, notwithstanding, half the milk daily forwarded to London was placed in tin pails in a trough filled with this water to cool, and by pumping further supplies in during the time the milk remained, it was more than possible that the latter should be occasionally contaminated. Moreover, cases of fever had occurred in the village of Musbury, where the farm referred to is situated, as lately as March last, and the conformation of the ground admits the percolation of sewage from the dwellings of the villagers to the farm water-supply, only 150 yards distant.

This array of facts, when once collected and compared, is amply sufficient to offer an explanation of the occurrence of a typhoid epidemic among the customers of the Clapham milk purveyor; but one other circumstance, at once curious and significant, deserves to be mentioned, both on account of its intrinsic importance in its bearing on the inquiry, and also because it exhibits the extreme carefulness with which this has been conducted. The dairyman referred to, in addition to the milk obtained from the Devonshire farms, sold also a certain smaller quantity each day, derived from cows kept in his own establishment, and for which, as "nursery" milk, a somewhat higher price was charged. In no single instance was there a case of fever reported among the families supplied with this milk alone; the affection was noticed chiefly among large consumers of the fluid, and especially in those cases where it seemed to have been imbibed *au naturel*.

Not so many years ago it would have been deemed an absurdity to suggest any such demonstration of connection between cause and effect as the narrative just outlined indicates; and it is by no means one of the least of the triumphs of modern medicine that the "craze," as some choose to term it, for preventive

measures is fast perfecting a science that will serve as a basis, at least, for future productive researches in the realms of etiology.

The Bangor outbreak was traceable to other causes than those conducing to the epidemic at Clapham; and in a lengthy report Dr. Barry exhaustively details the measures pursued with a view to tracking and counter-acting the influences at work. We cannot follow the history of these proceedings now; suffice it to say that the spread of the fever was incontestably shown to be due to drainage and other building defects, and that amelioration of the distress occasioned by it followed the adoption of appropriate prevention. The value of the report, apart from its scientific interest, is extremely great, for it offers an instance of the patient, consecutive inquiries of which so many are being constantly conducted at present in the interests of the public health.

It is with typhoid and scarlet fevers more than with any other zymotic that we have derived important information from the intelligent labours of health officers; and that still greater stores of information will be forthcoming as a result of their work we cannot venture to doubt. The scanty knowledge that guides all preventive measures needs to be improved and increased by every available means, and it is by such agencies as those alluded to above that the surest advance in this direction is to be anticipated.

PERSISTENT VOMITING OF PREGNANCY.

We are indebted to Dr. Rubinstein, of St. Petersburg, for a considerable amount of information concerning medical matters in Russia, and for his efforts generally to make known to the rest of the civilised world some of the excellent work done in the great empire of the north. A recent labour of this kind is a tolerably exhaustive notice of a monograph by Professor Horwitz, of St. Petersburg, on the "Persistent Vomiting of Pregnancy," which has lately appeared in the *Deutsche Medicinal Zeitung*. Professor Horwitz commences by finding fault with the name by which the affection in question is known—"persistent vomiting"—and says that it does not correspond to the pathological condition. He proposes to call it "pernicious vomiting of pregnancy" (*vomitus gravidarum perniciosus*), and understands by the term a condition that from the first exercises a grave influence upon its subject, gradually becomes worse, and finally passes into one in which the stomach rejects all nourishment, both fluid and solid, until either improvement or the death of the patient takes place. On consulting the records of his private practice, he found that 112 pregnant women (83 primiparæ and 29 multiparæ), out of a total of 186, suffered more or less from vomiting. His remarks on what may be called the ordinary vomiting of pregnancy call for no special notice. He carefully describes 12 cases of pernicious vomiting, the number including one case of extra-uterine pregnancy. He recognises two stages or periods. In the first stage, when the affection has existed but a moderate length of time and the appetite is still undisturbed, the vomit-

ing occurs several times a day, each time, however, immediately or soon after taking food. An early consequence of this is a certain degree of anorexia, with possibly a craving for indigestible articles of food. Occasionally, more or less thirst is present, but more frequently a troublesome pyalism; diarrhoea is rarely observed. In the majority of cases a peculiar mental disposition is observable, even when the loss of strength is not great. Many patients complain of a disagreeable smell, either of things about them or from their own persons (hyperosmia)—a symptom of grave prognostic significance. A similar hyperosmia has often been noticed by Horwitz in pregnant women, and in diseases of females; whilst other pregnant women, on the other hand, have a great fancy for certain odours. In the second stage of the disease the attacks of vomiting are more frequent, and they come on without the previous reception of food. They are the more burdensome from the fact that the stomach is empty. The ejected contents of the stomach consist of mucus, mostly of a greenish colour, not unfrequently with blood intermixed. Loss of flesh and strength soon follows the exertions made in vomiting, and from hunger and loss of sleep. A tormenting thirst is now present, with a dread of both food and drink. Constipation comes on (though Rosenthal is of opinion that this is not so). The urine is diminished in quantity, and contains albumen. Symptoms of fever are not observed in the first period; later, however, an inconsiderable increase of temperature manifests itself irregularly, whilst often the temperature is below the normal. The pulse, on the other hand, changes very rapidly, becoming more frequent—110 to 120—the pulse wave being small and compressible, and easily changing its character. After vomiting it becomes fuller. The consciousness remains unaffected, notwithstanding the universal weakness. Two or three days before death, however, a peaceful delirium, coming on at intervals, makes its appearance. All these clinical expressions may be looked upon as consequences of the starvation.

With regard to etiology, Professor Horwitz looks upon the disease in question as peculiar especially to the richer classes. In support of this opinion, he adduces the fact that of the twelve cases observed by him only two were afforded by his clinique; and the further one, that during his twelve years' connection with the Marien-Gebärhaus not a single case was observed. Some of his other conclusions are as follows:—1. That primiparae are attacked more frequently than multiparae. 2. That in a number of cases, relatively small, however, the vomiting is a simple reflex action. 3. That in the majority of the cases the reflex vomiting is a potential pathological condition, a consequence of antecedent changes in the sexual organs, more especially of the uterus. 4. That displacements of the uterus have not the grave pathological importance claimed for them by some authors—Graily, Hewitt (*sic*) and others; that they only play a part in so far as they indicate certain pathological changes in the parenchyma of the uterus. 5. That these changes really centre themselves in inflammation of the womb; inflammation of the lower segment, especially of the

neck (H. Bennet), is not so important as inflammations of the body and fundus. (Most probably this explains the vomiting of extra-uterine pregnancy.) 7. That the hyperemesis comes on in some cases in connection with more or less deep pathological changes in the stomach or intestines. 8. That the greater the disturbance is in the digestive apparatus the more likely is the vomiting to take on the character of uncontrollable hyperemesis. The prognosis takes its form according to the duration of the vomiting and the stage of the pregnancy. Hyperemesis runs a chronic course; is not uncontrollable from the first, but develops this character later on, when it presents a condition grave indeed, and even fatal. The prognosis is worse the earlier in the pregnancy the vomiting sets in, and also in primiparae. The following are of unfavourable import from a prognostic point of view:—Steady diminution in the quantity of urine excreted; presence of albumen in the urine; progressive wasting; dry, black tongue; violent cephalalgia; increase in frequency, and diminution in strength in the pulse; and finally, apathy. Death takes place from marasmus or peritonitis. Cases, however, have been noted in which, notwithstanding the above train of appearances, recovery has taken place, but—after abortion. Horwitz observed two cases in which improvement set in after death of the foetus *in utero*, and looks upon these as exceedingly valuable indications of the line of treatment to be adopted when all other means have failed. The death-rate has not been ascertained with any degree of certainty. Joullan has given it at 44 per cent., but the difficulty of fixing absolutely the class of cases that ought to be taken to make up the returns renders all figures given as death-rates uncertain and delusive. Braun, Hausmann, and Ahlfeld consider the prognosis favourable. In seven out of the twelve cases observed by Professor Horwitz the pregnancy was not interrupted. Of this number three died. In five artificial abortion was induced, and of these two died. So that of the twelve cases observed five died. Our author's experience leads him to the following conclusion:—That uncontrollable vomiting is one of the gravest pathological conditions with which pregnancy can be complicated, and very frequently (in 44 per cent. of the cases) leads to a fatal termination. We may here mention the views of a still more recent writer—Privatdozent W. W. Sutugin, also a Russian. He considers the term "uncontrollable" a misnomer, as the affection is capable of cure, and proposes the name "excessive vomiting of pregnancy" in lieu thereof. The hyperemesis he looks upon as a reflex stomach neurosis, having its origin in the genitals. In the second stage the temperature in the cases observed by him was always below normal; in one, however, the temperature was raised, but this was due to peritonitis; and he considers that in Professor Horwitz's cases in which the temperature was raised, that the elevation was due to complications. The pulse was rapid and weak; the respiration accelerated. Constipation was most frequent. The urine was diminished in quantity, contained albumen, mucin, and even tube casts. He could not fix upon any pathological condition as the cause. Sutugin observed five cases: one died after

artificial abortion, and a second from hemiplegia, the result of embolism. This case was complicated by pelvi-peritonitis. Two cases recovered, under treatment mainly dietetic; and one, in which this treatment failed, recovered after artificial abortion. Although he considers the disease curable, his results do not differ greatly from those of Professor Horwitz.

Treatment.—The legion of drugs recommended is the best proof of their worthlessness—alkalies, alkaline waters, bismuth, laudanum, cerii oxalas, sinapisms, blisters, chloroform or ether spray over epigastrium and back, ice-pills, iodide of potassium, bromide of potassium, nitrate of silver, electricity, &c. Besides this, they can only be employed in the early stages of the affection. Prof. Horwitz recommends absolute rest in the horizontal posture, and in a darkened room, the diet to be nourishing and carefully regulated. Nutrient enemata are counselled under the following regulations:—1. One or two hours before their employment the colon should be washed out with warm water; 2. Only small quantities should be injected at once (about three ounces at a time); 3. Frequent repetitions of them should be avoided, in order that irritation may not be set up; 4. In case of great prostration, 2 to 3 spoonfuls of good wine (*Xeres* or port) should be added; 5. In those cases in which the enemata are not retained a few drops of tincture of opium should be added. He considers the "gynæcological" treatment as of great importance. Should there be inflammation, depletion will be useful. Scarification is recommended rather than leeches. Nitrate of silver to the portio vaginalis he does not consider very useful, and on this point he differs from Prof. C. Braun, of Vienna. Mayer's method of redression by means of laminaria he recommends. He has twice employed Copeman's method without effect. He looks upon artificial abortion as the only resort in some cases, and speaks of it as follows:—In a case of uncontrollable vomiting in which all means of treatment have been employed in vain, whilst the disease grows gradually worse and threatens the life of the patient, then the only "chance" of saving her is the interruption of the pregnancy—i.e., artificial abortion must be induced, and, indeed, naturally in view of the clinical symptoms, and of the height of the danger, the timelier this is done the more rational is the doing of it. Artificial abortion is thus carried out:—After preparation of the genital organs by carbolised injections and dilation of the cervix, he separates the ovum from the uterine walls by means of the uterine sound. He only ruptures the membranes, when the process of abortion is delayed. In eight cases in which he has practised this method he has never seen portions of the placenta retained, whilst the loss of blood has been but slight, in fact, less than in spontaneous abortion. Transfusion he looks upon as an open question.

CHANGES OF CLIMATE IN RELATION TO HEALTH.

By means of the rapid and frequent communication which now exists between this country and the East, officers and other persons whose duty, business, or plea-

sure leads to India or China, are able to revisit England at short intervals. Many persons take what they call "a run home" at intervals of two or three years. In doing so, transition of climate is sudden and great. There is the excitement, and very often discomfort, of travel; then the flurry of business or of pleasure during their necessarily brief stay in England; and then the return to their former station or settlement, too often fagged and distressed rather than set up by the changes they had undergone during the past few months. What is the result of all this upon health? There is much reason to believe that it is by no means beneficial, at least in a great number of instances, and that it frequently tends to permanent ill-health. Whatever be the explanation of the circumstance, the fact remains that in not a few instances men who had remained completely free from intermittent fever, liver, or other endemic disease, so long as they continued to reside in India or China (and the remark applies to the tropics), generally become attacked by one or other of such affections on, or shortly after, their return "home." There is also the additional fact, which is becoming more and more recognised, that in a good many instances men who return to their several positions in our Eastern possessions from short leave in England become attacked by illness, from which those who have continued at their posts, even through the trying periods of the year, remain free. In like manner, the instances are numerous in which short leave to hill stations in India is followed by similar results to those just mentioned, so that the pleasures attending a brief residence at those extremely favourite and most agreeable sanatoria are by no means free from risk to health of those who indulge in it from year to year. In former years, when the chief communication with the East was by long sea voyage round "the Cape," Anglo-Indians visited England at long intervals, and when they did return to their native country in impaired health, remained sufficiently long for their complete recovery. Now all this is changed. Men *rush*, as it were, home and out again almost as a matter of course; so it happens that their bodily system no sooner has begun to accommodate itself to the local conditions, climatic and others, to which they are exposed, than the sudden changes already alluded to are undergone, and with the result mentioned. The custom appears to be growing up among men engaged in business in China to visit England during the "slack" season of the year, returning for the "busy" time. The expenses attending the maintenance of an establishment at our Treaty Ports renders it more economical for them to leave their families at home, and return to them for two or three months each year, than to have them out at those places. But it is to be feared that in many instances the pecuniary saving by this arrangement is far more than counterbalanced by the risks and actual injury to health involved in it.

SIXTY-ONE new students have entered at the University of Durham College of Medicine for the present year, viz., thirty-one for the full curriculum, and thirty for part of it. The latter, with one or two exceptions, are candidates for the medical degrees of the Durham University, and have entered in accordance with the regulations requiring them to fulfil a year of residence here.

Notes on Current Topics.

The late Professor Balfour.

It is a striking testimony to the influence which the late Mr. Balfour, though a young man, exerted on all who were brought into relation with him that a meeting, convened for the purpose of raising a testimonial to him, should have been attended and addressed by the eminent leaders of British science, who assembled with that object at Cambridge recently. Among those present on the occasion were Professors Huxley, H. T. Smith, A. W. Williamson, Ray Lankester, A. M. Marshall, W. K. Parker, Moseley, and Newton; and the tone of the addresses delivered sufficiently indicated the personal interest taken in the movement, as well as the keen grief felt by these friends of the late Professor, while considering his merits on the scene of his frequent labours. Professor Newton especially recalled the loss each one had experienced, and with visible emotion dwelt, in touching and eloquent strains on the subject of their thoughts. Mr. Huxley, too, referred to Balfour and his work in a way that demonstrated the poignancy of his own affliction, and at the same time showed a lofty appreciation of the late Professor's powers and attainments. The result of the meeting was the establishment of a fund, the proceeds of which are to be applied—(1) to establish a studentship, the holder of which shall devote himself to original research in biology, especially animal morphology; (2) to further, by occasional grants of money, original research in the same subject. A sum of £5,000 is already available for these purposes, the family of the late Professor having contributed £3,000 to the fund. A further sum of £1,000 was left to Professor Michael Foster by Professor Balfour's will, and will be devoted to the purposes held in view in creating the fund; and a sum of over £1,000 was collected at and immediately after the recent meeting. The value of the new studentship will be £200 per annum, this sum being fixed to enable the holder to devote his whole time, unfettered, to the pursuit of original research.

The Medico-Chirurgical Society.

THE Royal Medico-Chirurgical Society has for some time past exhibited symptoms of decadence which have excited a feeling of concern among the well-wishers to this, the oldest, of the medical societies. Endeavours are now apparently being made in earnest by the executive of the Society to recover it from the position to which it has fast been drifting, and at the first meeting for the winter session, held last week, the President, Mr. John Marshall, F.R.S., announced certain changes as having been carried out. These include the abolition of that objectionable rule by which authors were prohibited from reading their own papers, the practice having been for these to be communicated to the meetings by the secretaries. It is reasonable to expect that the writer of a paper would feel himself the most proper person to read the manuscript, and we can well understand that the prevalence of so unpopular a practice at the Medico-Chirurgical Society has seriously influenced the supply of papers in the past. Another improvement is the decision to make complete reports of discussions which take place for publication

in the Society's "Transactions." This cannot fail to prove a valuable innovation, and is one that might advantageously be adopted by other societies also. It will certainly lend increased interest to the proceedings, and additional stimulus to speakers to put upon record the views to which they may give expression, and which are not unfrequently of value little inferior to that of the paper which evokes them. The Medico-Chirurgical is to be congratulated on the advance it has inaugurated, and it is to be hoped that success equivalent to its deserts will attend it under the brighter auspices attending its entry on a new year of work.

"Thanks."

A VOTE of thanks to the Forces which have taken part in the late war in Egypt has just been passed by both Houses of Parliament. It is no more than right that full acknowledgments of services performed by the members of those services should in this manner be publicly made. The fact that it is so is gratifying to those who are named or included in the vote, and no doubt encourages zeal on the part of the younger men in the several ranks specified, in the hope that they too may some day be similarly honoured. But let us examine the phraseology employed in connection with this vote of thanks. That of paragraph 3 runs thus: After the enumeration by name of particular officers to whom it was resolved "that the thanks of this House be given," it is added "and to the other officers and warrant officers of the Navy, Army, and Royal Marines, including Her Majesty's Indian Forces, both European and native," &c. Considering the importance of the medical branch of the service to the success of an army, and to the well being of individual members composing that army, we feel that it would have been a well-deserved compliment to that department to have included the name of its "chief" in Egypt in the list of those specially given. "Precedent," we know, has been quoted on a former occasion against this. But "precedents" have to be broken through, or established from time to time. So therefore we had hoped that a distinction, at all times looked upon by those who are most directly concerned as most invidious and unfair, would on this occasion have been done away with. Very far from this being so, we are astounded to find as we continue our perusal of the published reports on the occasion, that to all intents and purposes the medical department is with some others cut away altogether from the "Army, Navy, Royal Marines, and Indian Forces." Here are the words of the Prime Minister, as reported:—"I am bound to say that on this happy occasion we owe a debt of gratitude to the civil departments under the Admiralty and under the authorities of the War Office. Yet the thanks we owe to them are only second to those which we owe to the military and naval services." Therefore, clearly, the departments alluded to are indicated thus officially as not only "civil," but as not being part and parcel of "the military and naval services." It is well that our brethren, whom heretofore we considered to be in, and of the Army and Navy, should be aware of the light in which they are looked upon, at least by the proposers of the vote of thanks in question. Over and over again we have endeavoured to advocate the cause of medical officers who

devote themselves to the service of their country. We would express a hope that the committee which is about to meet at the War Office may be induced to see that justice as well as public interests demand that the position in the military hierarchy which is their proper right be accorded to these officers.

Preserving Dead Bodies.

SOME time ago it was announced that Dr. Tonnietti, of Verona, had discovered a liquid preparation by means of which animal bodies might be preserved in a state of freshness for practically unlimited periods. The early experiments in connection with the new invention have now been completed; the efficiency of the preservative has been abundantly proved, and we may anticipate that it will ere long be available for general use. So far, however, the composition of the fluid has been kept a secret, and it is as yet not announced whether it is to be converted into a commercial success or proffered for scientific utilisation. If we may accept the accounts to hand as accurate, there can be no question of the invaluable nature of the fluid, by means of which animal bodies may be preserved supple, fresh, and in all respects like those just recently dead for any required length of time. The fluid is injected from twenty-four to thirty-six hours *post mortem*, and does not in any way alter the structural character of the tissues, either to sight, touch, taste, or smell, so that it is regarded as offering an important means of preserving alimentary substances. For dissecting and other purposes, also, it offers advantages such as no preservative in use at the present time possesses, that is supposing all that is reported concerning it proves to be verified by experience. In any case, however, the promise of successful employment in biological experiments, &c., suffices to make the new fluid a subject of much interest to scientific inquirers.

Drugs for Paupers.

THE *Pharmaceutical Journal* says that the occasional bad quality of drugs offered in the drug market is notorious among those who have to buy them wholesale. This month, no less than one and a-half ton of ipecacuanha was put up for sale, which was so covered with mildew that very little else was to be seen except the contour of the root. The question which naturally occurs to those concerned is, what will become of all this? Will it be washed and offered for sale again, or will it be exported to India, where the drug is used as a sheet-anchor in dysentery, or will it find its way into the army and navy stores after it has been cleaned and "polished up equal to new?" The variable quality of the wine made from this drug indicates the probable correctness of the supposition that damaged drugs are not destroyed in this country, but actually enter into commerce. This is a matter into which Government should look. It would have nothing to lose and much to gain by the appointment of an inspector whose duty it would be to examine imported drugs and to condemn and see that those unfit for use are destroyed. It is a matter no less important than the inspection of food. At the present moment it is said that spent hops which have been used in brewing in this country are being dried and exported to the Continent.

Hypodermic Injection of Iodoform in Syphilis.

DR. ED. THOMANN, in Graz, has made a number of experiments to detect the value of hypodermic injections in syphilis, and gives a preliminary statement of the results gained, so far, in an article published in the *Centrbl. f. d. Med. Wissenschaften*.

He made use of a solution of 20 parts glycerine and 6 parts iodoform. He began with 0.30 iodoform and the dose increased to 0.75. He employed also a solution of 0.30 iodoform in 6 ctm. sweet almond oil. He took cases in whom, with decided induration, the inguinal gland had also commenced to enlarge greatly. After he had made 10 to 12 injections on different parts of the body, he observed, in all his cases, a gradual disappearance of all signs. He found the experiments of Binz and Högyes confirmed. They had made theirs on animals. The injections produced almost no pain, or very little only, and the local symptoms were very moderate and by no means as severe as those following injections of corrosive sublimate. None of his patients complained of these hypodermic injections of iodoform.

Within two hours the remedy could be demonstrated in the urine. No disturbance of the general health, no increase of temperature or of rapidity of pulse followed, and the breath did not have the odour of iodoform.

The Typhoid Epidemic in Paris.

THERE were two hundred and forty-four deaths in Paris last week from typhoid fever, against two hundred and fifty the previous week. The number of persons known to be suffering from this malady on Saturday last was two thousand one hundred and forty-five. The epidemic would, therefore, appear to be nearly stationary for the time, as both the number attacked and the deaths correspond very closely with the statistics of the previous week.

Poor-law Medical Elections in Ireland.

THE following report of an election which took place last week at Listowel is an appropriate illustration of the way in which medical officers are usually selected. We suppose we need hardly remind our readers that professional competency or fitness for public duty has nothing whatever to do with Irish Poor-law medical elections:—

The proceedings of the Listowel Board of Guardians today were marked by a scene of unusual uproar and confusion. There was a large meeting, and this was occasioned by the appointment of an apothecary to the workhouse and Listowel Dispensary, rendered vacant by the death of Dr. Roche. There were two local candidates—Messrs. P. J. Wolfe and John Francis M'Guire—and owing to the great influence possessed by each candidate among the guardians, a very tight contest was anticipated. With the members of the committee of management rested the appointment of the dispensary apothecary, while the board of guardians had the disposal of the appointment of workhouse apothecary; thus those two bodies, independent of each other, assembled at the same time and place to proceed with the two distinct appointments. This gave rise to a question of priority, some of the guardians insisting on proceeding with their share of the business, while several members of the Dispensary Committee seemed determined to go to business. There was much warm discussion and confusion. Ultimately, some

members of the committee retired to the clerk's office, and having formed a meeting, proceeded to the appointment of the apothecary. Meanwhile several members of the committee remained in the board-room with the other guardians, amongst them the hon. secretary to the Dispensary Committee, who remarked, as his brother members were retiring to the clerk's office, "Let them hold their meeting, but I doubt if they can go on without me, as I hold the applications and diplomas, which must be produced" (laughter). After a few minutes the members of the committee re-appeared in the board room in time to vote for Mr. Woulfe, who was being elected by a majority of 20 against 16. A strong protest was written by Mr. G. P. Brown, J.P., and signed by several other members of the Dispensary Committee, against what they called the illegal and irregular election which took place in the clerk's office, and a requisition was signed requesting the hon. secretary to call another meeting of the committee at an early day for the purpose of proceeding with a new appointment.

Resorption in the Stomach.

DR. TAPPEINER has communicated to the *Zeitsch. f. Biolog.*, the result of his experiments on dogs, &c., regarding the power of resorption exercised by the stomach. He put a ligature around the pylorus, and introduced through an œsophagus-tube solutions, the contents of which quantitatively and qualitatively were known. He found that of watery solutions of glucose, sulphate of sodium, taurin, peptone, and strychnia very little was resorbed.

But if he took alcoholic solutions, the result was quite a different one. Far more was absorbed than left in the stomach, and while, for instance, the effect of a watery solution of strychnia became only very gradually apparent, and in a mild degree, the same quantity of strychnia in an alcoholic solution, caused, within ten minutes, the death of the animal.

The effect was, however, not uniform, and he observed that the rapidity and the quantity in these absorption processes depended, to a great degree, upon the quantity of fluid previously in the stomach. With the pylorus closed, watery solutions of chloral had very little effect, while alcoholic solution caused sleep within a few minutes. Of the alcohol, always three-fourths was absorbed.

This gives us an indication for the diet of persons suffering from cancer of the pylorus, or of induration and narrowing of this orifice, due to other morbid lesions. The nutritive material should be given in alcoholic solutions, and very little at a time, so that there is never much fluid at any one time in the stomach, and, for that matter, very little solid material also. All medicines, in such cases, should be administered, dissolved in alcohol.

False Death Certificates.

ELIZA MORRISH, an elderly woman, described as a midwife, has been fined £5 and a guinea costs, under the Births and Deaths Registration Act, for unlawfully giving a false certificate of the death of a child. The child had lived nine days, and defendant gave a certificate that it was still-born. The defendant's respectability, and the fact that no charge had been brought against her during the eighteen years she had been a midwife, were urged on her behalf.

A Strike against a Doctor.

SEVERAL hundred colliers have gone out on strike in the Ogmore Valley district, as a protest against the medical nomination of the management. The men are resolved not to go on with work unless the proprietors appoint a medical man of their choice.

The Study of Histology.

AT the recent annual meeting of the Dublin College of Physicians, the third reading of an amendment of by-law was adopted, by which it was resolved, "That, in accordance with the recommendation of the Inspection Committee, which was approved by the College on March 31st, 1882, histology be one of the subjects of examination for the first professional examination." Dr. Purser, King's Professor of the Institutes of Medicine, was appointed Examiner in Histology.

The Royal College of Surgeons of England.

AT the first meeting of the Council of the Royal College of Surgeons for the present session, on the 19th ult., Mr. Thomas Bryant, Surgeon to Guy's Hospital, and a member of the Council, was elected a Member of the Court of Examiners, in the vacancy occasioned by the resignation of Mr. John Birkett; and Mr. John Cooper Forster, Vice-President of the College, was elected Mr. Birkett's successor on the Dental Board. Sir James Paget, Bart., was nominated "Bradshaw Lecturer"—a lectureship founded in memory of Dr. William Woods Bradshaw, a Fellow of the College, and sometime Mayor of Reading. No date is yet fixed for the delivery of the lecture, but it is understood that it will be given before the close of the year. At the same meeting of the Council, Dr. William Joseph Lunn, L.S.A., of Hull, elected a Fellow at a previous meeting of the Council, was admitted as such, his diploma of membership of the College bearing date May 14, 1838.

Locomotor Ataxy of Syphilitic Origin.

WHEN M. Vulpian asserted that almost one-half (40 per cent.) of the cases of locomotor ataxy were of syphilitic origin the proportion was considered to be much exaggerated; but since that period the researches and observations of M. Fournier have demonstrated that M. Vulpian's affirmation was correct, and that the proportion given was rather under than above the actual number of cases. According to M. Fournier, in almost all cases syphilis has a part in the production of locomotor ataxy, and he gives the following rules regarding the management of the case:—1st. Always seek for any manifestations of syphilis in cases of locomotor ataxy. 2nd. If such exist institute immediately prolonged and severe anti-syphilitic treatment. 3rd. Syphilis should be energetically treated from the *debut*, so as to prevent the occurrence of such serious accidents later on.

THE Abbeyleix Guardians have passed a resolution reducing the salaries of their medical officers of health, as they consider that the duties to be performed are too highly remunerated. The Local Government Board have refused to sanction the proposed reduction.

Sir Thomas Watson.

THE profession will learn with sincere regret that the veteran and beloved author of the most brilliant treatise on Medicine in our language is in a state of health to excite the most anxious feelings. Although ninety-one years of age, Sir Thomas Watson has enjoyed almost wonderful health, until a few days ago he was suddenly seized with a slight paralysis. He is being carefully and assiduously attended by Dr. Walters, of Reigate, and Dr. George Johnson, who are of opinion that arterial obstruction has been set up in the neighbourhood of the right corpus striatum.

Foreign Meat.

THE frozen meat trade, according to the correspondent of the *Times* in Victoria, seems to be gathering strength with each successive shipment. The *Chimborazo*, which has lately arrived in London, took 1,900 carcasses of sheep of large size and prime quality. They were frozen and packed with great care at the Maryburnong Company's works. At Sydney the same vessel shipped 2,700 carcasses of mutton, of equal quality, but smaller than those shipped here. The retail butchers in Melbourne must be making enormous profits, for while this frozen meat company are exporting at a profit on sales in London, at 6½d., per lb., after paying freight and expenses, we are paying 8d. per lb. for prime joints in Melbourne.

THE munificent legacy of £20,000 has been bequeathed to the Salop Infirmary by the late Mr. Henry Spence, merchant of Shrewsbury, who died on Oct. 18th.

At a meeting of the Royal College of Surgeons of Edinburgh, held on the 18th October, Professor William Turner was unanimously elected President for the ensuing year.

DR. FRANZ RUBINSTEIN, of St. Petersburg, the well-known contributor to the *Deutsche Med. Zeitung*, has been invited to accept the office of Physician to a gynaecological hospital at Warsaw.

WE hear that Sir Hardinge Giffard, Dr. Abrath's leading counsel in the Sunderland conspiracy case, will move for a new trial on the first day of term, and the case will then be removed to London in any future proceedings.

THE first meeting of the Council of the Parkes Museum of Hygiene was held in the newly-acquired premises on Saturday last, when H.R.H. Prince Leopold was elected to the Presidency, and Sir Joseph Fayrer and Professors Tyndall, and Huxley were elected Vice-Presidents of the institution.

THE prize of £150 offered by the German Empress to the writer of the best handbook of instructions to the German societies of the Red Cross, how to keep themselves in a state of preparation for emergencies, has been awarded to Dr. von Criegern-Thumitz, of Dresden, a member of the Saxon privy council.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Bombay 27, Madras 40; Paris 25; Geneva 14; Brussels 20; Amsterdam 21; Rotterdam 22; The Hague 24; Stockholm 20; Christiania 15; St. Petersburg 41; Berlin 25; Hamburg 19; Dresden 18, Breslau 28, Munich 25, Vienna 25, Prague 25, Trieste 22; Rome 21; Venice 20; New York 29, Brooklyn 24, Philadelphia 20, and Baltimore 29.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Bolton 13; Norwich 14; Nottingham 15; Bristol, Salford 16; Leicester, Edinburgh 17; Birmingham, Blackburn, Derby, Wolverhampton 18; London, Brighton, Bradford 19; Halifax, Sheffield 20; Plymouth, Leeds, Portsmouth 21; Dublin, Glasgow, Manchester, Hull 22; Newcastle-on-Tyne 23; Huddersfield, Liverpool, Oldham, Birkenhead 25; Cardiff 28; Preston 31; Sunderland 34.

THE annual death-rates per 1,000 in the large towns last week, from diseases of the zymotic class, were:—From scarlet fever, 1.3 in Sunderland, and 1.4 in Sheffield; from measles, 2.0 in Wolverhampton, and 5.7 in Sunderland; and from fever, 1.5 in Leeds and Blackburn 1.6 in Portsmouth and Liverpool, and 2.1 in Preston. The mortality from whooping-cough was generally below the average. The 47 deaths from diphtheria included 28 in London, 8 in Glasgow, 4 in Edinburgh, and but 7 in the other large towns, of which 2 occurred in Birmingham. Small-pox caused 3 deaths in London, 2 in Newcastle-upon-Tyne, and one in Manchester.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

OPENING OF THE SCOTCH SCHOOLS.—The opening of the various medical colleges last week took place with the customary formalities, and with the usual horse-play amongst the students. At the Introductory of Professor Chiene in the Edinburgh University, they were unusually demonstrative, for, not content with a prolonged outburst of cheering on his entrance, they insisted upon a running accompaniment to his address with repeated stanzas of "When Johnny comes marching Home." Professor Rutherford and Professor Greenfield also received very flattering demonstrations in the Physiological and Pathological Sections; as did also Professor Cleland for his "Defence of Vivisection" at Glasgow. Two of these addresses we give in our present issue, as they are of considerable interest; the rest we hope to refer to in our next.

JOHNSTONE.—FEVER EPIDEMIC.—The fever epidemic which has been prevalent in Johnstone for the past six weeks is still exciting considerable alarm, as there is some uncertainty as to whether the fever is even yet showing any signs of abatement. Dr. Taylor's published statement for last month showed the mortality from scarlet fever to have been 12, while up to the 20th of this month there are 19 cases of death from the same cause, which shows about double the mortality for the present month in proportion to time.

Many causes are assigned for the epidemic continuing to assert itself in spite of all the preventive measures which have been adopted by the authorities. It is said that the ventilators of the various drains in the district, which were meant to purify the drains, are all more or less choked up, thus preventing to a considerable extent the egress of the gases. Meanwhile, the Commissioners intend to adopt more stringent measures than heretofore, with a view to stamping out the disease, and it is said a meeting has been arranged between the Commissioners and the School Board to discuss the present position of the town in connection with the epidemic.

ABERDEEN UNIVERSITY.—The competition for the chair of Surgery at this University has been decided in favour of Dr. Alexander Ogston, vice Dr. Pirrie, resigned.

THE COUPAR FEVER EPIDEMIC.—Dr. William Whitelaw, in his weekly report to the Sanitary Committee, states that six fresh cases of fever have occurred during the week, and the severity of the epidemic is shown by the occurrence of four deaths.

FEVER EPIDEMIC AT KILBIRNIE.—Typhoid fever is epidemic at Kilbirnie, there being more than 30 cases. The disease has spread rapidly in the past few weeks, and several deaths have already occurred.

LEITH.—THE QUESTION OF FEVER ACCOMMODATION.—The directors of the Leith Hospital lately agreed to request an annual payment of £500 from the Town Council for treating fever patients. At present the Council contributes £100 a year to the funds of the hospital, on condition that such patients should be received into the hospital when fever is not epidemic. When it assumes the latter phase, the hospital belonging to the Local Authority in King Street is opened; but this building has seldom been required for the past few years, and consequently there is no staff attached to it. The Public Health Committee have considered the application, and, while willing to increase the amount of the donation from the town, could not see their way to recommend the sum asked for. It was also pointed out that if a tax were to be imposed upon the ratepayers to raise the sum demanded by the directors the subscriptions to the hospital might show a corresponding falling off.

A GLASGOW DOCTOR AND HIS PATIENT.—It is no doubt disagreeable to take legal proceedings for the recovery of medical fees, but unfortunately the contemptuous estimate in which medical services are held by so many is such that vindication of our calling often renders the step a duty. It is notorious that, compared with other professions, there is a sad want of *esprit de corps* in the medical, and that the public are only too glad to avail themselves of this want of corporate coherency. In the Paisley Sheriff Court, on the 25th ult., Sheriff Cowan gave judgment, with £1 11s. 6d. of expenses, in favour of Dr. Ross, of Dumbarton Road, Glasgow. It was contended, on behalf of defender, that the treatment adopted by pursuer was not proper treatment; but after hearing the counsel for both sides, and reviewing the evidence, his Lordship found the charge of malpractice and want of proper care and skill on the part of the pursuer utterly unfounded. All the evidence clearly established that the pursuer gave the patient the best care and skill that could be devised. A wholesome lesson might now be taught the public by a counter-action of Dr. Ross against his pseudo-patient for defamation of character.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 21st ult., the mortality in Edinburgh was 75, and the death-rate 17 per 1000. Sixteen deaths occurred under 1 year, and 16 over 60. Diseases of the chest accounted for 38,

and zymotic causes for 12 deaths, of which 3 were due to diphtheria and 8 to scarlatina, the intimations of these diseases being respectively 10 and 56.

THE EDINBURGH HEALTH SOCIETY.—This Society, which has already achieved for itself considerable reputation by the admirable series of health lectures delivered last winter under its auspices, has issued another programme of similar lectures for the ensuing session. The course includes ten lectures, commencing on November 18th; and the lectures, with the exception of two, are all by well-known local medical men on subjects pertaining to the health of the body, and the disorders incident to its more important members, in which the public may be expected to take some wholesome interest.

THE PRACTICAL CLASSES OF PHYSIOLOGY, PATHOLOGY, AND MATERIA MEDICA IN EDINBURGH UNIVERSITY.—No further action of a definite character has been intimated by the University authorities, says the *Scotsman*, in reference to the recommendation of the Faculty of Medicine, published in September of last year, to include the subjects of practical physiology, practical pathology, and practical *materia medica* among the subjects required to be attended by candidates for degrees in medicine. This recommendation was at the time accompanied by explanatory statements signed by Professor T. R. Fraser as Dean of the Medical Faculty. In these statements the proposals in regard to physiology and pathology were submitted together, whilst that relating to *materia medica* was dealt with separately. Against the proposed change, so far as regarded the teaching of *materia medica*, memorials were addressed to the University Court by the Royal Public, the New Town, the Edinburgh Medical Missionary, and the Edinburgh Provident Dispensaries, and by the Chemists and Druggists' Trade Association (Scottish Branch). These memorials were remitted to the Medical Faculty by the Senatus, and the Faculty, on 28th June last, gave in a statement in reply. To this statement, again, answers were subsequently drawn up and sent in to the University Court by the Edinburgh Medical Missionary Society's Dispensary and the Edinburgh Provident Dispensary, with a view to their consideration by the Court at its late meeting. Before the meeting, however, Mr. Christison, the secretary of the Court, wrote to the Dispensary representatives to the effect that further consideration of the proposal of the Faculty of Medicine in regard to the class of practical *materia medica* had been for the time delayed. By the Medical Faculty it was contended in their statements that the proposal to transfer the class of practical *materia medica* from the list of voluntary to that of compulsory classes was in no true sense to add a new class to those required for graduation, inasmuch as practical *materia medica*, in some shape, was already compulsory on all candidates for graduation in medicine. It was rather a proposal to ensure, in the simplest manner that suggested itself, that certain desirable conditions should in future be present in the extra-academical courses which candidates for graduation were permitted to attend in place of the University class of practical *materia medica*. It was also stated that the teaching of practical pharmacy in the dispensaries was not satisfactory. For the objecting dispensaries, on the other hand, it was contended that, whilst they were, if required, willing to apply for recognition as teachers of practical pharmacy, there was no good reason shown for the proposed change, and they asked that matters should be allowed to remain as they were, until such time at least as the Scottish Universities Executive Commission should have sat and considered the whole question of alterations in University procedure and education. The effect of the proposed change would be, in their view, seriously to cripple the resources of the dispensaries by depriving them

of the students' fees for these classes, and also seriously to affect their power to relieve the sick poor who came to them for advice and treatment. They further urged that the students who attended the systematic course of the Professor of *materia medica* were entitled to receive from him all the teaching they required except such as was better taught in the course of the work of a dispensary than it could be in a University class-room. In support of the superiority claimed for the dispensary teaching of practical pharmacy, the memorialists stated, amongst other things, that the following Licensing Boards had declined to accept the certificate granted for regular attendance at the University class of practical *materia medica*:—The Royal Colleges of Physicians and Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, the Royal College of Surgeons of England, the Royal College of Surgeons of Ireland, and the Apothecaries' Company of London. In reply to the answer of the Medical Faculty that students might attend either an academical or extra-academical class of *materia medica*, the memorialists objected that the change would practically curtail the liberty at present possessed by the student of taking extra-mural classes. Out of fifteen classes (not including practical pharmacy, out-door dispensary work, practical midwifery, and vaccination), the student must now attend eleven at least within the University. The proposed alterations, if adopted, would add three classes to the other fifteen, but only one to the classes which might be taken outside. This, the memorialists submitted, made it obvious that the existing proportion between intra-mural and extra-mural classes was not to be preserved, and that the small amount of liberty of choice which students at present possessed would be restricted.

OPENING OF THE NEW SCHOOL OF THE IRISH COLLEGE OF SURGEONS.

THE Medical Session of the College, and the School, the reconstruction of which has been just completed, was opened, on Monday last, in the presence of the President, Council, Examiners, and Professors of the College, and of numerous visitors, including the President of the College of Physicians, the Medical Commissioner of the Local Government Board, the principal Medical Officer for the Army in Ireland, and other heads of departments. An address was delivered by Dr. Jacob, Professor of Ophthalmic and Aural Surgery in the College, who took for his theme the past history of the College (now entering on its hundredth session), the New Scheme of Education and Examination, and the improvements in the College School. We hope to give an abstract of the address in our next issue.

The alterations in the College School are such as to make it almost perfect. The dissecting-rooms and preparation-rooms have been thoroughly reconstructed, and newly lighted, fitted, and heated; a bone-room, in which every bone is displayed, marked with all its anatomical points, in order to facilitate the study of osteology, and a handsome new physiological laboratory have been added to the School; reading-rooms and additional lavatories have been built, and the lecture-theatre improved. On the whole, the School, when completed, as it will be in a couple of weeks, will be one of the most perfect in the kingdom.

In the House of Commons on Monday, the Secretary for War denied that Surgeon-General Hanbury had demanded a court of inquiry into the charges made against the Army Medical Department in Egypt.

Medico-Legal Intelligence.

IMPORTANT DECISION TO POOR-LAW MEDICAL OFFICERS.

At the Cambridge County Court, on Friday last, the judge, Mr. Bagshawe, Q.C., gave his judgment in the case of *Grubb v. The Chesterton Board of Guardians*. The plaintiff, Mr. J. S. Grubb, resides at Waterbeach, Cambridgeshire, and is one of the medical officers of the union. He brought an action against the guardians for the recovery of £3 3s. 6d., being 3s. 6d. for the supply of a truss to a pauper named Brewer, and £3 for the setting of the leg of a pauper, an old woman named Pearson. As the old woman was a permanent pauper, and the case, in the opinion of the guardians, not an urgent one, the claim was resisted. The leg, it appeared, had been set temporarily by Mr. Bridger, surgeon, Cottenham, and was a case, it was said, for the hospital. His Honour dealt with the larger claim—£3, for treating the woman Pearson for a fractured leg. The pauper had a ticket for permanent relief, and while that ticket was running the woman broke her leg. This was at Cottenham, and the woman was temporarily attended to by Mr. Bridger. On her way in a cart to Landbeach, her home, they met Dr. Grubb. His Honour was satisfied that the woman was not intercepted on her way to the hospital. Dr. Grubb attended the woman and re-set the leg. He sent in his claim for such attendance, but it was suggested that he could not recover, as he did not get a further order as required. The terms of the existing order, being without qualification, he took to be sufficient. He relied upon Article 76 of the Consolidated Orders, which stated that upon the exhibition of a ticket such person was entitled to receive relief in sickness. He also quoted Article 206, defining the duties of medical officers, and amongst them, which stated that upon application made on behalf of the party to whom a ticket was given, the medical officer would be bound to supply, as if he had received an order from the guardians. In that there was not a word suggesting that the plaintiff was bound to get any further order. The guardians could not make the woman go to the hospital. It was not the duty of the medical officer to provide extra facilities. Article 177 of the General Consolidated Orders settled the point as to plaintiff's remuneration—namely, £3 for setting the leg. His Honour was at a loss to discover any reason why plaintiff should not be paid; and allowed the £3 and costs, the 3s. 6d. being abandoned.

Correspondence.

A MEDICAL VIEW OF MEDICAL MEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your rather acrimonious critique of the address I had the honour to deliver to the members of the North of Ireland Branch of the British Medical Association, and which was not circulated by me, as you assert, but by the Council of the Branch, you take me severely to task for my strictures on the medical profession in this country, more especially in Dublin.

I am glad you have thus honoured my paper with a reference in your widely read and influential journal, as it enables me to explain a passage in it which, I am very sorry to hear, has given offence to some of the leading members of the profession in Dublin. Such certainly was not my intention; no one could for a moment believe that I would willingly say anything to insult the name of Banks, my late father's oldest friend, and one from whom I have always received the greatest kindness; or Colles, the son of my father's much-loved tutor, or indeed any of the other gentlemen mentioned in your list, which might with advantage have been much extended by the addition of such other names as Bennett, M'Dowel, Corley, Fitzgerald, W. Stokes, &c. In the paragraph of my address to which you refer, I intended merely to direct the attention of my hearers to the absence in this country of an Irish living author of importance in any of the various branches of medical and surgical science. I know full well we have plenty of first-rate practitioners in these various branches of medical knowledge, but I repeat,

"Ireland at present is not represented by an authority of weight in our libraries," with the single exception of Atthill's admirable work on the diseases of women.

I think few will disagree with my remarks on the important questions of medical education and examination; anyone who has the opportunity, as I frequently have, of testing the clinical knowledge of recently-qualified students, must know the entire rottenness of their practical training. I have heard of young men who passed their final examinations, and did not know the difference between paronychia and onychia; I have frequently seen those who could not bandage a limb, apply the commonest splint, take a temperature, distinguish the character of an ulcer, write an ordinary prescription, or even know how to go properly about the examination of a sick or injured patient; and yet I am accused of *mala fides*, and a desire to injure the profession which I love, because, forsooth! I dare to draw attention to the absurdity of an examination system which annually lets loose crowds of untrained youths to ply their vocation upon the unfortunate public, until by practical experience—probably acquired by a considerable increase in the mortality of their district—they have learned for themselves what was denied them as students. I assert once again that, as medical education is conducted now-a-days, everything is done to exalt the theory without even a proper attempt being made to elevate into a higher grade the clinical knowledge and application of theory by a sound and well-understood system of practical instruction. The Irish College of Surgeons and other examining bodies, in this country and elsewhere, with the fear of Government before their eyes, have recently been engaged in framing elaborate rules for the education of their students, but it is labour lost, so long as they permit, as they unquestionably do at present, the grossest clinical ignorance to pass unchallenged from their halls. It is indeed time that the jealousies and divided interests of our nineteen licensing and competing colleges were put an end to by the establishment, in each division of the United Kingdom, of an independent examination board, under the control and in the pay of the Government, through whose portals alone access could be gained to the medical profession. It is only by such means, and the consequent elevation of the educational standard of the student, both on his entrance into and his exit from his professional studies, that the rush of badly-educated youths into our profession will be stopped, and the overcrowded condition of our ranks put an end to. Let us take a familiar example of the method now adopted in training our students. Let us grant, by way of argument, that they have every opportunity of attending hospital, which they have not—their time being so fully occupied with lectures, &c.—I assert that, in consequence of the large number of students, and the small number of really large, well-equipped, and supported hospitals, not ten per cent. of the young men attending these institutions ever obtain even a dressership, or have any chance afforded them of becoming practically acquainted with their business. What would be said of a carpenter, blacksmith, mason, &c., if they adopted this plan of instructing their apprentices. I fancy there would be very little use in a young blacksmith knowing all about the anatomy of a horse's hoof, or the microscopical appearances of its ligaments, &c., if he had never been taught practically to apply his knowledge during his apprenticeship; and yet in the medical profession, the apprentices endeavouring to master its intricate problems are almost entirely ignorant of the most elementary practical knowledge.

If any words of mine can strengthen, even in a small way, the hands and arguments of those who so urgently demand the intervention of the Government in our professional examinations, they will not have been spoken in vain, notwithstanding the strictures of the *Medical Press and Circular*.

You, Sir, have taken me severely to task for my remarks upon the want of education among medical men, and because I complained of their want of cohesion and *esprit de corps*. I certainly did refer in very plain terms to these, and many other questions touching our profession, but I had no intention of crying it down, or saying one word to injure the reputation of medical men generally in the eyes of the public; indeed, the editor of another medical journal considers I have taken far too hopeful a view of the present and future of our profession, which, in his opinion, is becoming so much overcrowded by the laxity of examination and

curriculum, and the scramble for the students' money of most of our nineteen competing colleges, that instead of improving, the tone, &c., of our profession is every day getting worse. This I do not for a moment believe; but if we desire to advance the profession of medicine to that position of influence and dignity to which its disinterested national services so justly entitle it, we must be prepared to look sternly in the face our own shortcomings and those of our colleges, and not adorn ourselves in peacocks' feathers (as you, Mr. Editor, seem so much inclined to do), and looking at ourselves as we strut before our pier-glasses, exclaim what fine fellows we are. I would be the last to wish to insult anyone; I stated so at the opening and close of my address.

I have, however, strong opinions, and as a young man, I am in the habit of expressing openly my convictions; surely, then, no one will think the worse of me if I ventured to state some truths which the numerous letters of approval I have received from all quarters of England, Ireland, and Scotland, amply demonstrate to have had, at any rate, some foundation.

I pass over without notice your other strictures, which I suppose were only intended as fringes to adorn a well-known sarcastic style of composition, merely remarking, in conclusion, that in "that seat of learning, Omagh," there resided, not many years ago, a provincial surgeon who was second to none in Dublin or elsewhere, and who has left behind him a name which is treasured still by many an old friend and companion in that ancient city.

Yours, &c.,

EDWARD THOMPSON, M.B.
Surgeon Tyrone County Infirmary, &c.

Omagh, Oct. 21st, 1882.

"IRISH ACADEMY OF MEDICINE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I will feel obliged if you will kindly insert the following extract from the *Dublin Quarterly Journal of Medicine* of August, 1851, in which I proposed the formation of an Irish Academy of Medicine. I am truly glad to see the project now take such practical form, and I will be happy to lend it all the aid in my power, should it be thought desirable to give it permanent form and legalised status under Royal Charter. I trust it may find a home with our scientific institutions in the new Central Buildings to be erected on the Leinster House premises.

Faithfully yours,

R. D. LYONS.

Oct. 29th, 1882.

"The establishment of an Irish Academy of Medicine has long and anxiously occupied our thoughts, and we feel convinced of the feasibility of such a project. The present constitution of our National Academy offers great facilities for the incorporation with it of scientific sections, precisely similar in all respects to the 'Academies des Sciences, Médecine,' &c., of the Institut de France. We need only in fact, transform our committees of 'science,' 'antiquities,' &c., into 'sections' (the term 'Academy' being restricted to the general body). Admission to the Academy at large, we suppose, must always, for cogent reasons, remain on its present footing; but the 'sections' could assume all the functions and dignities of the 'Academies'; and admission to them should only be allowed to the most tried merit, and from the general body of the Academy, by a rigorous system of election. We indulge hopes that such a scheme may be carried into execution before many years; and we make no doubt that an Irish Academy of Medicine, if wisely directed, would have the most happy influence on the progress of our science."—*Dublin Quarterly Journal of Medicine*, August, 1851, page 110.

Royal College of Surgeons of England.—The following candidates, having passed the required examination, received the Diploma in Dental Surgery at a meeting of the Board of Examiners on Wednesday, Oct. 25th—

Aiskand, John M'K., Exeter.
Albert, Henry Louis, London.
Andrew, James, Belfast.
Bate, Frederick William, London.
Cornelius, W. F., Teignmouth.
Edwards, Richard, Pontdolgoch.

Gould, John Horace, Exeter.
Hughes, Morgan, Redhill.
Kassak, Frank Hill, Douglas.
Boyston, Jonathan, Douglas.
Patterson, Wm. T., Kilmarnock.
Tester, Alfred Horace, Brighton.

Literature.

THE PREVENTION OF STRICTURE AND OF PROSTATIC OBSTRUCTION. (a)

This interesting little book is a republication of an article by Mr. Harrison, which originally appeared in the *Lancet* of May 15th, 1880, entitled "*The Prevention of Stricture*," coupled with an additional paper on "*The Prevention of Prostatic Obstruction*." The author energetically combats the view recently advanced by some surgeons that the presence of a gleet is necessarily due to a strictured urethra, instead of being, as most of us have hitherto believed, rather an indication of an inflammatory process antecedent to the formation of stricture, and consequently of a state generally curable by more simple means than the use of dilating urethrotomes, &c. Mr. Harrison also questions whether any injection, as used with the ordinary glass syringe, ever succeeds in reaching the deeper portion of the urethra, which is commonly the seat of the inflammation causing the gleet; and he therefore asserts that the failure of ordinary treatment by injections, &c., is due to the fact that the remedies are either insufficiently applied to the diseased tract, or do not reach it at all. In order to secure a complete and satisfactory medication of the diseased parts, he recommends a very simple apparatus, specially constructed for the purpose, which consists of an ordinary Higginson's syringe, with a vulcanised rubber catheter of suitable size and construction. The catheter is passed up, or near to the diseased part, and is then attached to the nozzle of the syringe, which is already filled with the injection. The author tells us that he has obtained the most satisfactory results by this means.

Whilst advocating this method of treatment for gleet, he lays stress on the importance of making a physical examination of the urethra after all attacks of gonorrhoea, with a view to finding out whether a stricture actually exists or not; but he omits to state what line of action should, in his opinion, be taken, when a slight but unmistakable stricture does exist. We think that Mr. Harrison has done good service by his denunciation of a reckless and improper use of cutting instruments in urethral surgery; but, at the same time, we think, he should have reminded his readers that, although his plan of treatment may prevent a stricture, it cannot be of any avail when once this disease has definitely appeared. With regard to the author's remarks on the prevention of prostatic obstruction, we have not much to say. The mechanical treatment principally recommended by him consists of the constant and regular use of the catheter, at least once a day from the earliest beginning of the symptoms. He believes that the constantly repeated pressure of the instrument so moulds the enlarging prostate that the channel, is, as it were, kept free and open. Whether this be so or not, the practice of frequent catheterisation is very generally recommended in our best text-books, with the object of removing the residual urine; and we cannot see any great difference between the author's treatment and that usually practised, unless it be that in the former case the instrument is used at a somewhat earlier period than in the latter. We might add that, in our opinion, something should have been also said as to the very great importance of cleanliness in the use of the catheter, as it not uncommonly happens that the patient's troubles are enormously aggravated by the use of unclean instruments.

Medical News.

Royal College of Physicians of London.—The following candidates, having passed the required examinations, were admitted Members on October 26th—

Bonham, Frederick Lucas (M.D. Lond.), Notting Hill, W.
Edwards, Edward Joshua (M.B. Lond.), 55 York Street, W.
Oliver, Thomas (M.D. Glasgow), Newcastle-on-Tyne.
Orxley, Alfred James Rice, M.B. Dub., Oxford and Camb. Club, S.W.

The following candidates, having passed the required examinations, were admitted Licentiates on October 26th—
Abrath, Gustav Adolph, (M.D. Heidelberg), Sanderland.

Dixon, Henry Charles, Portinacale Road, S.W.
Dun, Walter A., (M.D. Miami), 79 Queen Street, Chesham, E.C.
Howard, Robert J. B., (M.D. McGill), 103 Guildford Street, W.C.
Hull, Walter, Swallow Place, W.
John, David, Swansea.
Khan, Mohamed Ismail, 18 Montague Place, W.C.
Massey, Henry Massey, Peckham Road, S.E.
Myles, James Percival, St. Mathias Vicarage, Bristol.
Panioty, John Emanuel, 28 Green Street, W.
Penn, John Evans, 4 Cumberland Terrace, W.C.
Powell, John James, Jun., Heathlands, Weybridge.
Robinson, Frederick Gardner, Pendleton, Manchester.
Sinclair, John, Queen Adelaide's Dispensary, Bethnal Green, E.
Skipper, Edward, University Hospital, W.C.
Stead, Geoffrey, Birmingham.
Thane, Philip Thornton, 15 Montague Street, W.C.
Tripp, Charles Llewellyn Howard, Royal Free Hospital, W.C.
Williams, Edward Richard, St. Bartholomew's Hospital, E.C.
Wise, Charles Henry, Westminster Hospital, S.W.
Wohrntz, Ferdinand Broer Mathieu, 89 Albert Street, N.W.

Royal College of Surgeons in Ireland.—At the Examination in General Education held on the 18th and 20th of October, the following gentlemen were adjudged certificates of qualification, the names in the First and Second Classes being arranged in order of merit:—

First Class.—Alfred W. Douglas, Charles D. McCarthy, Frederick McDowell, Edward W. M. Adir, John B. Moore and Thomas J. Mulholland equal, Daniel Fogarty and Michael J. Geary equal, Edmund J. Jacob, Patrick J. Carey, Thomas E. Dunne and Michael Riordan equal; George H. Grace, Edward Hudson and Gerald C. Pelly equal, James Metcalf and William B. Swan equal.

Second Class.—Austin S. Clutterbuck, Henry A. Fullam, James McCabe, James K. Murray, Francis O. O'Donohoe and Patrick F. O'Hagan equal, Thomas W. D. Armstrong, William A. H. Egerton and Thomas Moriarty equal, Thomas W. D. Pownall and William L. Ross equal, Alfred Robinson, Patrick Callaghan, William P. McEvoy, Luke McGuinness and James Frant equal, Patrick D. Coen, Robert H. Cox, Collie E. Dick, John M. Hayes, William H. Litton, Frederick P. Handell, Cecil O. Pelly and Joseph P. Sexton equal, William Carey, John M. Clery, Thomas M. Frood, Joseph P. Mulligan and John Norton equal, Thomas Coghlan, Andrew A. Doyle, John J. Hall, John F. Nelly and Joseph O'Connor equal.

Unclassed.—Edward C. Brabson, George H. Brownrigg, John H. Browne, William Browne, Percy G. Carle, Augustus H. M. Cramer, George W. Dick, Samuel H. H. Douce, John Greally, Alexander J. Griffith, Holloway W. Hastings, Richard Hugo, James G. Kearney, William B. Kearney, John E. Kinsella, John Leaky, Florence McCroger, James H. Morgan, St. George R. Nunn, John W. O'Brien, Maurice O'Connell, Everard M. Power, Pierce H. Power, David Ross, William J. Scott, Alexander V. Shine, Charles F. Sizemith, Ernest W. Stoker and Thomas H. Wilson.

University of Edinburgh.—The following gentlemen have passed the first professional examination, October, 1882:—

William Anderson, William A. Anderson, Edmund Antrobus, John Bardgett, T. W. Barradough, George S. Baschet, Wm. J. Bell, Charles Bennett, Reginald Bowman, Joao Francisco Braga, J. D. Broadfoot, Harbit Brown, R. F. Burt, Ernest Kenneth Campbell, David Case, Ernest Jam's Chestham, Stephen Frazer Clark, Frank Gerard Clewov, Frederick William Collinson, Robert Swan Coulthard, James Cunningham, George Scott Davidson, Joseph Wm. Dawes, John Henry Deamer, Kenneth Mackinnon Douglas, David Somerville Doughty, J. J. Drinkwater, Walter Musgrave Eaton, Ahmed Fahmy, Peter Fraser, Edwin Sargood Fry (with distinction), John Garvie, William Gregory Gibson (with distinction), James Gray Glover, Robert Gordon, J. W. Grant, Alexander M. Gray, Allen Edward Lambton Gray, David Campbell Gray, David Middleton Greig, Thomas Howard Griffith, Joseph Griffiths, George Lovell Gulland, Charles Robert Haller, Joshua Jacobus Hoffman, Robert Wilberforce Inkster, Samuel Baker Jones, Robert Conwy Joyce, H. L. St. P. Keelan, Frederick Truby King (with distinction), Ernest Cory Kingdon, John Charles Lamont (with distinction), John Dickinson Leigh, Charles Lewis Lempiere, Charles James Lewis, Edward Linton, William G. Little, James Richardson Thom's Logan, A. L. B. Loubaer, Wilton Wood Russell Love, Donald Campbell Archibald M'Alum, Duncan M'Diarmid, J. R. M'Gavin, George Donald Macintosh, John M'Jarrow, Francis Wallace Mackenzie, Wm. Henry M'Lean, Robert MacLellan, John M'Donald MacLellan, Robert Charlie MacWatt, Daniel Groves Marshall, Charles G. Matthew, David Macleish Moir, David Morgan, Thomas Morris, Robert S. Morrison, Charles James Morton, John Kemp Murray, Andrew W. Nash, William Ramsey Nasmyth, F. A. Neal, John M'Donald Nicoll, Maurice Peterson, John Pirie, George Porter, Edward Thomas Pritchard, Trevor John Pritchard, Selwyn Hall Puckle, James Reid, Francis Mortimer Reynolds, J. B. Ridley, John Richards, Ernest Robertson, Ernest Theophilus Roberts, Frederick Charles Roberts, Hugh L. Roberts, Arthur MacLeod Ross, John Ross, D. Wilson Scotland, Gerard Affleck Scott, W. E. S. Scott, Harold Scurfield, Robert William Smeddie, George Purves Smith, John William Smith, George Laird Somerville, Gabriel H. Steyn, Robert Stewart, Robert Stirling, William George Sym, Charles C. Teacher, Caleb Terry, John Bolton Thackwell, William James Thomas, Francis Courtney Thorp, John William Travell, Ernest B. Turner, J. C. S. Vaughan, Quinton Macadam Wallace, John Warnock, Clarence Henry Waters, Adam D. Wilson.

Electricity as a Cardiac Stimulant.

A FACT of the greatest importance, practically—especially with reference to the treatment of threatening death by chloroform—has just been determined by Professor von Ziemssen. In investigating the effect of electricity upon the heart, he has discovered that the induced current has no influence whatever upon the frequency or force of the cardiac contractions, whilst the continuous or battery current most distinctly affects them. Many tracings of the movements of the heart under different conditions were first made, and a careful record was obtained of the effect of physical disturbance of the various parts of the cardiac surface. The influence of the different forms of electricity was then thoroughly investigated, cardiographic tracings being taken simultaneously. The most interesting fact determined was the complete failure of the faradic current to alter the action of the heart, or to disturb in any way its sensibility, whilst the direct battery current produced a marked effect.

Notices to Correspondents.

✂ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 25 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

PREMKIA—The compounds of salicin are almost universally employed now in the treatment of acute rheumatism, the objections maintained against it being held to contra-indicate its employment only in certain cases. It has undoubtedly been followed with excellent results in the majority of cases, but it is not possible to speak positively respecting the injurious influence it exercises over the heart. Its power to relieve pain and reduce temperature is both marked and incontrovertible.

MR. ROLANDSON.—You shall receive due intimation of the result.

DR. MANTLE.—Your opponent cannot justify his conduct by any appeal to medical etiquette. He has, apparently by intention, acted with utter disregard of all the rules supposed to govern the relations existing between members of the profession; and unless he responds to an application for restoration of the position he has usurped, you will be entitled to take immediate measures to remove him.

L. G. E.—The present state of the law forbids your making the attempt. By so doing you will become liable to prosecution by some one or other of the anti-knowledge associations which depend for support on the effects produced on ignorant people by their efforts to worry scientific investigators.

DR. K.—Received. Colour undetermined.

DR. J. R. (London) is thanked for the report, which he will find is referred to in another column.

E. S. R. (Kingston).—The best known institutions for the treatment of the class of disease referred to are:—Tower House Retreat, Westgate-on-Sea, and Melville House, Musselburgh, for gentlemen. For ladies there is St. Raphael's Home, Croydon; and there are several private licensed houses usually kept by medical men in which patients are received. If our correspondent desires it, these can be furnished him in a subsequent issue.

DR. HATTON.—The matter came under our notice as we were going to press; we shall refer to it in our next issue.

EGYPTUS.—Your letter opens up a wide field for discussion in which opinions are very divergent. On reference to the daily papers you will see the subject is engaging the attention of Parliament, and that a committee of investigation has been appointed. Meanwhile, your letter shall be fully considered, and, if possible, insertion given thereto in our next.

DR. H. D. (Bournemouth) will please receive our best thanks for the information conveyed in his note.

MR. W. R.—MR. of Part II. to hand, with thanks.

A RESIDENT IN THE NEIGHBOURHOOD.—A fresh writ has been issued against the manager; whether this will succeed remains to be proven. The authorities have certainly a most unenviable and difficult task before them.

THE SANITATION OF THE FUTURE.—The *New York Medical Record* is responsible for the following description of the sea-side sanitary hotel of the future:—"Anxious Guest to the Hall Boy: 'Boy, where are the water-closets?' 'Haven't got any, sir; they breeds fever. Boat goes down the harbour every morning—ladies at nine, gentlemen at ten.' 'Well, is dinner ready?' 'No, sir, we always carbolise the dining-room before meals. Now they are spraying the waiters, sir.'"

(Impatiently), 'Well, where is your food-water?' 'Don't have drinking-water now, sir; 'taint healthy. Yonder's our Labarraque mixture, flavoured to taste. Have a glass, sir!' Guest retires and takes a thymolised julep."

MEETINGS OF THE SOCIETIES.

EPIDEMIOLOGICAL SOCIETY OF SOCIETY.—This (Wednesday) evening, at 8 o'clock, Dr. Norman Chavers, "On the Sanitary Defects of the Site of London and its Suburbs."

OBSTETRICAL SOCIETY OF LONDON.—This (Wednesday) evening, at 8 o'clock, Specimens will be shown by Mr. Alban Doran and others.—Dr. Champneys, "On a Description of a Kyphotic Pelvis, with remarks on Brelsky's Description."—Dr. Matthews Duncan, "On Puerperal Diabetes."—Dr. Chahbazian, "On the Treatment of Post-partum Hemorrhage by Subcutaneous Injection of Ergotinine."

HARVEIAN SOCIETY OF LONDON.—Thursday, Nov. 2nd, at 8.30 p.m., Mr. Malcolm Morris, "On Chronic Ringworm."—Dr. Broadbent, "On some Points relating to the Sounds of the Heart."

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—Monday, Nov. 6th, at 8 p.m., Dr. Alfred Carpenter, "On Considerations of some of the Causes which give rise to Dental Decay."—Casual communications from Messrs. Charles Tomes, Coleman, and Sewill.

ROYAL INSTITUTION.—Monday, Nov. 6th, at 5 p.m., General Monthly Meeting.

Vacancies.

Dundalk Union, Carlingford Dispensary.—Medical Officer. Salary, £100, and 25s as Sanitary Officer. Election, Nov. 4th.
Magherafelt Union, Bellaghy Dispensary.—Medical Officer. Salary, £120, and £15 as Medical Officer of Health. Election, Nov. 6th.
Ongar Union, Essex.—Medical Officer and Public Vaccinator. Salary, £50, with the usual extras. Applications to be sent to the Clerk not later than Nov. 6th.
Victoria Hospital for Children, Queen's Road, Chelsea.—House Surgeon. Salary, £50, with board and lodging. Applications to be sent to the Secretary on or before Nov. 7th.

Appointments.

APPLEFORD, S. H., M.R.C.S., a House Physician at the London Hospital.
BARLOW, T. C., L.R.C.P. Ed., Medical Officer to the Third District of the Hackney Union.
CLENDINEN, J. G., L.R.C.S.I., Medical Officer of Health for the Lower Sedgley Urban Sanitary District.
CROSS, F. E., M.B. Lond., F.R.C.S. Eng., Honorary Surgeon to the Bristol Eye Hospital.
FERRIS, J. S., M.B., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Denham District of the Eton Union.
GAILL, A. K., M.R.C.S., Assistant Medical Officer to the Fulham Fever Hospital.
HAYCOCK, C. H., M.R.C.S., Medical Officer for the Bow District of the Crediton Union.
FERRUDOCKE, C., M.R.C.S., L.R.C.P. Ed., Medical Officer to the Vale District of the Winchcombe Union.
REYNOLDS, J. J., L.R.C.P. Lond., M.R.C.S., Assistant Surgeon to the Portland Convict Prison.
RYAN, J., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer for the Second District of the Northleach Union.
THISTLE, F. T., L.R.C.P. Lond., M.R.C.S., Senior House Surgeon to the Torbay Hospital.

Births.

BAKER.—Oct. 25, at 9 Idrome Terrace, Blackrock, the wife of A. W. W. Baker, M.B., M.Ch., of a son.
GROUND.—Oct. 24, at Maidstone, the wife of Edward Ground, B.A., M.B. Cantab., of a son.
SMITH.—Oct. 27, at 63 Richmond Road, Barnsbury, Gilbert T. Smith, M.R.C.S., of a son.

Marriages.

HANDYDE—MCNICOLL.—Oct. 26, at St. Helen's, Lancashire, Arthur Handyde, L.R.C.P., L.R.C.S. Ed., of Raristown, to Emily, daughter of R. McNicoll, M.R.C.S., of St. Helen's.
PLAYFAIR—MACDONALD.—Oct. 26, at Cloughton, Birkenhead, David T. Playfair, M.B., C.M., of Bromley, to Catherine, daughter of J. Macdonald, of Birkenhead Park.
STOKER—MACGILLYCUDDY.—Oct. 28, at St. Stephen's Church, Dublin, George Stoker, L.K.Q.C.P., M.R.C.S., of 8 Cadogan Terrace, London, E.W., to Agnes, eldest daughter of the late, and sister to the present MacGillycuddy, of The Rocks.
WOLRIGE—KEATING.—Oct. 26, at St. John's, Bathwick, Bath, Herbert E. R. Wolrige, M.R.C.S. and L.R.C.P., of East Knoyle, Wilts, to Annie Louise, daughter of Lieut.-Colonel A. Keating, Retired List Madras Army.

Deaths.

ANDERSON.—Oct. 22, at Hillington Heath, Uxbridge, William Alex. Anderson, M.D. Aber., F.R.C.S. Eng.
BROUGHTON.—Oct. 14, at Amesleide, Francis Broughton, F.R.C.S., late of Her Majesty's Indian Medical Service, aged 61.
HOLLIS.—Oct. 19, at his residence, Alvraston, near Derby, Wm. Hollis, Surgeon, aged 76.
HALPIN.—Oct. 23, at Arrah, Bengal, from a fall from his horse, Surgeon John N. Halpin, M.D., T.C.D., Bengal Medical Department.
PARNELL.—Oct. 23, at 17 Merchiston Avenue, Edinburgh, Richard Parnell, M.D., F.R.S.E., aged 72.

CASE OF VASO-MOTOR NERVE DISORDER.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.,
Physician to St. Mary's Hospital.

A. L., æt. 25, seen June 16th, 1882. Suffering seven years with headaches and "bilious attacks." At home she has headaches almost every day; the bilious attacks occur about once a week. In the latter she has palpitations of heart, and fainting, becomes quite unconscious for a few minutes, quite cold and stiff. She has also severe pain at the lower lateral parts of abdomen, lasting in paroxysms for several days. Always faints when that pain is on her. Vomiting also occurs in the bilious attacks. A paroxysm of pain sometimes lasts all day long. Nights are not good; she wakes up at times with palpitation and dyspnoea. Catamenia are very scanty, and the intervals are long, six weeks or more. Expression of countenance morose. Tongue quite clean. Appetite pretty good. Bowels very constive. Hands and feet apt to be very cold, but also get hot, too, are either very cold or very warm. Head often gets hot, and face flushed. Heart's sound full and clear; action regular. Pulse not at all cordy. Has pain often at lower back and left side, and much bearing down at times. Has been examined by a well-known gynecologist, who told her that the womb was too large, and the vagina contracted, as she stated. She also spoke of having copious leucorrhoea, but this did not appear to me to be the case. I found the vagina normal, the hymen intact, the uterus rather large, but well up, mobile, not displaced; there was nothing morbid in the arches, no undue heat of the parts, but over-sensitiveness. No ovarian tenderness now, but it was stated to be present at times. She used to be a great walker, but cannot walk much now, because she gets so tired. Her hands were cold and red. I took two radial tracings with much difficulty—v. (1). Both were miserable specimens, the rises extremely low, sloping, with rounded tops. No better tracings could be obtained with higher pressures; for these the pressure was 0. I then

sent her out to walk round the square briskly, and tried again when she came back, but the result was even worse. Her hands were absolutely cold and livid, and a pale pressure spot disappeared very slowly. I then made her inhale nitrite of amyl, which flushed her face very much indeed, and improved the pulse materially—v. II. Her face became quite hot and red, just as it does—she says—under any excitement. The flushing caused by amyl nitrite soon subsided. She resides in the country, in a bracing air. Takes tea twice a day (forbid). Is subject to ulcerated chilblains in winter. It was evident that the heart was not at fault, that the smallness of the radial pulse, and the capillary congestion of the parts depended not on want of driving power, but on excessive arterial constriction. I had seen the same, of course, in healthy persons during cold weather, and had taken a tracing—v. (III). This tracing was taken on a cold day, when the subject's hands were of a dull red; a pale pressure spot lingered long, and the pulse was so small and weak that it was very difficult to get a tracing. But in this there were no other symptoms, the stagnation was purely local, and confined to a small area. Here the case was different; the arterial constriction could not (in June) be the result of cold, grave symptoms were present, and it was at least a reasonable hypothesis that these depended on undue vaso-motor excitability, no rare occurrence in young persons in minor degrees. The hyper-excitability might be either primary or reflex, i.e., secondary to some visceral or other lesion, such as uterine displacement or ovaritis. Such conditions notoriously are possible causes of grave nerve disorders, and should always be carefully sought for in every refractory case. But I think the frequency of their occurrence has been over-rated, and the examination I made did not reveal to me the existence of any indubitable. Besides, in the patient I had to do with there were clearly grave reasons for eschewing local measures, if they were not absolutely necessary. A third possibility was that the hyperexcitability was of toxic origin, the toxic matter in this instance, as in sundry others, being the bi-daily dose of tea. This, however, I did not deem adequate to be the sole cause, and so, while forbidding it, I resorted to drugs to correct the morbid

state of the nerve centres. To think of hyperexcitability in a patient is for a physician to think of bromide, to which I added digitalis, desiring it, however, to be omitted every third day. The dose of bromide was gr. xv., of tr. digitalis Mx. The digitalis was suggested by the evident affinity of the case to epilepsy, where it has long had a repute, which recent observations of Dr. H. Jackson seem to justify. I also gave a teaspoonful of cod-oil in the day, and desired her to take Mijj. of a 1 per cent. solution of nitro-glycerine at one or two hour intervals during the so-called bilious attacks.

June 23rd.—Has slept well since I saw her. Had a bilious attack yesterday, but had no vomiting; could not vomit. Has had no headaches till yesterday. She feels better, but very weak. Hands much warmer. Tracing with pressure 28 grammes fairly ample, readily obtained.

28th.—Last two nights she has been troubled with nightmare and palpitation, and a feeling as if she was going to die. Has taken tea twice since 23rd; to leave it off entirely. Pt. mist. c. sodii bromidi gr. xxiii. ad ʒj.

July 6th.—Is very much better; feels quite well. Hands are much warmer, and of a better colour than they used to be. Catamenia have occurred with very little pain, and in much better quantity. No bilious attack. Tracings of good amplitude—v. (iv). Hands quite warm to-day, and face flushed after brisk walking. Often has pain in right side and back after such exertion.

Sept. 13th.—A report sent me by her father states that so far she has had no relapse, but, on the contrary, is gradually and steadily improving, and quite cheerful and spirited. Treatment continued regularly. A specimen of the urine which I had omitted to examine previously was clear, of medium colour, sp. gr. 1022, not albuminous, deposited no renal epithelium or casts, only flat scales.

The above record seems to me of interest, chiefly because the pathological condition was diagnosed—not a mere name affixed—and because successful treatment was rationally inferred from the diagnosis. This I hold we ought to aim at in every case, though we too seldom can attain it. So far as I could judge the predominant defect in my patient was what I have stated. But there were times in which the opposite condition of heat and hyperæmia from arterial relaxation prevailed. These occurrences may have been necessary results of previous undue excitation, and not primary errors. However this may be, there was clearly no indication for making them the object of treatment. On the other hand, the headaches, the scanty and rare catamenia, the debility, the attacks of rigidity and unconsciousness, the ovarialgia, the ulcerated chilblains might well be regarded as the results of insufficient blood supply in their several localities. It is, perhaps, too much to imagine that the state of the circulation within the cranium, or in the ovarian plexus, or in other internal sites, would ever be so gravely defective as it was commonly in the hands, where the cutaneous capillaries were engorged with semi-stagnant blood, where the blood when displaced by pressure slowly and languidly crept back into the vessels, and where the nutrition was so enfeebled that in winter time actual ulceration occurred. If such a condition existed in the grey convoluted surface of the hemispheres most serious impairment of their functional power would surely ensue; and when present in minor degrees, it cannot fail to be injurious. Could we see such a brain during life we should certainly pronounce it congested, and too many I fear would straightway conclude that it was over-supplied with blood, whereas the very reverse is the case. Let the arteries be relaxed, and blood flow freely into the small vessels, let the circulation become active and brisk, and the semi-stagnant fluid feel the

impulse of *vis a tergo*, then the congestion will speedily disappear and functional power be restored. Just as in embolism of a terminal artery the corresponding capillary district becomes loaded with stagnant blood, while the vascular walls decay, so is it in minor degrees of similar change depending on arterial constriction. Deficient blood-supply conditionates capillary engorgement and remora of the current, and on this there often comes damage to the delicate walls of the engorged vessels, and more or less leakage. It should never be forgotten that it is not the amount of blood contained in the vessels of a part that constitutes hyperæmia, but the amount of blood which passes through its vessels in a given time in excess of the normal.

The more copious catamenial flow after the arteries had been opened up is very noteworthy as confirming the above views, and suggests a similar therapy in certain cases of amenorrhœa. I do not forget, however, that Dr. Meadows has obtained very good results in cases of ovarian menorrhagia from the administration of bromides. This result is less easy to understand than that which occurred in my own. Supposing, however, the ovarian nerves to be unduly excitable, they may exert an inhibitory action on the uterine ganglia at the menstrual period, and so cause excessive blood flow in the uterus. Bromide by lessening ovarian excitability may lessen this effect. Inability for much muscular exercise was a marked feature in my patient, and that want of free blood-flow in the motor organs was (as supposed) its cause, is rendered very probable by the case of a friend, who in warm weather could walk 25 miles a day, but in cold weather was languid and feeble. The effect of exercise on the hands when I first saw A. L. was to aggravate if anything the state of coldness and lividity. This is analogous to a case related by Sir J. Paget, where a male found that whenever he walked far or fast his feet became cold, white, and numb, while when he rested they flushed red and hot. In both instances, especially in the latter, the vasa nerves of the lower limbs were excited at the same time as the muscular, and the blood-flow impeded. The rule in ordinary health is that the two sets of nerves alternate in their activity, but if the vasa are very excitable this alternating faculty is lost, and both get excited together. It will be observed that while my patient's hands were of a livid-red colour from congestion, Sir J. Paget's patient described his as being white and cold. I do not know on what the occurrence of congestion or non-congestion depends, but both states may exist in closely-adjacent areas at the same time. In "Peaks, Passes, and Glaciers," vol. iii., p. 421, it is stated that the guide's hands on one occasion "were really in a dreadful state, the backs of a livid purple, the palms quite white, and the whole curled round and stiffened." The headaches and bilious attacks were evidently of the nature of migraine, a disease which, at least in some instances—as in Du Bois Raymond's—seems to be largely dependent on arterial constriction. It is probable that it was so in A. L. But I do not think that vasa spasm was the sole cause of all the phenomena. The condition of hyperexcitability, which we must assume to have existed in the vaso-motor centre, could hardly have been confined to it, but in a modified form must have prevailed in the intra-cranial sensory and motor centres. These organs, thus pre-disposed to morbid action, and consequently being habitually more or less deranged, were at times precipitated into graver aberrations by deprivation of a due supply of blood. The treatment, therefore, of the entire malady resolves itself simply into that of hyperexcitability. This was adopted and proved sufficient.

FIG. 1. A. L.—Pr. 0 for both. (a) at rest; (b) just after exercise.

FIG. II.

A. L. —Pr. 0. After inhaling nitrite of amyl. June 16th, 1882.

FIG. III.

G., in good health, set. 17.—Pr. 5. Hands cold and livid.

FIG. IV.

A. L.—Pr. 50. July 6th, 1882. Hands warm; she feels quite well.

THE CONTAGIUM OF GONORRHOEA.

By C. R. DRYSDALE, M.D., M.R.C.P. Lond.,

Senior Physician to the Metropolitan Free Hospital; Physician to the Rescue Society of London.

DR. ELKUND, of Stockholm, has sent me a manuscript in French, on the microscopic organisms seen in gonorrhoea. In order to arrive at some conclusion about this curious point in contagion, Dr. Elkund has made many microscopic examinations of gonorrhoeal pus, and also of the most superficial layer of the mucous membrane of the navicular fossa, which latter he removed by means of a small knife, used for microscopic dissections, which he introduced into the canal of the urethra to the length of about two or three centimetres. He studied this latter preparation in its natural state, being convinced, from experience, that this was the best way to avoid false conclusions. Sometimes he added a little acetic acid, or solution of aniline, as, for example, fuchaine, and also carmine, &c.

In the first place, he always found the gonococcus described exactly by Neissen, the diameter of which varies from less than 0.1 to 0.5 mm., and larger. These are as brilliant as pearls. The whole of the round cells called pus, are perfectly full of these, and they are also found in innumerable quantities in the inter-cellular liquid. Sometimes they move rapidly, sometimes they are united like a figure of 8, which, according to Neissen, proves that their pullulation takes place by scission. When tinged with aniline violet it is seen that the gonococcus is a flat plain disc, not a spherical ball; but Dr. Elkund cannot agree with those who maintain that these microbions represent the only specific part of gonorrhoea, since he has found similar and probably identical ones in acute and chronic disease of the intestines and lungs, and in ulcerative stomatitis. Generally, he thinks it the common office of these organisms to produce acute inflammation with desquamation of the epithelial cells, and the formation of pus cells which are filled by them. Indeed, these organisms represent troupes of miners in pathology.

Long ago the same writer found that in cases of gonorrhoeal cystitis, the cells of pus from the bladder were, as a general rule, furnished with appendices, either filiform or gemmiform. The pus and the exudation of the inflamed mucous membrane of the urethra contain,

without exception, a beautiful network of mycelial filaments. The principal filaments of the organism in question, which Dr. Elkund calls *ediphyton dictyades* have a transverse diameter of precisely 1 mm., and are perfectly clear and hyaline. These filaments anastomose with each other at all angles. The mycelial tubes here and there have complete networks of swellings, the limiting lines of which are either regular or very sinuous. The parasite in question, like all similar, is gifted with the power of propagation by the simultaneous lengthening of an immense number of mycelial filaments or fragments of secondary ramifications of those which proceed along the superficial layers of the mucous membrane, and which enter into the glands of Littre, Cowper, &c. It is truly exceptional for this little organism to burrow, like the one seen in diphtheria, so as to produce a general infection, for the firm fibrous tunic surrounding the urethra forms a solid rampart to prevent the advance of the mushroom, and the organic resistance of the patient is generally greatest at the epoch when a man contracts gonorrhoea.

As a general rule, the ramifications of the mycelium run most along the surface of the mucous membrane of the urethra, the fundus of the bladder, the ejaculatory ducts, the seminal vessels, and deferent canals, &c. In cases of chronic catarrh of the lungs after gonorrhoea, Dr. Elkund says he has noticed the gonococcus of Neissen, and the microbion just described in the sputa. He says that it is well-known that in the urine of scarlatina patients there are found filaments of mycelium long and hyaline, and alleges that in cases of female patients such urine may set up gonorrhoea in the vagina; and he has constantly found the same mushroom in the gonorrhoeal discharges of women.

Dr. Elkund says that in all his microscopic examinations of the pus, and superficial layers of soft sores he has found the gonococcus of Neissen and the *ediphyton dictyades*. He, therefore, believes the virus of soft chancre and that of gonorrhoea are identical. It is only, he puts it, the difference of the affected localities which cause the difference in symptoms, a solution of continuity being necessary to produce a soft sore. Surely, this is not worth alleging without experiments, and, as a rule, experiment flatly contradicts the assertion of Dr. Elkund.

The author also says that the microbions of balanoposthite consist in vibrios of putrefaction. Such are often found in the Douglas *cul de sac* of women, and may give rise to grave peritonitis in some cases.

Dr. Elkund made some microscopic experiments on various therapeutic agents commonly used in gonorrhoea. Saturated solution of borax did not seem to influence the organisms. A solution of perchloride of mercury had but little effect on them (1 in 10); but the tincture of *Eucalyptus globulus* had a good deal of power in causing the movements of the gonococcus to cease.

He has succeeded in curing patients, after disappearance of the acute stage of gonorrhoea, by means of cold sitz baths and injections of solutions of phenic acid, or chloral hydrate; 1 to 600 of the first, and 1 in 150 of the second; giving at the same time copaiba and cubebs. He found that in convalescence from gonorrhoea the gonococcus first disappeared from the urine. The *ediphyton* are very difficult to be got rid of.

The conclusions of Dr. Elkund then are—1. *Diagnosis*. The elements of diagnosis in gonorrhoea are comprised in the discovery by microscopic examinations of the presence of the gonococcus of Neissen and of the *ediphyton dictyades* in the pus which is examined. As to prophylaxis, extreme cleanliness is enjoined to prevent fragments of the latter entering the passages.

Treatment.—Introduce as soon as possible into the urethral canal of the male as deep as from 3 to 6 centimetres a bougie covered with carbolised oil, and made of iodoform and 10 drops of essence of *Eucalyptus globulus* with cocoa butter 2.5 grammes, which is then allowed to liquefy in the canal. Excoriations he recommends to be

touched with a hair brush dipped in a solution of iodoform in essence of eucalyptus (1 in 10).

The cure will follow in proportion as the microscopic organisms can be killed by this treatment. The remedy recommended by Dr. Watson Cheyne, *i.e.*, of bougies as above mentioned is an excellent remedy, according to Dr. Elkund.

I have no means of saying how far Dr. Elkund is right in his assertions as to the presence of peculiar microscopic appearances in gonorrhœa, but there seems a possibility that it is so. I do not agree with him, however, when he talks of the identity of the virus of gonorrhœa with that of soft chancre, for I have not been able to produce the latter on patients by inoculating them with gonorrhœal pus. Syphilis eventually will, in all probability, be found also to have some special germs.

MINOR SURGERY CASES IN COUNTRY PRACTICE IN BYGONE TIMES. (a)

By G. KINLOCH H. PATERSON, M.D., M.R.C.P.,
L.R.C.S. Ed., &c.,
Perth, N.B.

(Concluded from page 350.)

CASE I.—J. S., æt. 25, labourer, well-formed, and living in the village of M—, had been complaining of pain in left side of his abdomen for several days previous, and finding himself getting no better of it, I was sent for to visit him. Soon after I was at his bedside; a healthy young man in appearance, and of a good-like constitution. On examining the seat of the pain, which he said was increasing rather than lessening—mostly subcutaneous—it seemed to me to extend over that adjoining, or was connected with the sigmoid flexure of the colon and cæcum. The external part of the wall of abdomen affected felt hard underneath it, swollen to some extent, and was also of a circumscribed formation. His pulse being full and bounding, took blood away by venesection to twelve ounces fully, which gave considerable relief to the pain. On the following day repeated it, with a similar good effect, and soon after applied a fly blister, as well as a continuation of poultices to the part. Still the pain recurred from time to time. The appetite also was beginning to be less, and his bowels inclined to constipation. For the latter I ordered emollient injections *per anum* now and then; but further on in my attendance his former ruddy countenance came to be gradually of a paler hue. The strength of his body or frame went on decreasing, and latterly his whole appearance and system, owing to the length of his illness, looked very unfavourable and ominous. The part or spot complained of had now become, as well as felt, much more soft, and consequently, being satisfied in my own mind by the feeling of fluctuation that, without doubt, I had an abscess to deal with; which ensuing, what, at this crisis, was there to be done? An opening was by myself proposed. This his parents and my patient declined. I pressed it peremptorily being had recourse to as the only hope I could give him for a chance of his life, and from his having so long, by this time, been under treatment by me—already three weeks. He gave his consent at last. Speedily fixed was the day; and with a narrow, straight bistoury I made an incision into the centre of the external integument of, and through to, the abscess. On withdrawing it there came out foetid, hissing, gaseous air and matter. Ordered a stimulating poultice immediately after; to be repeated and constantly kept applied. In about eight days used again the bistoury (the second time) in another part of the external covering of the abscess, which timeously and sufficiently gave vent to the remaining confined purulent, thickish matter. After this he began to rally onwards, and at the end of another fortnight eventually he rose out of his bed, in which—a few

days before and after the operation, although as well as possible—he had been kept by my orders on warm, cooling drinks, fresh-made, nourishing broths, and along with good cheer (*q. s.*). Owing to his death-like look, he seemed as if he had come back from his grave. His health and strength, however, ere very long, returned to him again, to the joy, not only of his aged and respected parents, but also to his loving sister, who chiefly and unweariedly, as well as anxiously, waited on her brother in their humble, Scottish-life home. In the above case, by assisting Nature to bring the *materies morbi* to the nearest and safest outlet, her beneficent work was shown and accomplished well, truly.

CASE II.—J. G., æt. 27, ploughman, married. Was requested to visit him about a week from the beginning of his present illness: I saw him soon after. His countenance looked so changed from his former appearance that, if I had not seen him occasionally before this, I would have failed to know who he was—by name or in person. The face all over was very much swollen; the eyelids also were swelled outwardly, and closed, from oedema. Any pain he felt was on the right side of his face, over and a little beneath the protuberance of the cheek bone. Ordered continued poulticing of the pained part. On the following evening he complained when a certain small spot of the latter was gently and carefully pressed with the fingers of pain in it. On re-applying the pressure more than once, there seemed perceptible fluctuation to some extent. Immediately, with the bistoury, I opened the part referred to as deep as I thought could be done with safety, when about two teaspoonsful of thick pus flowed out, assisted by pressing together the integuments around the incision; re-applied the poultices; advised a continuation of warm drinks; also his bowels to be moved daily by laxative salines, or senna and *s. magnesia*; mild food, of a farinaceous kind; no stimulants; the face and eyelids to be shaded as much as possible from the light, and inward quiet of mind. The facial or erysipelatous swelling afterwards gradually each day diminished, and in a week from my first visit he was up and going about. He seemed not to be certain what brought on, or was the cause of, or commencement of it. To my thinking, it arose from, as it might well be, the part incised having previously received the poisonous sting of some insect; also from the fact of the time of the year, it being about the end of his master's harvest, when he fell ill. His wife, during his sickness and facial disfiguration, was blythe and truly dutiful, which, in his case, had an excellent salutary effect.

CASE III.—H. N., ploughman, married, who had been laid up with sore throat for several days before my services were requested. Found him at the time of my visit sitting in a crouching position in a corner of the usual fireside of the house he dwelt in; he looked ghastly pale and weakly. On examination, upper and lower teeth and jaws were closely approximated, or in a state of lock-jaw; quite unable to get any kind of drink, far less food, for the past three days swallowed; the saliva had been and was still flowing now and then by the small opening between his teeth out of his mouth; his breath smelt very offensive; and fearing, therefore, and from also the outward feeling of enlargement on right side of his throat, that there was likely an unusually large tonsillar abscess, and seeing the critical and far from undangerous condition the poor man was in—"worse than foe," openly, seemingly to him—I lost no time, and at once resorted to the following improvised surgical plan:—I speedily got two common ale-bottle corks, divided one in two; with each half and the help of the handle of a kitchen *horn* spoon, pressed is carefully through between the teeth on each side, and, at soon as I had a wide enough opening, wedged in my pieces of cork well back towards the condyles. On these being well fixed, I then recollected that I had my tooth instruments with me, as the messenger did not tell me how bad my new patient at this time was; the claws of the former being removed already, I put into the aperture at end of the steel portion of the key a short firm iron pin,

(a) Read before the Perthshire Medical Association, June 2, 1882.

having a sharp point, about half an inch beyond latter, or farthest outwardly, and by narrow strips of cotton rag tightly bound it all round with these; screwed on the tooth handle; immediately when I found my temporary expedients each keeping their places for introducing it, with the hand thus fitted up as it was, holding as well as possible on a line to the right side of his mouth and throat, in and down to and through the abscess it went. Luckily for him, poor man, when withdrawing the instrument I had the presence of mind instantly to pull his head forward, which allowed the pent-up foetid matter to escape the more freely out of his mouth. As soon as he was able to speak, with a low voice he said, "You have saved my life, doctor; I feel relieved and better now." Ordered warm emollient applications outwardly, and cleansing gargles for his throat inwardly; also fresh soup, broths, either for drink or his diet, not forgetting grateful thankfulness; and also quietness; the former were very duly attended to by his cheerful and active wife. In the course of a week or a little more afterwards he was well, and again going about his ordinary employment.

CASE IV.—Mrs. R., set. 35, the wife of a labourer, came under my care for mammary abscess of her left breast. At first sight of it I was rather amazed from its size. She was strong and well-formed, ordinary tall, broad in chest. On examination, found the breast was greatly enlarged, round in shape, and hung down quite pendulous-like; it was hard all over, except at one part where it was, seemingly, to point from its feeling soft. In the latter I made, with the bistoury, a small, though deep enough, opening, after which a large quantity of unusually offensive purulent matter came away, but by careful attention afterwards it healed all right. Not a few of very healthy industrious working women, married and mothers, living in the country, and also in the city, will suffer pain, often intensely, and delay, rather than seek or apply for medical advice for ailments of their breasts, instead of which they ought, for their own sakes and their little ones, to seek it early. In allusion to the phrase "pain is a friend," doubtless so it is, when any part of the living human frame has been, or is attacked with, or racked by it; and far from being unreasonable to hope that the benefit to be derived from its first or after occurrence, is to obey and attend to its warning call, either for alleviation of the agony or cure of it. Lastly, while endeavouring to give ready relief, and in showing always mercy, may we remember also to try to save our patients from as much pain as possible.

The narrow incisions, sufficiently deep, with the bistoury, which I preferred instead of larger openings, and made by me in above cases of circumscribed abscess, along with the external applications used, were, I may be allowed to say, the best of the two, to my humble thinking, and tended beneficially also to exclude not a little of the surrounding air from the openings by incision in those bygone times.

"THE GERM ORIGIN OF DISEASE." (a)

By F. J. B. QUINLAN, M.D., F.K.Q.C.P.,
Physician to St. Vincent's Hospital.

AFTER explaining the details of the action of the yeast plant in fermenting a saccharine solution and converting the sugar into alcohol and carbonic acid, Dr. Quinlan said: "Similarly in the human body, when the germs of measles enter through the respiratory passages, a period of what is called incubation occurs; the original germs are multiplying. At last the spores are thrown out, and an immense effervescence and fever, with peculiar eruption on the skin and respiratory passages ensue, and go on until the fermentative material in the system is exhausted; and the patient is left convalescent, and as a rule protected against the recurrence of this particular disease. In 1868, M. Chauveau showed that the infective matter of cowpock, small-pox, and

other zymotics consisted of a fluid containing vast numbers of minute particles, and that by diluting and diffusing in water until the particles subsided, the infection power of the fluid was gone; but that as long as particles remained they would multiply indefinitely in the human body. In their memoir on contagion, published in the *British Medical Journal* of the 21st of last January, Dr. Braidwood and Mr. Vacher describe the infective matter of measles as consisting of numbers of sparkling colourless bodies in the breath of patients, like those found in vaccine lymph, but larger. In small-pox minute organisms are found in the fluid of the pustules, and in typhoid fever Dr. Klein has found them surrounding the affected intestinal glands. The starting point of all these investigations was the discovery that the blood of animals, dead from splenic fever, swarms with minute organisms resembling little rods, and therefore termed bacilli, which multiply and throw out spores just like the yeast plant. The bacilli of splenic fever can be cultivated artificially in an organic fluid, and the crop can be continued from fluid to fluid. If after seven or eight such successive crops a rabbit or a guinea-pig be inoculated with the last fluid, it rapidly dies of the original splenic fever. Still more curious, it was microscopically proved that the blood of animals, where the rods only were developed, rapidly lost its infective power; but that once the spores were thrown out, it retained it for years. This at once explained the reason why, while some stables and sheepfolds were, after an outbreak, fitted for the reception of animals by mere disinfection, others could not be so cleansed, and had to be destroyed."

The lecturer now entered into a description of small-pox, of vaccination, and of re-vaccination, explaining his belief that vaccinia was a natural attenuation of variolous poison occurring by the passage of the disease through the system of the cow; and that it exactly resembled the artificial, and preventive, attenuation by Pasteur of the zymotic poison of splenic fever, and proceeded to say: "In considering this matter we must remember that the hard and fast lines between different diseases, as laid down in text-books, do not exist in Nature, and that types of disease, like domestic animals and plants, are constantly undergoing evolution and modification of type owing to surrounding circumstances and treatment. The most remarkable recent instance of this is the curious experiment of the Fraulein von Chauvin, who by a course of physical treatment converted a number of Mexican water-breathing axolotls with gills and rudimentary lungs into ambylostomas, similar animals living on land and with lungs. Another disease the result of germs is typhoid fever, in which multitudes of infective germs are thrown off in the ejecta of the patient. Should sewage containing these get into the water supply of a district a whole community may be infected, as occurred at Bangor, North Wales, this year; and a similar result on a smaller scale has frequently happened when water so polluted has been made to do the duty of 'the cow with the iron tail.' Typhoid fever is popularly supposed to be due to bad smells and sewer gas, but it is really due to the germs contained in these; and in reference to this there are two noteworthy points. One is, as shown by Carpenter, that if sewage be poured through Italian ryegrass the spongioles destroy all germs, and leave the resulting fluid so far harmless. The other is, that although germs will pass through the finest filters, filtration through spongy iron entirely destroys them. The well water of Antwerp—now rapidly becoming the greatest emporium of Europe—is brackish, and unfit to drink; accordingly the inhabitants have recently got up fine waterworks in which they apply this spongy iron filtration—which is the invention of Professor Gustav Bischof—on a large scale to the water obtained from the river Nette. Dr. Frankland has visited the Antwerp waterworks at Waelheim, about fifteen miles above that city, and reported on the results of his inquiry. He attaches especial value to the fact that spongy iron filtration 'is absolutely fatal to bacteria and their germs,' and he considers it would be 'an invaluable boon to the metropolis if all water supplied from the Thames and Lea were submitted to this treatment in default of a new supply from unimpeachable sources.' Another remarkable germ product is the malarial fever of the Roman Campagna, of Algeria, and of other places. Noticing that it always ensued on the breaking up of new ground, Klebs and Crudei examined this soil and found germs, which, entering through the respiratory passages, produced the well-known malarial

(a) Abstract of an Inaugural Address delivered at St. Vincent's Hospital.

affection. It is well-known that the daily use of a small quantity of quinine by the dwellers in ague districts will prevent this affection; and further, that when it breaks out larger quantities of this drug will cure it. Quinine is a powerful protoplasmic poison and destroyer of germs, and its curative action in ague becomes at once intelligible. There is excellent reason to believe that rheumatic fever is also a germ disease; but as this is argued from analogies, and not yet practically proved, we must speak with reserve on this point. Sunlight is a powerful destroyer of germs, which are, on the other hand, much favoured by dirt and damp, and that is the reason why no house is wholesome in all its parts unless it face either east or west, so that the sunlight during half the day may penetrate every part of it; likewise why cellars and deep basement storeys are unfit for human habitation. Nothing has as yet been done to attenuate the poisons of measles or scarlatina; but if we can argue from what has been done in similar cases, it is probable that it will ere long be done; and these maladies, which now rank almost as inevitable diseases, will become as little so as small-pox. We are accustomed to them, but the amount of collective injury which they do to the community is immense. When they break out for the first time in isolated communities, and attack young and old simultaneously, they amount to actual plague. This occurred a few years ago in the Fiji Islands immediately after their annexation and civilisation. Later back it happened in the Faroe Islands, where the whole population were at once laid low, except some very old persons protected by an outbreak which had occurred about sixty years previously. One of the islands escaped in a very curious way—it is the southern member of the group, and is twelve miles from its nearest neighbour. Learning what was going on in their sister islands, the Sudeese men drew up their boats into their island, and, maintaining an armed guard day and night for three months, threatened instant death to any stranger who would dare to land. This rough quarantine proved perfectly effectual, and when the neighbouring epidemic had burned itself out, this sanitary Thermopylæ stood unharmed. This brief review of germ disease would be incomplete without some notice of its latest and most brilliant advance in the discovery of the tubercle bacillus. Up to a recent period it was generally believed in these countries that pulmonary consumption, although of a hereditary type, was not an infective disease. In Southern Europe the contrary opinion has always prevailed; and even here cases occurring of undoubted communication of the malady between individuals brought in close personal contact, caused many a doubt to the thoughtful physician. The matter was set at rest by the discovery of Villemin that tubercle was inoculable, and this was followed up by Koch, of Berlin, who discovered the tubercle bacillus, cultivated it, and communicated it to animals. This bacillus is a species of alga, and is found swarming in phthisical cavities and in the expectoration of consumptive patients. Externally, it is very similar to other parasites, which have nothing to say to tubercle. Herr Koch pointed out that the tubercle bacillus can be easily distinguished from all others by its behaviour in the presence of certain aniline dyes. As this bacillus is about the third of the size of a blood globule, any reasonably good microscope will detect it; and we have the diagnosis of pulmonary consumption thus reduced to the simplicity and exactness of a chemical test. The matter was now taken up by the German Government, who established the Imperial Health Office, the creation of Prince Bismarck, appointed Koch as its director, and made him a Councillor of State; for in Germany medical science is honoured and decorated, instead of being hunted into foreign countries by antivivisection acts. Supplied with ample means, Koch pursues his investigations in a spacious building, and provided with all necessary assistants and accessories. The animals experimented upon are all kept in cages, and each cage represents an experiment, and the greatest care is taken to secure proper ventilation and to avoid all cases of disease arising from defective hygiene. There are curious differences in the susceptibility of different animals to tubercular infection. Rabbits and guinea-pigs are most susceptible, and barn-door fowls still more so. It was at first believed that dogs could not be infected; but it has been found that they can, especially if wholly fed on vegetables. As a rule, herbivorous animals are much more susceptible than carnivorous, a fact which explains the well-known potency of a meat and nitrogenous diet in saving consumptive patients. Further, an abundance of pure air constantly changed is a great protective,

and air for a long time re-breathed an injury—another striking analogy. Consumptive infection is carried by the breath or expectoration of consumptive patients; and there is no doubt that while many persons are very susceptible to infection, particularly when in a lowered state of health or badly nourished, or when the tendency is hereditary, many others are not susceptible at all. It is also a consoling fact that tubercular bacilli, unless kept outside the body at a temperature of 100 degrees, at once die, differing, fortunately, in this respect from those of splenic fever, which, as already described, sometimes linger for years where animals are kept. Time forbids me to dwell longer on this interesting topic."

THE MODERN IRISH SCHOOL OF MEDICINE AND SURGERY.

THE introductory address was delivered in the Richmond Surgical Hospital, Dublin, on Thursday, Oct. 2nd, by Mr. Wm. Thomson, one of the surgeons. He took for his subject the influence which medicine has had upon operative surgery, and having shown the high rates of mortality after operation in spite of all improvements up to the introduction of antisepticism, he drew a comparison between the new and the old systems. We hope to give an abstract of his remarks in our next. His concluding observations—which are eminently appropriate to the letter of Dr. Thompson, of Omagh, published by us last week—were as follows:—

The rapidity with which medicine and surgery and the subsidiary sciences are advancing is one of the marked characteristics of the latter part of this century. At no time were there workers so many, so thorough, so industrious; and at no time have the demands upon surgery been so urgent. The School of Medicine and Surgery in Dublin to-day is in no sense inferior to any that has gone before. Its physicians are as able, its surgeons as bold and dexterous, its teachers as profound, at least, as they have been at any time in our history. Very lately a comparison has been drawn between the men of to-day and those of thirty years ago, and I need not say that, coming from the north of Ireland, the judgment has not been flattering to Dublin. It never is in anything. And here, in the presence of men whose names are known throughout Europe and the world as physicians and surgeons, as men of advanced scientific attainments, as educated gentlemen, I repudiate with all the energy I can command the statement that the teaching in this city is degenerating. The author of that remark had no better opportunity than I had of judging of the great men who are gone, seeing that we are of the same professional age. In this place we have never forgotten to speak with admiration and respect of the teachers who have passed away. We have always declared their merits—great for their opportunities—but we have avoided falling into the fallacy of regarding a man as great because that man was old or dead. The faculty of finding out the greatness of a man after he is gone is proverbial; but it is not so easy apparently to measure the attainments of our contemporaries. I do not dissent from any eulogium upon the dead past, but I do dissent from the miserable doctrine that with it has been buried all genius and power, and that for us only remains an inheritance of commonplace capacity. Thirty years have made a tremendous difference in the number of highly-informed members of the profession. Teaching, as we know it, was then in its infancy; the men who were profoundly instructed were few, and those who had commanding powers shone by contrast above the mediocre level. But that state of things no longer exists. Competition in life has become keener; superior teaching has become more general; a larger number of pupils with better trained minds are entering the profession, and the average of intellectual height has been considerably raised. It is no wonder, then, that, with a great general advance, it should be difficult for any casual thinker to believe that there are as many heads above the crowd as there were in former days. I repeat that there are more; that clinical teaching has not degenerated, but improved; and that everywhere throughout this city there are men who hold no second place in the list of teachers—who have done honour to the great Irish School of Medicine and Surgery.

To protect its honour, to emulate its fame, to uphold wherever you go the high character of your School—these form part of the trust which is committed to you. But,

rising above all petty jealousies and mean rivalries, let your object be to acquire by diligence the knowledge which will help you to do the greatest good to the greatest number of your fellows. It is sobering to think how often the chances for life or death will be placed in your hands, and the hopes and prospects of individuals or families rest upon your wise judgment or your shortcomings. So far as we can we will help you, so that you shall acquit yourselves as true men; and rest assured that you will give us no greater pleasure than to show yourselves in the future worthy pupils and loyal to the old Richmond Hospital.

Clinical Records.

GLASGOW ROYAL INFIRMARY.

Case of Fasciculated Sarcoma in Scarpa's Triangle of the Right Side.

Under the care of Dr. DUNLOP.

Reported by A. J. ENGELS, House-Surgeon.

MRS. S., *et. 36*, domestic, was admitted into Dr. Dunlop's wards on the 1st of July, 1882. The tumour when first noticed, seven years ago, was the size of a walnut; it grew slowly to the size of a hen's egg, but two months ago patient had severe pains in the back, and the tumour increased rapidly in size, and on admission measured $6\frac{1}{2}$ in. in length and 4 in. transversely.

On examination, the tumour was found to be firm, non-elastic, and appeared to be imbedded in the soft tissues; no attachment to bone, deep fascia, or skin. No impulse was communicated on coughing, the femoral vessels could not be made out, and there was no pulsation in the tumour, or in any of the arteries of the limbs. No loss of sensation motion of the limb, and no enlargement of the glands in the right groin. Family history quite satisfactory.

July 16th, 1882.—Patient was put under the influence of ether, and Dr. Dunlop removed the tumour from the muscular tissues in which it was imbedded. The only points of special interest in the operation were the number of enlarged veins which formed a complete network over and around the tumour, and gave rise to troublesome bleeding, and the obliteration of the femoral artery and vein throughout their entire extent in Scarpa's space. The circulation through the limb had been carried on principally through the profunda, which was seen to be enormously enlarged. The skin was brought together with silver wire and hair suture, and a large drainage-tube was introduced from below. The operation being performed with antiseptic precautions.

On the seventh day after the operation the patient was dressed with the usual precautions, when it was found to have partially healed by first intention; there was little discharge, and the drainage-tube was removed, also a few of the stitches.

27th.—Patient was again dressed under the spray, when the remaining stitches were removed.

30th.—When patient was again dressed the spray being stopped, and boracic lint dressing substituted for the antiseptic dressings. This was continued every second day until the 8th August, when the incision was entirely healed. The temperature was satisfactory throughout the treatment of the case. Patient was dismissed quite well on the 12th August, 1882.

Pathological History, by Dr. Newman.—The tumour measures nearly five inches in length, and varies in breadth from two and three-quarters to three and a-half inches; the external surfaces is irregularly nodulated and its peripheral limits are clearly defined, but there is nothing seen corresponding to a well-formed capsule. The cut surface is of a uniform pale reddish colour. On microscopic examination the tumour is seen to be made up entirely of moderate-sized fusiform cells, which lie mostly parallel to, and in close contact with, one another, except where they are separated by vascular canals. These canals are very numerous, and for the most part, of considerable size, and at some points they have become dilated and varicose, but, in no part of the growth is there any evidence either of old or recent hæmorrhage. At certain points the spindle cells interdigitate, so as to form distinct fasciculi which occasionally cross one another, and give the section when examined with a low power a somewhat lobulated appearance.

France

[FROM OUR SPECIAL CORRESPONDENT.]

TYPHOID FEVER.—The epidemic of typhoid fever in Paris shows but slight inclination to abate rapidly; however, a little improvement was noticed last week, and the hospitals which had to provide special accommodation for the emergency experienced a slight diminution in the number of patients admitted. It is worthy to be noted that the children have been mostly attacked, but persons of an advanced age have not escaped, several over forty years of age having been received in the hospitals. What is still more remarkable is the extreme rarity of the abdominal form and the very few lenticular spots observed. Diarrhoea was rare, and constipation the rule. As the most frequent complications, bronchitis, pulmonary congestion, pneumonia, and meningitis, especially among children, have been observed. As to treatment, the mode generally adopted was warm baths, purgatives, and enema of a solution of phenic acid. Sulphate of quinine in large doses, of forty-five to sixty grains, and even more daily, has been in great favour. Salicylic acid is under its trial also, and, in fact, every agent hitherto brought forward as specific in this disease is being put to the test, and the reports by-and-by on the epidemic and the success following the different medicinal agents employed will go a long way in elucidating the question as to what is the best treatment of typhoid fever. Dr. Moricourt considers the sulphate of copper to be superior to quinine or salicylic acid; he gives six grains of it in the twenty-four hours, and the same dose by the rectum, the enema to be repeated twice or three times in the day, according to the gravity of the affection. In the case of children the dose is one-half. The vehicle for the enema was decoction of Iceland moss.

ULCERATION OF ARTERIES.—At the meeting of the Société de Chirurgie M. Anger read a report on ulcerations of arteries in contact with pus in cases of osteo-myelitis. Two observations were cited, one being the case of a young man who was attacked with acute rheumatism of the knee; in the course of the affection there appeared a painful swelling in the popliteal space. An abscess was diagnosed, and when opened, blood alone flowed, and in abundance, but the patient got well, and the author of the report, M. Humbert, was of opinion that the artery was perforated, not by the knife of the operator, but by the processes of the inflammation. M. Anger cited another case which was very similar, and which occurred in his own practice. A young man entered the hospital with a tumour situated a little above the internal condyle of the right thigh. It was painful to pressure, and fluctuation was present, but no pulsation or *soif* could be observed. The patient was greatly troubled, especially at night, with lancinating pains traversing the tumour. Abscess beneath the periosteum was the diagnosis, and accordingly exit to pus was decided upon being given, and for this purpose a bistoury was plunged deeply into the swelling, and immediately a large quantity of blood of venous appearance and without clots came forth in a strong jet; there was no pus. On placing the finger in the wound a large cavity was found under the periosteum. The blood was arrested, and the wound, treated on antiseptic principles, healed gradually. M. Monod related two other cases, one of which was a cold tubercular abscess in the arm. The hæmorrhage was considerable from a branch of the axillary

artery; a ligature was placed, but the patient succumbed, and the autopsy discovered the existence of several perforations. M. Verneuil considered that unless there was septicæmia the arteries were generally proof against perforation. At the same time, he was not prepared to say that tuberculous alterations of the walls of the vessels could not affect the integrity of the coats, but he considered that further research was required to demonstrate it more fully.

ACETATE OF POTASH has been found, combined with salicylic acid, to be an excellent prescription for acute rheumatism. Acetate of potash, ʒvj.; salicylic acid, ʒss; syrup of orange, ʒij.; peppermint water, ʒvj. A tablespoonful every two or three hours, according to the severity of the symptoms.

TREATMENT OF SCARLATINA.—A practitioner recommends in the treatment of scarlatina an infusion of digitalis (leaves), and to continue its employment until the third week of the malady. In continuing this with unctions of oil over the whole body twice daily until all desquamation ceased, he avers that he never lost a patient out of 150 cases. Also, in order to prevent the development of diphtheritic inflammation of the throat, he orders the following mixture:—Chlorate of potash, ʒj.; tincture of iron, ʒij.; glycerine, ʒj.; water, ʒviij. A teaspoonful every half-hour.

Special.

THE FATAL INFLUENCE OF ANÆSTHETICS IN DISEASES OF THE KIDNEYS.

DR. LAURENCE TURNBULL, of Philadelphia, recently read an important paper before the Surgical Section of the American Medical Association on this subject. In it he dwells upon the absolute necessity of primary attention to the condition of the kidneys by an examination of the urine when an anæsthetic is to be administered in a serious operation, or when a fatal result may be anticipated. The subject has not been dwelt upon with sufficient earnestness by surgical writers, or in works on anæsthetics; the first publication on this subject was by Dr. Emmett, of New York; and the author's attention has been drawn to the subject recently by finding that many deaths unaccounted for in any other way were due to this cause.

In 1879, and again, before the American Medical Association, in 1880, it was stated by him that it is now a well-recognised condition that in disease of the kidneys anæsthetics almost invariably produce coma and death.

In his present paper he enumerates a considerable number of deaths from this cause, some of them only of very recent occurrence; also cases from chronic albuminuria, from twenty-four hours to eighteen days after the use of ordinary ether, as well as when hydrobromic ether was employed, but very few cases from chloroform.

Dr. William F. Norris also publishes a pamphlet in which two cases of death supervening unexpectedly, after operations for cataract, which occurred in his practice, are reported.

They presented four features in common: 1st. They were both anæsthetised with sulphuric ether; 2nd. They entirely recovered consciousness; 3rd. They died comatose, one in a few hours, the other eighteen days after the operation; 4th. In both cases a careful autopsy revealed no organic lesion, except Bright's disease of the kidneys.

The above cases before narrated, with those of Dr. Emmett's six cases of death, occurred from uræmic poisoning, while Drs. William Hunt and Montgomery each had one case, verified

by post-mortem examination. These go far to prove its fatal character, and need not have occurred if a proper and careful examination had been made of the urine before the anæsthetic had been given.

Mr. Agnew states, in his *Surgery*, on the supposed contra-indication, "Ether may be given with impunity to persons suffering with renal disease;" but in his cases has he had any post-mortem to prove that death was not the result of kidney disease? As well remarked by Dr. Norris, "because fatal results do not follow in all cases, we have no right to shut our eyes to those where the employment of anæsthetics apparently leads to fatal disturbance of the renal functions."

The kidneys are the active agents in eliminating the ether from the blood, and if they are unable to perform this office, and the skin is cold, moist, and inactive, death will supervene by accumulation of mucus in the lungs, or congestion of the brain, in true Bright's disease of the kidneys.

HEALTH AND FIGHTING EFFICIENCY.

"HEALTH and fighting efficiency," says Sir Frederick Roberts, in his closely-reasoned article on "The Present State of the Army" in the November number of the *Nineteenth Century*, "hang together more intimately than many imagine. Let sickness once fairly set its mark on a force, and battalions which, up to that time, did their work in a hearty cheerful manner, and were fit to go anywhere and do anything, are hardly to be recognised. Instead of the keenness and 'go' which gave life to everything, a stupor seems to have fallen over the men. Those who are not ill are oppressed by the fear that their turn is coming, and that they will be the next victims to the fever, cholera, or whatever the prevailing epidemic may be. No one who has seen troops in time of great sickness can doubt that disease and ill health are just as likely to be the cause of military failure as even indifferent strategy or want of discipline." Very momentous testimony is this, borne by one of the most successful and accomplished generals of the day, to the dependence of fighting efficiency on sound health, and therefore to the value of that department of the service which is especially charged with the guardianship of the soldier's health. If the issue of battles and campaigns depends as much on medical foresight as on military strategy, it is clear that those who exercise that medical foresight effectively should be not less highly esteemed and liberally rewarded than those who display ability in manœuvring or in leading troops. The public recognition of this truth—and its public recognition cannot be far off now that Sir Frederick Roberts has so boldly proclaimed it—must lead to the concession to the Army Medical Department of greater influence and authority than it has hitherto possessed. The country will come to understand that the least important part of an army surgeon's duty is the amputation of limbs and the treatment of gunshot wounds, and that it cannot consider itself in a proper state of defence until it has drawn into its military service the highest medical ability of the day, and has in its Army Medical Department a body of men skilled in sanitary science, abreast of the most recent advances in physiology and pathology, and armed with powers which will enable them to take effective measures for the preservation of the health of our troops in whatever part of the world they may be employed.

A curious illustration of the incompetency of a layman, even when learned and astute, to deal with problems in which medical considerations are involved, and of the importance, therefore, of medical participation to a far

larger extent than hitherto in all military councils and deliberations is afforded in Sir Frederick Roberts' article, from which we have quoted. That sagacious and experienced officer, in dealing with a simple question of vital statistics, falls into an error that the youngest surgeon in the service could not have committed, and thus conspicuously proves that even great commanders are at times in need of medical assistance. Desiring to prove that it is young men who especially suffer and die in India, he extracts from the Report of the Army Sanitary Commission figures showing that 6·17 deaths due to enteric fever take place annually per 1,000 strength in soldiers under 24 years of age; whereas only 2·73 deaths due to that cause to 1,000 strength take place in soldiers between 24 and 29 years of age, only 1·78 in soldiers between 30 and 34, and only ·71 in soldiers over 35. But he omits to mention, and is apparently ignorant of, the fact that enteric fever is most fatal in youth and adolescence in the civil population of all classes. The tables of the London Fever Hospital show that 73·13 per cent. of all cases of enteric fever are of persons under 24 years of age, only 10·15 per cent. of persons between 25 and 29, and only 5·34 per cent. of persons between 30 and 34. In estimating, therefore, the mortality from enteric fever in soldiers of various ages, in any way attributable to the circumstances of their vocation, it is necessary in the first place to determine the mortality due to that malady in males of like ages in the general community, and then to subtract this from the military mortality at the contrasted ages. The figures that remain when this has been done will enable us to judge to what extent the conditions of the service tend to increase the predisposition to enteric fever, or increase its fatality in young and old soldiers respectively. But the process indicated when carefully carried out, would greatly diminish the force of Sir Frederick Roberts' argument founded on the comparatively high rate of mortality from enteric fever amongst young soldiers in India. We do not question the justice of his conclusion. We are as strongly convinced as he can be of the unwisdom and inhumanity of sending boys abroad on military duty when their constitutions are not matured, but we desire to point out that a fallacy lurks in one of the grounds on which he bases his conclusion, and that his statement, as it now stands, is calculated to lead to an erroneous estimate of the part played by early military service abroad in increasing the mortality from enteric fever. Of course the fact that this fever is mainly a disease of young persons—a fact which has been confirmed by every observer—is an additional reason for not placing young soldiers, at those ages when they are peculiarly liable to it, in circumstances in which its other etiological conditions are most active; but the results of doing this as it has hitherto been done—rashly and recklessly—have not been so disastrous as might have been anticipated.

While pointing out where Sir Frederick Roberts would have been the better of medical guidance in the preparation of his article, we can bestow upon that article generally, in so far as it deals with questions upon which medical opinion may be properly expressed, unqualified praise. It is conceived in a scientific spirit, and worked out with courage, insight, and sound practical sense. It adds to the obligations which his country already owes this distinguished officer by pointing out blemishes in our present system which cannot be too speedily rectified. The sooner that medical men are allowed more voice than heretofore in army administration, and that steps are taken to prevent the despatch to India of drafts of

raw, undeveloped youths more likely to fill hospitals and graveyards than to grow into tough and vigorous soldiers, the better will it be for the popularity of the service, the security of the country, and the pocket of the taxpayer.

PROPOSED INSTRUCTIONS TO GERMAN MIDWIVES FOR THE AVOIDANCE OF PUERPERAL FEVER.

A COMMISSION has lately been sitting at Magdeburg for the purpose of considering the best method of preventing the origination and spread of puerperal fever. The deliberations have resulted in a series of proposed instructions to midwives, having for their aim the so-called antiseptic conduct of labour cases. This will be shown by the following propositions laid down by the Commission:—

1. Medical science has, for a series of years past, arrived at the fixed conviction that the great majority of cases of childbed fever depend for their origin upon the inoculation of recent wounds (produced more or less in every case of labour) by putrid (so-called septic) poisons.

2. These poisons readily cling—but in an imperceptible manner—to every kind of utensil that may come into contact with the woman in labour unless they are kept scrupulously clean.

3. But it is the hands and instruments of the obstetrician that have become known to be especially dangerous bearers and disseminators of the poisons, as it is impossible to avoid bringing these into contact with dangerous putrefying material.

4. Simple, and even repeated, washings with soap and water, as observation has shown, will not remove the poisons that may be clinging to the hands and instruments. The slightest trace of such a poison will, however, suffice to set up the gravest—yea, even fatal—childbed fever.

5. Wherefore it is the most sacred duty of every midwife, as of every physician, in other ways so thoroughly to cleanse the hands and instruments, and whatever other appliances may be brought into contact with the patient, that she may not be inoculated by any poisonous matter.

6. We are able, as we learn by observation, to destroy the poison, or, at least, render it powerless, by boiling water, and especially by the stronger solutions of carbolic acid (two to five per cent.).

7. The simple rinsing of the hands in carbolised solutions that are too weak can afford no protection against childbed fever. We therefore give, in the following, instructions as to the rational employment of the antiseptic material before, during, and after labour.

Then follow, in fourteen paragraphs, the details of the "Instructions for the Antiseptic Conduct of Labour and Childbed." As will be supposed, these instructions are founded entirely on the propositions laid down in paragraphs 1 to 7.

Paragraphs 22 to 24 deal with instructions to the midwife in case the lying-in woman is ill, No. 22 directing the midwife to call in medical assistance at once if the temperature rises or the lochia become offensive.

Twenty-three would fix upon her the duty of reporting the case to the district medical officer within twenty-four hours of her becoming aware of the nature of it.

Twenty-four directs the necessary washings and disinfections to be carried out by the midwife before venturing to attend another labour or lying-in case, and cautions her to cease her attendance on cases likely to prove infectious as soon as a suitable attendant can be found to supply her place.

Numerous references are made throughout the Instructions to the "Prussian Handbook of Midwifery for Midwives," of which, by-the-by, an English translation has been published in this country by Mr. Burton. (a) All this goes to show that the endeavour to educate midwives in Germany is a serious and painstaking one. Difficulties have been, and are being, met with, mostly having their origin in the low degree of mental culture possessed by the classes who follow the occupation of midwives. A recent suggestion by a district medical officer is to the effect that every midwife shall be compelled to take out at least eight days' practice in a lying-in hospital once in five years.

What a contrast all this offers to the condition of affairs in our own enlightened and free country! where any woman, idiotic or otherwise, who chooses to do so, may call herself a midwife, and charge herself with the life of any poor woman who may be ignorant or foolish enough to employ her. Paternal, or, as their abusers maliciously term them, "grandmotherly," Governments may impose restraints upon freedom of action that may be felt in many cases to be irksome, but it can scarcely be questioned that the balance of safety to human life lies on the side of that Government that does exercise restraint in all those callings in which life is affected.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 8, 1882.

OPENING OF THE SCOTCH SCHOOLS.

OPENING ceremonies, introductory to the current winter session at various schools of medicine in Scotland, took place on Tuesday and Wednesday of last week, the customary addresses forming a principal

(a) "Prussian Handbook of Midwifery for Midwives." Translated by J. K. Burton. London: J. and A. Churchill.

feature of the occasion. At Edinburgh, Mr. Chiene, newly-appointed professor of surgery in succession to the late Mr. Spence, delivered an inaugural lecture before a very crowded audience, consisting chiefly of students, the preliminary conduct of the latter being of the usually boisterous description. Subsequently, however, even the more obstreperously-disposed of the audience settled into an attitude of quiet attention; and Professor Chiene had the satisfaction of feeling that the really admirable address he had prepared was listened to by a sympathetic and appreciative assembly.

After paying well-deserved and manly testimony to his predecessors in the chair of surgery at Edinburgh, the orator proceeded to compare the present surgical treatment of wounds with that which ruled the practice of twenty years ago; and while insisting on the fact—to which Mr. Chiene is justified in expecting a cheerful and general assent—that the Edinburgh School has always been among the first to institute or adopt improvements, he claimed that present-day practice had been more than foreshadowed in the past history of surgery. The assumed ignorance of our forefathers is a demerit unjustly attributed to them in Mr. Chiene's opinion; and it is very probable that a large following will agree with his defence of the shrewdness and intelligence exhibited by the older surgeons. Although we must necessarily admit that empiricism then stood for scientific principles, it is nevertheless true that out of the old-time suggestions and deductions have arisen most of those brilliant applications of theory in practice to which the superiority of modern results is mainly due.

From this topic to the practical benefits ensuing to humanity from experimental research, and the many advantages to medicine and surgery accruing through the discoveries made by original investigators, was a natural transition; and in dealing with this part of his subject, Professor Chiene was no less happy than when discussing the more personal relations of his post. Claiming freedom for scientific workers, and immunity from vexatious obstruction, he urged the necessity of educating the public to perceive the importance to themselves of removing restrictions which hamper the development of higher qualities in the students who resort for instruction to such centres as the great schools of medicine; and, in concluding a highly-interesting and valuable address, he vigorously denounced the view that teachers were to be regarded as "polishing machines" merely, rather than as prosecutors of such labours as should result in increased knowledge and greater usefulness.

Professor Greenfield's opening address to the class of pathology was chiefly devoted to description of the improvements introduced during his term of office in the arrangements made for practical instruction in the subject of his demonstrations. The necessity of these increased facilities was shown to have arisen out of the growth of the subject, and its requirements for study and teaching; and considerable as the advance in this subject has been within the last few years it was prophesied that fifteen or twenty years hence even the vastly augmented resources now at disposal in the university

would be found wholly inadequate to its needs. The scope and reasoning of Bennett's views on inflammation were made subjects of criticism by Professor Greenfield, who held them up as an example for the warning of others, lest they might be induced to assign importance to hypothesis as these had received the confirmation afforded by successful application as theoretical explanations of observed phenomena. He admitted the necessity of occasionally accepting unproven views as guides to conclusions, but insisted that they must always be regarded as simply provisional; and from a pathological standpoint it cannot be said that the caution thus imparted was either uncalled for or undesirable.

A further explanation of the reason why pathological studies necessitated so much greater provision in the way of laboratory arrangements &c. now, than formerly; vindication of the experimental method of investigation, and defence of the lecture system of instruction, when accompanied by practical work, were the remaining subjects dwelt on in the address, which may safely be ranked among the more useful contributions to this description of literature.

To the midwifery class Professor Simpson advocated the foundation of a class of gynecology in the university, and explained the resources of the school for thorough and practical teaching of the science and art of obstetrics. He referred to the recent creation of two scholarships, in gynecology and midwifery respectively, which are now open for competition among members of his classes.

Professor Grainger Stewart's opening lecture to the class of practice of medicine was mainly devoted to a consideration of Koch's discovery of tubercle bacillus, and the practical benefits to be expected as its consequences. Several important improvements were announced as having been made in the arrangements for practical teaching in connection with the use of the ophthalmoscope and laryngoscope, by which the study of eye and throat diseases will be much facilitated and rendered of more enduring value.

At Glasgow an important occurrence took place in connection with the Royal Infirmary School of Medicine, an extensive block of new buildings erected for its accommodation having been opened for use. The introductory address on this occasion was delivered by the Lord Provost of the city, who dwelt on the usefulness of the school as an aid in carrying on the infirmary practice. The school, he declared, had been rendered a necessity to the hospital, especially after the severance of the bond uniting it with the university; and the success which had followed the institution of the school was expressed by the fact that, without straining the resources of the infirmary in any way, and for its own purposes, the school had been enabled to remove to larger and more commodious premises. Deprecating any unseemly rivalry the Lord Provost insisted that the Royal Infirmary School and the University and Western Infirmary School could each find work to do and be useful. On the subject of remuneration for professional services the Lord Provost was very explicit, and in this connection it is pleasant to be able to record such utterances as the following from a lay orator: "I would hail

the advent of the time when the practice was general of paying—and paying handsomely—our physicians for guidance and advice in keeping us well, rather than, as now, for their attendance upon us when we are sick. But I frankly admit that neither county nor town authorities have, by the salaries they give to their health officers, shown that they estimate as they ought the highly valuable services which these gentlemen render; and so it is probably too much to expect that the medical profession, which gives of its services so much gratuitously already, should be very forward in making a new departure in the direction I have indicated."

At the Western Medical School of Glasgow Dr. McVail delivered the opening address, the principal topic touched being the relations of the School to the University, and the injustice done it by the latter body in refusing to accept certificates of attendance at local extra-mural teachers' classes. He sketched the history of Glasgow University as a centre of medicine very much to its disadvantage, and demonstrated the illiberal spirit in which it regarded the admirable work done by the many illustrious teachers at Glasgow unconnected with University chairs. He pointed out the constant and lengthened struggles against monopoly on the part of extra-mural institutions, and concluded an instructive and eloquent address by appealing against the narrow-minded, illiberal spirit being permitted to hamper the progress of medicine.

In most respects, the formalities observed at the commencement of a new academical year are the same in Scotland as in England, addresses being deemed an essential institution in this connection. Whatever views may be held, therefore, respecting the expediency of this mode of commencing a fresh period of activity, must apply equally in the two kingdoms, unless there is anything, hitherto undiscovered, to make different opinions applicable in the two cases. Apart, however, from such considerations, the addresses delivered before the Scotch students of medicine contain a fund of valuable information and advice, and we trust they may prove to be initiatory to a year's performance equivalent to the merit they display.

THE CASE STATED AGAINST THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES BY THE ATTENDING PHYSICIAN.

—No. IV.

WE have assumed that concealment of infective disease is the natural result of stringent sanitation, and we think it needs no proof to satisfy any one that the more actively disinfection of premises and isolation of patients are carried out the greater is the probability that, to avoid these unpleasantnesses, disease will be concealed. We say, advisedly, that in towns in which compulsory notification is the rule, that concealment does take place to a very serious extent, and, indeed, medical officers do not, as a rule, dispute its existence. At Bolton last year there was a tremendous increase of typhoid following quick upon the active steps taken by the medical officer of health to carry off to hospital all infected

patients whom he could discover. The only evidence attainable, however, would be that to be gathered from the death certificates. A certain percentage of the dead in every town are, of course, registered as having died without the ministrations of any qualified medical practitioner, they having received any medical advice which they cared to take from the neighbouring chemist, or some old woman or other quack in whom they had confidence. It would be interesting to know whether, in compulsory notification towns, the percentage of deaths without medical attendance is or is not greater than in other similarly situated towns not under notification compulsion. If it appeared that the proportion of such cases was increased by notification, then we think our contention that the physician is excluded with a view to concealment would be proved. We invite medical officers of health to test our argument in this way. And, *à propos* of death certificates, we may take this occasion to point out how fallacious is the argument that, inasmuch as physicians must, and do, notify deaths, there is no hardship in requiring them to notify infection. Why the true facts of death certifying prove conclusively our case against the proposal that physicians should be compelled to notify, for everyone knows that death certificates are, in many cases, utterly fallacious and misleading, and are so because it is desired to conceal the true cause of death. If we were to estimate the prevalence of syphilis or of *delirium tremens* from the Registrar-General's returns, we should at once conclude either that those were almost unknown diseases, or that they were seldom or never fatal, for we very rarely should find a death certified under either of these names, but we should find plenty of non-descriptive cases, such as "general debility," "irritation of the spine," and so forth—so catalogued for the purpose of concealing diseases of which the deceased's family might naturally be ashamed. In the same way it is found that in notification towns infective diseases are suspiciously rare. We have, it is true, many deaths from "sore throat," "dropsy," "blood-poisoning," or "convulsions," which, if the truth were known, would turn out to be scarlatina or small-pox. This is an admitted fact, and it proves that, as you cannot punish anyone for attributing a death to a mere symptom of the disease, and ignoring the disease itself, it is therefore nonsensical to enact a law to impose such punishment.

It is, as our readers will have observed, our contention that compulsory notification of infectious disease by the attending physician, means exclusion of the physician until the case has assumed such gravity that exclusion is no longer possible—that such exclusion means the neglect of those sanitary precautions which are now effected by the advice given by the doctor—that the neglect of those precautions means dissemination of disease and, *ergo*—that compulsory notification by the physician, so far from being a protective measure, is calculated to aggravate the evils which it is intended to remedy. The force of this line of argument rests altogether upon the practicability of enforcing the law against those who neglect the notification duty imposed upon them.

IMPRACTICABILITY OF THE PROPOSED LAW.

If it were possible readily to detect and punish the physician who neglected to send in his report to the sanitary

authority, the proposed law would at least have the merit of being a good working measure, however opinions might differ as to its being a just one, but practicability is the quality which the bill for notification by the doctor totally lacks. Suppose such general law to be enacted to-morrow, it would be simply waste paper if the medical profession were determined not to comply with it, and it would be worse than useless if it were carried into effect even by a majority of the profession, and neglected by any considerable minority. A little consideration of the wording of the proposed law, and the indefiniteness of the duty to be imposed on the physician, will show this. It is proposed by Mr. Hastings' bill that "any medical practitioner attending, or requested to visit and attend any inmate . . . suffering from small-pox, &c., . . . shall immediately on becoming aware of the nature of the disease from which such inmate is suffering, fill up, &c., &c., &c.," and by a subsequent section, "any person neglecting to transmit any notice required by the Act shall be liable to a penalty of £5." Be it observed that under this law no physician would be responsible to notify unless he was "attending or requested to visit and attend," so that any medical man who might come to the knowledge of a case of infection without being actually called to take charge of the person suffering from the disease, might at once free himself from liability by pleading that he was not in attendance, nor requested to visit the sick person, and, on the other hand, the custodian of such a patient might obtain advice and information, and at the same time, evade notification by the physician, by bringing him to the house, on any pretext, and carefully informing him that he was not to consider himself in charge of the infected case.

Again, let it be noted, that the physician is responsible to notify only "on becoming aware of the nature of the disease from which such inmate is suffering," an arbitrary date which never could be made available in any prosecution. It is notorious that, in many cases, the most skilled physician can have no certainty of the nature of the disease, until it has reached an advanced stage, because, very commonly the indicative eruptions and other physical signs are absent, and this uncertainty is, in most cases, sufficient to afford a fair excuse to the physician if he is challenged for the omission to notify. An illustration of the truth of this statement appears in the *British Medical Journal* (October 28), where we find it recorded by the Medical Officer of Health for Gloucestershire that he had caused several patients to be remitted to the infectious hospital, though at the same time he asks himself, "Was the outbreak small-pox at all?" Every physician knows that there are numerous cases of—presumably—infectious disease which never reach a stage at which there can be a certainty as to what the disease is, and all such cases, though they are as completely centres of infection as any other cases, must be omitted from notification, especially if the patient objects to be notified, because no physician could be expected to take the responsibility of declaring the house tainted unless he was positive in his opinion. The proposed law must, therefore, be partial in its operation, even though the physician should be quite willing to perform the duty.

But there is a much more serious objection than this to the working of the proposed law, grounded upon the fact that, if the physician does not please to notify, no power on earth can make him do so, and no Act of Parliament can punish him for omitting to do so. This fact will be realised when we remind our readers that the diagnosis of an infectious disease is a simple matter of professional opinion, and no man can be prosecuted or punished for making an incorrect diagnosis, or forming an inaccurate opinion.

A physician may be called to see a scarlatinal patient; he may recognise the disease, but he may not choose to annoy his patient by notifying, or he may intend to send the necessary notice to the sanitary authority, but may neglect or forget to do so. Perhaps the patient dies, and the knowledge of the case comes indirectly to the medical officer of health. How is the physician to be punished? It is true he may be summoned to the police court and charged with an offence against the proposed law; but it is also true that no evidence can possibly be produced which can convict him. He has only to say that he did not recognise the disease as infectious, or boldly assert that it was a case of nettle rash, or some other non-infectious disease, and he *must* be discharged free. True, he may be called an ignoramus by the medical officer of health for not recognising such obvious symptoms, but no further penalty can be inflicted on him, seeing that stupidity or ignorance of the symptoms of disease are not crimes punishable by law. Therefore, we say that the proposed law would be altogether impotent as regards the very class of practitioners whom it is intended to reach. Experience proves that it is so. In the seventeen towns in which notification by the physician has been in force for years past, not a single successful prosecution has been effected, though the omission to notify has been palpable in every one of them. In Edinburgh and in Bolton prosecutions have been successfully carried out, but on these occasions the recalcitrant physician had pleaded simply either that he did not know the law, or that he objected to it, neither of which pleas were, legally, of any avail. If they had excused themselves on the ground that the case was not one of infective fever, or that they did not recognise it up to the date when they were summoned, or that they were not *in attendance* on the infected patient, they would, as a matter of course, have got off scot free.

(To be continued.)

MEDICAL ADVERTISING.

THE following resolution was adopted last week by the Fellows of the King and Queen's College of Physicians in Ireland:—

"That the system of extensively advertising medical work, and the custom of giving, whether for publication or not, laudatory certificates of medicinal or other preparations, or of medical or surgical appliances, is misleading to the public, derogatory to the dignity of the profession, and contrary to the traditions of the King and Queen's College of Physicians."

This is an important declaration, and with its spirit and intention we cordially sympathise. The system of advertising by medical men, both in England and Ireland, has

reached an extension which is simply disreputable, and we agree that it is the proper function of the Irish College of Physicians to fulminate against that method of doing business. But it seems to us that the resolution is not well put, and that it goes beyond the censorship which the College is entitled to exercise. There is no objection, nor has any college a right to object to the extensive advertising of a medical work, so long as that advertising is done for the legitimate purpose of selling the book. Again, to express one's opinion about medicinal preparations or appliances is reasonable and proper, so long as the opinion is expressed *bona fide*, and for no other purpose save the approval or disapproval of an article of disputed merit. The discredit attaching to the prevalent advertising system is in the gross, obviously self-interested, and most disreputable abuse of advertising.

As regards books, the usual thing is for one obscure practitioner to steal some one else's ideas and labours, and paraphrase them in a shilling pamphlet. He then advertises the contemptible result of his literary fraud in the most prominent column of every newspaper which has numerous readers, and goes on reprinting the pamphlet and reiterating the advertisement as long as it pays him to do so.

In London many authors intensify their own importance by heading the advertisement in capital letters—"Dr. Koffnomore on Chest Diseases," or "Mr. Immediate Splitter on Urinary and Venereal Affections," or "How to Lie-in without Pain or Danger," Just published, price one shilling, a complete treatise on all the Diseases of Women and Children, by Dr. R. Hunter, &c., &c., &c. The reflex laudation certificate by which a medical man, ravenous for publicity, puffs himself in seeming to puff some one's wares is equally objectionable, and its discreditable purpose quite as manifest.

Any one can see the superficial object of these advertisements, and, while it is quite impossible to make any general rule against such quackery, it is quite easy to detect and punish the offence in the individual. Therefore, we counsel a little more courage and candour in dealing with the matter, and we advise that, when any Licentiate of the College offends in this way, the Fellows of the Irish College of Physicians shall show the necessary *fortiter in re*, and put him personally under foot. Vague resolutions such as that we have quoted above are unjust towards the great majority of the profession, and impotent towards the few who are driving the objectionable trade.

Let us have the strength of mind to make one example of an offender, and that example will be all-sufficient as a professional depurative.

AMERICAN DIPLOMAS.

WE have many times warned the profession against the dangers which are involved in the proposed legislation for recognition of foreign and colonial diplomas as qualifications to practice in Great Britain, but we have failed, as yet, to arouse attention to the subject. The admission of foreign diplomates to the same footing as British licentiates seems to be generally regarded as a matter of insignificant detail, and even the Royal Commission on the Medical Acts did not trouble itself

much with the proposition. Nevertheless, we are of opinion that, if the proposed law should ever be enacted by which the General Medical Council would have power to admit the diplomas of any foreign college, with or without inquiring as to their sufficiency, the result would be most disastrous to the public as well as to our profession. There are many Continental and a few American and Colonial licensing institutions which might be admitted within the pale without hesitation, but they are numerically insignificant in comparison to the multitude of "diploma mills" in America and elsewhere, "run," as the phrase goes, by needy, avaricious, unprincipled, and obscure medical men. As an illustration we cull the following paragraph from the *Philadelphia Medical Reporter*, speaking of such institutions, the *Reporter* says :—

"The history of all such enterprises is a long list of jealousies and backbiting, degrading competition for students, wretchedly superficial instruction, deficient anatomical and clinical material, servility in lecturing, a sham of an examination, and a lot of grossly incompetent young men turned out to prey on the community as doctors. If by accident an honest man is on the faculty and exposes this miserable history, then comes a scene of slander and recrimination, which stains the whole profession with its inkiness.

"A lamentable example of the kind has been recently shown by the Columbus (Ohio) Medical College. It graduated a man after *three weeks* attending at lectures, and in the face of the remonstrance of at least one member of the faculty. The matter leaked out through the latter, and a vile anonymous attack upon him was made by another member of the faculty, in the columns of a *Sunday paper*, written at his request, it appears, by some attorney of the size of that sort of work. This happened at the Columbus Medical College. But it is a great mistake to suppose that that college is particularly to blame in this matter. It has been called a 'disreputable establishment,' but it is not a whit more disreputable than a dozen other colleges, East and West, that could be named. It did what almost all poor colleges, scrambling for a foothold, must do. Such colleges cannot afford to repel matriculants by getting the reputation of being severe. Then there are always in this country a large body of men who are poor and ill-educated, and yet who want the degree of M.D. These are always on the look-out where they can obtain it at the least expenditure of time, brains, and money."

What we desire to impress upon medical reformers is that, in this matter, as little power as is possible should be given to the Medical Council. That body has shown by its dealings with preliminary examination what course it would be likely to pursue if empowered to confer recognition on any foreign institutions it might please to accept. It has given its official recognition to dozens of preliminary examinations of which it had nothing but the flimsiest *ex parte* information, and without taking the least trouble to ascertain the sufficiency of the test, and we apprehend that the good-natured and easy-going old gentlemen who constitute the Council would be very unlikely to trouble themselves with an inquiry about the educational status

of the Columbus College, or any other such institutions, and very unwilling to refuse recognition without evidence against it.

Notes on Current Topics.

The Medical Union Society.

THE formation of a Medical Union Society is announced, with premises at No. 10 Adelphi Terrace, Strand. This Society which has been incubating for a considerable time past, is designed to unite together the whole body of medical students and junior practitioners, and will undoubtedly supply a want which has long and loudly been expressed. The Union commences existence under most favourable auspices, the executive committee including amongst its members Dr. Danford Thomas, Coroner for central Middlesex, Dr. Palfrey, Dr. Forbes Winslow, &c.; and the rooms engaged for its use are of ample size, and well adapted to the purpose held in view. The Society is formed on the model of the Oxford and Cambridge Unions, and while possessing usual club accommodation, it will make this subservient to the more important work of organising and elevating the class of students. Being designed in the interests of these chiefly, the Union will be open daily from four to eleven p.m., in order that it may not be converted to a distraction from work during the regular hours of hospital attendance; and weekly meetings for debating will be held alternately with *soirées*. The rooms of the Society will be open for the use of members on and after November 15th inst., the hon. secretaries are Messrs. Wade and Greenwood, to whom names and subscriptions (one guinea per annum), may be sent forthwith. The Society's rooms may be inspected by intending members daily, between one and three, until the 15th.

West London Medico-Chirurgical Society.

THE second ordinary meeting of this young but flourishing Society was held at the West London Hospital, on Friday evening, and was devoted to the exhibition and discussion of cases and specimens. Dr. Hart Vinen, the President, took the chair. Mr. Percy Potter showed a case of considerable interest. His patient, a man of middle age, fell upon his head three years ago, and produced what was called a "dislocation of the neck." At the present time there was a protuberance at the back of the cervical region, and the nature of this protuberance gave rise to much speculation. Mr. Keetley pointed out that the case was almost unique in the annals of surgery, for there had evidently been a crushing of the bodies of the cervical vertebrae, similar to what takes place in Pott's curvature in the dorsal region, and the wonder was that the man was now alive. Some interesting cases of locomotor ataxy, associated with Charcot's joint affection, were shown by Dr. Atkinson, Mr. Keetley, and Mr. Edwardes, and elicited from Dr. Thudichum a most exhaustive description of the microscopical changes which he had found in the spinal cord in this disease. Mr. Lunn exhibited a brain from a patient who had had several hemiplegic attacks affecting different regions and at various times. The brain exhibited a cyst in the corpus striatum, and hæmorrhages in various

parts. Dr. Clippingdale described a case of spontaneous dislocation of the sternal end of the clavicle, secondary to lateral curvature. The patient he had been unable to induce to attend. Mr. Keetley and Dr. Pearson exhibited a man with oedema of the left leg. Dr. Pearson diagnosed embolism of the femoral artery. This seemed to be the general opinion of those present, but how the embolism had been produced was a mystery. Votes of thanks were accorded to those who had brought forward cases, and the President eulogised the valuable remarks made by Dr. Thudichum upon the chemical changes in locomotor ataxy.

"Quain's Dictionary of Medicine."

AN event of considerable importance to medical literature is the publication of the Dictionary of Medicine edited by Dr. Quain. This is the most considerable and important work of the kind issued since the well-known volumes of Dr. Copland, and will necessarily become a permanent work of reference to the profession. It is necessarily a bulky book, the whole work being included in one large volume consisting of over eighteen hundred closely-printed pages of two columns each. In its preparation Dr. Quain has received assistance from a large number of the best-known authorities in medicine, and each article is signed by the author, thus adding considerably to the weight carried by the opinions expressed in the work. As a reflection of the present state of medical knowledge in this country, it is incalculably the most important of all recent publications; and for all purposes of information it must henceforth take a leading place in the list of reference books in constant use by practitioners. Of the arrangement and contents we shall speak at length in an early number; at present it is impossible to do more than announce that it is ready, a fact, as we have hinted, of more than usual importance from a literary point of view.

Photography for Invalids.

LAST week a studio of imposing and elegant dimensions, in the so-called "Queen Anne style," was opened in London at 263 Oxford Street, by Mr. Barraud, the artist who designed and executed the picture of the late International Medical Congress. As Mr. Barraud's work lies so much with members of the medical profession and their patients, he has purposely introduced a patent lift by which invalids and others who object to the ascent of the customary long flights of stairs found at the ordinary studios, can now be lifted noiselessly and without the slightest effort on their part from the entrance to the top of the building, where photography can be carried on in a pure light, and with all the modern artistic surroundings. At the formal opening of the premises on Thursday last, a crowd of critics from the medical, artistic, and literary professions assembled to examine and congratulate Mr. Barraud on his achievements, the large picture of the Medical Congress coming in for very favourable comment.

DR. W. A. ANDERSON, whose sudden death at his residence at Uxbridge is reported, was Assistant-Surgeon to the Royal Naval Hospital, Plymouth, and a Justice of the Peace for Middlesex. He was greatly respected both in his public and his private capacity.

The Railway Catastrophe.

THE painful accident whereby Mr. John Findlay Arthur, M.B., M.C. Aberdeen, recently met his death on the Midland Railway, has excited the universal sympathy, not only of every medical man to whom the sad occurrence is familiar, but among the general population of the country. The unfortunate deceased was, at the time of the accident, *en route* for his parents' residence, having just returned after a lengthened residence in Ceylon. By some means, not explained satisfactorily at the inquest, the sleeping berth of a Pullman car in which Mr. Arthur was travelling caught fire, and he alone of all the passengers in it failed to make his escape. He had intimated his intention of reaching Aberdeen by the train he was in, and his friends were awaiting his arrival at the station there, when information of the terrible misfortune they had sustained was communicated to them. The grief of the family commands the deepest sympathy of the profession, which in Mr. Arthur loses a most promising member, and one who had already proved his claim to be regarded for many admirable qualities. He was a successful student at Aberdeen, where many friends retain kindest recollections of his genial, hearty temperament, and unusually vigorous physique. As a district medical officer under the Ceylon Government, he has recommended himself to favourable notice by his devotion to work and energetic performance of the duties attaching to his post. His loss will be experienced as a blow equally abroad and at home.

Dr. Abrath and the North-Eastern Railway.

IN the Queen's Bench Division of the High Court of Justice, on Saturday last, Sir Hardinge Giffard, Q.C., with whom was Mr. McClymont, moved to set aside the verdict in the case of *Abrath v. The North-Eastern Railway Company*, on the ground that the verdict was against evidence, and that there was misdirection on the part of the learned judge who tried the case at Durham. The facts of the case are by this time so well known that we need scarcely make reference to them. It will be remembered that a Mr. McMann, who was injured in a railway collision on the Company's line, brought an action for damages, but just before going into court, and on the advice of the counsel engaged for the Company, and of their medical men, the North-Eastern directors decided to compromise the action by paying the plaintiff £950. At the expiration of a year or more the Company thought proper to charge Dr. Abrath, McMann's medical attendant, together with McMann, with having conspired to cheat them. In this, however, the Company signally failed. Dr. Abrath then brought his action against the Railway Company for the malicious prosecution, but also failed to establish his case, chiefly for the reasons assigned by Sir H. Giffard. On the conclusion of the learned counsel's argument, the Court granted a rule *nisi*. The case will now be tried in London, and by a special jury.

DR. JAMES ANDERSON, Assistant-Physician to the Victoria Park Chest Hospital, Junior Demonstrator of Anatomy in the London Hospital, has been appointed Examiner in Anatomy at the Royal College of Physicians of London.

Death of Dr. Seguin's Family.

DR. EDWARD SEGUIN, who is almost as well known on this side the Atlantic as in America, has sustained a fearful affliction in the loss of his wife and three young children under circumstances of the most mournful description. In the absence of her husband Mrs. Seguin had engaged her children, two boys and a girl, the eldest but six years old, in a nursery game, during which they were blindfolded, and the hands of each bound behind the back. While thus powerless to interfere with her design, the unfortunate mother shot them severally through the head, and subsequently committed suicide herself. When discovered all four were dead, and the shock experienced by Dr. Seguin when the true state of the case was apparent was of the most dreadful description. Although his wife had exhibited occasional symptoms of despondency, it had never been supposed that anything seriously affecting her mind had taken place; and the affectionate terms on which the whole family lived precluded any possibility of suspicion of the true state of affairs. The occurrence is especially distressing on account of the insidiousness of the malady which led to it, since Dr. Seguin, as an experienced neurologist of almost world-wide renown, had not been led to think his wife liable to an outburst of homicidal and suicidal mania such as she must have been suffering from at the time the tragedy was committed. We cannot do more now than offer the deepest sympathy of the profession on this side with our American brother in his sore affliction.

The Parkes Museum.

THE first annual general meeting of the Parkes Museum was held on Saturday, October 28th, in the new premises recently acquired in Margaret Street, Regent Street. Captain Douglas Galton, C.B., F.R.S., occupied the chair, and was supported by Mr. George Godwin, F.R.S.; Professor De Chaumont, F.R.S.; Mr. Thomas Twining; Professor John Marshall, F.R.S.; Mr. C. Robins; Mr. Rogers Field, C.E.; Professor Corfield, Mr. Davenport Hill, Professor Poore, and other gentlemen interested in the progress of the science and practice of hygiene.

The secretary (Mr. Mark H. Judge) having read the notice convening the meeting, it was proposed by Mr. Thomas Twining, and seconded by Mr. George Godwin, that H.R.H. Prince Leopold, Duke of Albany, whose consent had previously been obtained, should be elected President of the Museum.

On the motion of Dr. G. V. Poore, the following noblemen, gentlemen, and ladies, whose consent had previously been obtained, were elected Vice-Presidents of the Museum:—The Duke of Northumberland, the Duke of Westminster, K.G., the Earl of Derby, the Earl of Fortescue, the Baroness Burdett-Coutts, the Right Hon. Sir Richard A. Cross, M.P., Sir Joseph Fayrer, K.C.S.I., Mr. Edwin Chadwick, C.B., Professor Huxley, Miss Florence Nightingale, Mr. Robert Rawlinson, C.B., and Professor Tyndall.

Dr. Dawson Williams moved that the following gentlemen, who had acted as the Provisional Council, should be elected as the Council:—Captain Douglas Galton, F.R.S.,

vice-chairman; Professor Berkeley Hill, M.B., F.R.C.S., 55 Wimpole Street, W., treasurer; Professor W. H. Corfield, M.A., M.D.; Mr. Rogers Field, C.E.; Mr. George Godwin, F.R.S.; Professor William R. Gowers, M.D.; Professor T. Hayter Lewis, F.S.A.; Professor John Marshall, F.R.S.; Mr. Charles Henry Parkes; Professor J. Russell Reynolds, M.D., F.R.S.; Mr. Edward C. Robins, F.R.I.B.A.; Dr. Edward H. Sieveking; Professor T. Roger Smith, F.R.I.B.A.; Dr. J. Charles Steele; Mr. Thomas Twining; Mr. Alfred Waterhouse, A.R.A.; Dr. Dawson Williams, hon. sec.

The motion was carried unanimously.

Professor De Chaumont proposed a vote of thanks to Captain Douglas Galton for presiding.

The Chairman, in the course of his reply, remarked that the alterations necessary to adapt the premises the entrance to which was at 74A Margaret Street, to the purposes of the Museum, were in progress. It was hoped that the collection would be ready to be opened to the public with the new year; but the re-arrangement of the museum, which had been confided to a competent committee, was a somewhat onerous duty. Every effort would be made to render the collection thoroughly representative of all that was best in the application of sound sanitary principles to practical work. The museum was to be, he hoped, a great educational centre, and he was glad to be able to announce that already one important piece of work was in hand. Professor Corfield and Mr. Rogers Field had prepared an admirable scheme of drainage for the museum buildings, and had so arranged it that every important point would be open to inspection, and thus available for purposes of instruction. Mr. Rogers Field had generously offered to himself defray all the cost of the new system. Mr. Twining had presented the museum with a valuable collection illustrating the variety of substances which could be used as food, and he was at present engaged in classifying the specimens and arranging them in suitable cases.

A vote of thanks to Mr. Rogers Field for his munificent offer was unanimously adopted. The meeting then adjourned.

It may be recollected that soon after the death of Dr. E. A. Parkes (Professor of Hygiene at the Army Medical School, Netley), which took place in the midst of labours devoted to the development of sanitary science, it was determined at a meeting of his friends and admirers to do honour to his memory by establishing a museum to illustrate that knowledge which Dr. Parkes had done so much to develop. The museum was publicly opened by the Secretary of State for the Home Department in 1879, and has thenceforth been the means of instructing a large number of persons in sanitary knowledge. In 1881, under the patronage of H.R.H. the Duke of Edinburgh, the committee inaugurated the first International Medical and Sanitary Exhibition, which was opened at South Kensington by the Lord President of the Council. This exhibition remained open for four weeks, and was visited by 24,333 persons. At its close, 258 of the exhibitors received awards. The museum was incorporated in June, 1882. It was found necessary to close the museum in July, 1882, in consequence of the Council of University College requiring the gallery for the purposes of the College; but now

premises have been secured in Margaret Street, Cavendish Square, in which the museum will be re-opened as soon as the alterations and additions now in progress are completed. The new museum will consist of a central hall, library, and corridors, all lighted from the top, and well suited for exhibition purposes; and meetings, demonstrations, and lectures, which have hitherto been only occasional, will, on the re-opening of the museum, become a permanent feature of the institution. There is a fair prospect that besides directly subserving the studies of medical men, architects, engineers, and others on whose special attainments the public health so largely depends, the Parkes Museum will ultimately, by methodically displaying in the most convenient manner select illustrations of every department of hygiene, acquire national interest as a standard repertory of the latest sanitary improvements, and as a pattern for facilitating the formation of similar museums in provincial towns.

Medical Work in the Holy Land.

We are informed that the Committee of the Jerusalem Hospice Fund has made arrangements for opening immediately a temporary Dispensary at Jerusalem, pending the erection of the building a site for which has been granted by the Sultan to the Order of St. John. Dr. J. C. Waddell, who has had special experience in ophthalmia, has left England for Jerusalem, to commence work. Letters have lately been received from Mrs. Burton, the well-known authoress, Sir Austin Layard, and others, testifying to the fearful sufferings caused by this disease. Funds are needed for the work, and subscriptions will be gladly received by Lady Lechmere, 13 Bolton Row, W., and Captain Dallas, treasurer, St. John's Gate, Clerkenwell, E.C.

The Medical Department and the Real Culpit.

It would ill-become any one, whatever may be his views, to attempt at such a time to detract from the glories, individual and collective, which await those returning from the successful suppression of the "military rebellion against the Khedive;" but it equally behoves any who are lovers of fair play to strive, amid the din of applause, to gain a hearing for the claims of those whose departmental title has been made the "newspaper poster" upon which to flaunt the sensational breakdown of the campaign.

"Collapse of the Medical Department" is the red herring drawn across the true scent of the unpreparedness which marks the openings of all our wars.

While, in time of peace, the regulation military adviser and the obedient military press raise their hands and voices against such demoralising innovations as the entrusting of medical officers with the command of a few orderlies, or the independent control of an hospital, and loudly proclaim that the charge of horses and waggon would cause the jingling of their spurs to drown all medical knowledge and professional skill, yet, when war breaks out, medical officers are transported to the seat of operations with their pocket cases only, and are, by dishonest silence, held responsible to the public for the sufficient supply of hospital equipment and medical comforts over

the transport, of which they have exactly the same control as they have over the carriage of shot and shell, which invariably take precedence of medicines. And while the Commissariat and Ordnance Departments are being complimented on the precision and rapidity with which they have supplied and carried the munitions of war, having used for that purpose the means of transport which should have brought forward the medical necessities, the Medical Department is held up to scorn for having broken down in a duty over which they had absolutely no power.

The Mastership of the Rotundo Hospital.

THE seven years during which the Master of the Rotundo holds office having expired last week, Dr. Atthill retires from that office. His Mastership has been marked by the energy displayed by him in advancing the interests of the hospital and improving the teaching therein. The finances of the institution were, we believe, in a very unhappy condition when he assumed office, but by indefatigable effort he succeeded in raising £3,000, and now leaves the hospital substantially at the right side of its bank account. Many most important changes and much-needed reforms and structural improvements of the hospital were effected during Dr. Atthill's Mastership, and on his retirement from office the Governors adopted unanimously the following resolution, proposed by R. W. Shekleton, Esq., Q.C., and seconded by Charles Cobbe, Esq., D.L. :—

"Resolved,—That we, the Board of Governors of the Rotundo Lying-in Hospital, on Dr. Atthill's retirement this day from the office of Master of our Hospital, hereby tender him our very best thanks for the great attention, care, and distinguished skill he has given and displayed in said office during the last seven years; and we most warmly congratulate him on the high state of efficiency in which he leaves the hospital, and on the marked success he has achieved in maintaining it as a medical school equal, if not superior, to any other of its class in Europe."

Dr. Macan, Gynæcologist to the City of Dublin Hospital, succeeds Dr. Atthill, and brings to the Mastership a very high character for a thorough knowledge of his speciality and remarkable operative skill. Dr. Purefoy and Dr. W. J. Smyly were also mentioned as candidates, but they were not formally proposed. The Assistant-Masters retain their offices as heretofore.

The Poor-law Medical Officers' Superannuation Act in the Monmouth Union.

OUR contemporary the *Dean Forest Guardian*, in its issue of the 27th ult., reports that at a meeting of the Monmouth board of guardians, held on the preceding Saturday, Mr. J. T. Adams, one of the guardians, in pursuance of notice, moved a resolution to the effect that the board should give to Mr. John Hatton, who had been incapacitated from attendance to his duty by two attacks of paralysis, superannuation allowance to the extent of £50 a year. In the course of an unusually able, eloquent, and exhaustive speech, Mr. Adams pointed out what were the intentions of the Legislature in passing the Medical Officers' Superannuation Act. He then proceeded to show that Mr. Hatton had held office for 36 years, at a very low stipend; that during that very lengthened period no complaint had ever been made against this gentleman;

and that he was now, at 66 years of age, paralysed, and in circumstances such as to require the grant he asked the board to allow. The resolution having been duly seconded by Mr. Hough, who confirmed the statements of the preceding speaker, and having been supported from the chair, was met by an amendment from Mr. Dampedo, who, after urging the various platitudes trotted out on these occasions, moved that the grant should not exceed £26 per annum. This, after some discussion, was adopted by a majority of 9 in a meeting of 35 guardians.

Whilst sympathising with Mr. Hatton in the smallness of the allowance accorded, and condemning the niggard hands which have doled out to him this miserable pittance, we would point out that, small as it is, this board has been more considerate than the Petersfield board of guardians, who, after a service extending over 40 years, refused Mr. George Pink, who had reached the patriarchal age of 80 years, any superannuation at all; and the case of a medical officer in a Somersetshire union, whose name we cannot recall, who was not only denied that which the Legislature intended, but was insolently offered in his old age and indigence an order for the workhouse.

In bringing this comment to a close, we would express our opinion that much of the ill-treatment which the profession, and notably its Poor-law section, receives is due to the want of unanimity so patent among them. When will the profession learn that union is strength? We feel it is far from the knowledge of it at present.

DR. GEORGE H. KIDD, of Dublin, has, we learn, been elected an Honorary Fellow of the Edinburgh Obstetrical Society, an honour which he shares with Dr. Barnes, of London.

THERE were fewer deaths last week in Paris from the typhoid epidemic than the previous week, 173 being reported, against 244 and 250 the two previous weeks; in other respects the numbers are nearly the same.

A LIVELY contention as to the presence of typhoid at Ventnor is going on in the daily press between the medical practitioners of the town and visitors who have flown from it. We need scarcely add that what one side represents as white the other contends is black. Probably the truth lies between: there have been two or three cases, and these will occasionally happen in every town, but the fussy interference and newspaper correspondence are both uncalled-for and unjust.

WE understand that the action against our contemporary the *Lancet* by the Corporation of Brighton, has been withdrawn, in consequence of that journal having published in *extenso* the report of Dr. Richardson on the sanitary condition of Brighton, in which he says he "found nothing whatever that would lead him to believe in the occurrence of any special disease or mortality from bad drainage." In the same number our contemporary publishes an apologetic "leader," and the matter may now be considered at an end. The *Lancet's* "Special Commissioner" will have to be a little more careful in future.

WE understand that the Lord Chancellor has, on the recommendation of the Duke of Wellington as Lord Lieutenant, appointed Dr. Alfred Meadows, of Poyle Manor, Colnbrook, and George Street, Hanover Square, a Justice of the Peace for the County of Middlesex and the City and Liberty of Westminster.

WE understand that the following officers of the Army Medical Department are under orders to embark for Egypt at an early date:—Surgeons-Major B. J. Jazdowski, T. S. Comyn, R. Anderson, W. D. Wilson; Surgeons H. M. Reid, F. G. Jenckin, H. O. Stuart, W. H. P. Lewis, F. H. Trehern, W. Dick. Most of the above only recently arrived home from Egypt.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Bristol, 16; Leicester, Edinburgh, Salford 17; Wolverhampton, Brighton, Hull 18; Newcastle-on-Tyne, London 19; Bolton, Birmingham 20; Dublin, Nottingham, Portsmouth, Bradford, Sheffield, Derby 22; Blackburn, Huddersfield, Halifax, Manchester 23; Plymouth, Cardiff 24; Glasgow, Liverpool 25; Leeds, Norwich 26; Birkenhead 28; Oldham 29; Sunderland, 32; Preston 34.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 23, Bombay 27, Madras 34; Paris 25; Geneva 21; Brussels 16; Amsterdam 23; Rotterdam 19; The Hague 21; Stockholm 19; Christiania 14; St. Petersburg 39; Berlin 24; Hamburg 20; Dresden 23, Breslau 25, Munich 26, Vienna 22, Prague 29, Trieste 24; Rome 20; Venice 19; New York 24, Brooklyn 21, Philadelphia 20, and Baltimore 28.

THE annual death-rates per 1,000 in the larger towns last week, from diseases of the zymotic class, were:—From scarlet fever, 1.2 in Leeds and Cardiff, 1.4 in Oldham, and 2.2 in Sunderland; from measles, 1.6 in Sheffield, 1.8 in Cardiff, and 7.9 in Sunderland; from whooping-cough, 2.1 in Preston and 2.4 in Birkenhead; and from "fever," 1.6 in Portsmouth, and 1.8 in Leeds and Birkenhead. The 29 deaths from diphtheria included 12 in Glasgow, 9 in London, 2 in Liverpool, 2 in Edinburgh, and 2 in Sheffield. Small-pox caused 3 deaths in London and 2 in Newcastle-upon-Tyne.

AT the opening of the winter session of the Berlin Medical Society, Herr Bardeleben in the chair, an announcement was made of the formal presentation of the bust of the retiring President of the Society, Herr Langenbeck, to the Royal University Klinik. The chairman thanked the Society for the honour they had shown to their distinguished President in defraying the cost of the work. At a subsequent meeting Herr Virchow was elected President in the place of Langenbeck. The three Vice-Presidents chosen were Herren Bardeleben, Henoch, and Siegmund.

The Irish Academy of Medicine.

THE project of an Irish Academy of Medicine, which seems to have lain dormant from the time Dr. Lyons advocated it in 1851, until a few months ago, when the question was again brought to the front through the agency of the Council of the Pathological Society, is now, we are happy to say, assuming a practical form and making rapid progress towards completion. The idea has been warmly taken up by the profession at large, and during the last week no less than three large and representative meetings took place in the Royal College of Surgeons for the consideration and amendment of the draft scheme which was brought before the medical societies last spring. At the general meeting on Saturday last, the rules, as revised and amended, were adopted, and the Academy may already be said to exist. Before separating, the meeting appointed a committee, consisting of the secretaries of the four medical societies—Drs. Bennett, Montgomery, Roe, and Thompson, with two provisional treasurers, Drs. Robert McDonnell and Abraham, for the purpose of forwarding to the members of the Pathological, Medical, Surgical, and Obstetrical Societies copies of the amended Rules, together with a notification of a general meeting of the Fellows of the new Academy, to be held on Saturday, the 18th, at the Royal College of Surgeons, when the election of officers for this session will take place. The names of candidates for office must be sent in to the provisional committee on or before Wednesday, the 15th. We wish to call attention to the fact that, by the Rules of the Academy, the members of the existing Medical, Surgical, Pathological, and Obstetrical Societies have the option of joining the Academy either as Fellows or as Members, the Fellows alone being eligible for office, and having the right of voting for candidates, so that any Member of these societies who pays the sum of two guineas to the provisional treasurer on or before Saturday, the 18th, will have the right of voting for the officers for the present session. We are happy to state that a very large number have already availed themselves of this privilege, and the Academy will commence with a very respectable balance at its banker's.

We need hardly say that we heartily wish the young Academy every success, and confidently predict that it will give a vast impetus to scientific work among the medical profession in Ireland. Sub-sections are to be formed in anatomy and physiology and public hygiene, and none can doubt that the amalgamated societies, which, separately, could only be said to maintain a struggling existence, will now feel the truth of the old adage "*l'union fait la force*," and, working harmoniously together, will attain results far beyond what they could previously have aspired to.

WE understand that the weight of evidence in favour of a regimental system is so great that the reinstating of a medical officer on the establishment of every cavalry regiment and battalion of infantry may be regarded as a certainty as soon as Lord Morley's Committee, now sitting at the War Office, has issued its report. Another innovation will, it is believed, be a considerable curtailment of the work outside their legitimate duties at present devolving upon medical officers, and the adoption of a better system as regards the command of the companies of the Army Hospital Corps.

LEITH HOSPITAL.—Dr. Charles W. Stewart, lately house-surgeon in this institution, has been appointed to the post of Resident Physician in the Royal Infirmary, Glasgow.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

ANDERSON'S COLLEGE, GLASGOW.—The Winter Session of Anderson's College, Glasgow, was opened on the 31st ult., Dr. Fergus presiding. Dr. Christie, Lecturer on Hygiene, delivered an interesting inaugural address. There was a good attendance of students and medical practitioners.

THE ACTION FOR DAMAGES AGAINST MEDICAL MEN AT GREENOCK.—In our columns for October 11th reference was made to a case in which the parents of a child who had died under the influence of chloroform administered for a surgical operation in the Greenock Infirmary, sought to recover £500 damages for unskilful treatment. The case was closed on Friday last by the judgment of Mr. Sheriff Smith, who said that a grave attack had been made upon the professional skill, attention, and tenderness of two medical gentlemen, which was certain to subject them to considerable anxiety; and he considered it his duty, while reserving his formal judgment until the extension of the shorthand writer's notes, to take the earliest opportunity of relieving them of that anxiety, which he would do by pronouncing judgment at once. After stating that he had every sympathy with the bereaved parents, his Lordship proceeded to say that he considered that it had been proved that the death of their girl had resulted from the visitation of Providence, and that no blame had been brought home to either Dr. Cluckie or Dr. Dobie in the slightest degree. It had been proved that chloroform had been a most valuable anæsthetic; it had been the means of saving much pain and many lives; but the administration of it in a small proportion of cases had proved to be fatal. It had also been proved that it was impossible to foresee any of the particular cases in which an unfavourable result might ensue from its administration. In this case it was evident the chloroform had been administered with the utmost care and skill and with every possible precaution, and that the parents were totally wrong in attaching any blame to Dr. Cluckie and Dr. Dobie. In his opinion it had been proved beyond a doubt that they were not to blame for the unfavourable result in the slightest degree. A question had been raised in the course of the case as to whether the parents were or were not informed that the child was to be put under the influence of chloroform. He believed that it had been proved that the mother was informed that chloroform was to be administered. But even accepting it that she did not understand that, in his opinion the surgeons were not bound to tell the parents that chloroform was to be administered in such a case as the present. It was certain, on the authority of several of the first medical gentlemen in Scotland, that the administration of chloroform had been absolutely essential in the case of such a delicate operation as Dr. Cluckie was about to perform; that it would have been improper to have conducted such an operation without the use of chloroform; that the chloroform was administered in a skilful and proper way; that on the appearance of unfavourable symptoms, not only had every means been taken to restore animation to the patient, but Drs. Cluckie and Dobie had most creditably to themselves continued to use those remedies for a much longer period than was usual in similar cases occurring in Glasgow and Edinburgh. He had, therefore, no hesitation in pronouncing decree of absolvitor in favour of both defenders.

SICK CHILDREN'S HOSPITAL, GLASGOW.—At a meeting of

the General Committee of the Sick Children's Hospital, held on the 1st inst., to elect the honorary medical staff, the following appointments were made:—Physicians—Professor Leishman, Dr. Finlayson. Extra-Physician—Dr. Gemmell. Surgeons—Dr. H. C. Cameron and Dr. William McEwan. Extra-Surgeon—Dr. Wm. J. Fleming. Pathologist—Dr. Joseph Coats. Oculist—Dr. Thomas Reid. Aurist—Dr. Thomas Barr. Dentist—Mr. Reece Price. The Committee at the same time appointed Dr. W. S. H. Walker to be resident medical officer. The directors afterwards visited the hospital, which is now on the eve of completion. We understand that there were eleven applicants for the office of physician, and nine for that of surgeon.

GLASGOW DEATH-RATE.—During the week ending with Saturday, the 28th ult., the death-rate of Glasgow was 26 per 1,000 per annum, being an increase of 4 as compared with the preceding week. The rates for the corresponding weeks in 1881, 1880, and 1879 were 24, 28, and 16 respectively.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 28th ult., the mortality in Edinburgh was 77, and the death-rate 17 per 1,000. There were 20 deaths under 1 year, and 14 above 60, of which 1 was above 80. Diseases of the chest accounted for 40 deaths, and zymotic causes for 4, of which 2 were due to diphtheria and 2 to scarlatina, the intimations of these diseases being respectively 11 and 83.

THE ROYAL MEDICAL SOCIETY OF EDINBURGH.—The hundred and fifty-fifth session of the Royal Medical Society of Edinburgh was opened on the 3rd inst., with an address by Professor Grainger Stewart. Dr. Mackenzie Johnston, president, occupied the chair. Professor Grainger Stewart called attention, in the first place, to the fact that in the social development, from the lowest to a higher type, the social organism got more and more differentiated, until at last each man was told off to some particular trade, work, and profession, and he could excel in nothing else; and that, with a yet higher development, they found that only in one department of one of these was a man able to excel. Referring to the Edinburgh Royal Infirmary and the clinical teaching which was there given, he said they would find it nowhere else so carefully and thoroughly done, and this they owed to two men—Professors Rutherford and Bennett, but more particularly to the teaching of that great teacher, Hughes Bennett. As a teacher, he had never known a man surpass Bennett. Having also insisted on the great value of the opportunities of dispensary practice, which he was afraid students were now-a-days getting to make less use of, he said that they had here in Edinburgh yet another advantage besides what they had in the University and the Infirmary—namely, the great and very important advantage which they had in the Royal Medical Society. The Society, he said, held out peculiar advantages to the student in the way of opportunities for reading and debate, and of in some way supplying the want of social intercourse which was one of the defects of the Scottish University system. In conclusion, he begged them to be ambitious, not about what place they were to gain in the world, but about the kind of men they were to be, by having high characters and thorough and well-founded knowledge, and by making the very best use they could of it. On the motion of the president, a cordial vote of thanks was awarded to Professor Grainger Stewart for his address.

CLASS ACCOMMODATION IN THE NEW UNIVERSITY BUILDINGS.—The accommodation in the lecture theatre of the Department of Surgery in the New University buildings has thus early in the session been found inadequate for the numbers attending the lectures of the new Professor. It was accordingly

announced on Friday morning by Professor Chiens that, through the kindness of Professor Turner, the class would meet for the future in the anatomy class-room, which was some time ago re-arranged so as to seat about 500 students.

THE ETHICS OF "HEALTH LECTURES."—The Glasgow correspondent of our contemporary the *Lancet* remarks in its number for the 28th ult.: "Some rather silly hostility has been manifested in certain quarters to these health lectures on the ground mainly that they afford opportunity to ambitious men to pass before the public as learned specialists, to the detriment of their professional brethren. It is, however, surely not wrong that the public should have such subjects as those named above put before them in a simple and popular way; and by whom could such instruction be more appropriately given than by medical men?" We have not the slightest notion who the "silly" objectors are, but from the standpoint of the difficulty of unravelling the science of medical ethics, we confess to a certain amount of sympathy with the condemned objections. If it be laudable to lecture the public on medical questions, some of them of extreme delicacy, and extensively advertise those lectures and lecturers, how, in the name of common sense, can it be wrong to instruct the public through the medium of books, and advertise such books, especially when, to the extent that such books are technical, they are regarded by the profession as savouring less of the advertisement? We shall be pleased to receive the opinions of some of our readers on this knotty point. It is further remarked by the correspondent of our contemporary that the last lecture of the course is, with what many regard as questionable taste, "On Healthy Motherhood," to ladies only. This is probably the complement of the very popular lecture delivered last year by another rising obstetrician, "On Healthy Womanhood." The validity of the objection is here dextrously ignored, and it is this, viz., that a lecture on such delicate points thus to be treated of, should be advertised as "to ladies only," and when the prurient imagination of the public is thus sufficiently excited that it should be distributed broadcast among the community. As to our "rising obstetricians," we understood that all our obstetricians were rising—in the night.

INSTALLATION OF PROFESSOR MACINTOSH AT ST. ANDREWS.—Dr. William MacIntosh, the presenatee to the Natural History Chair in the University of St. Andrews, was on Saturday, the 28th ult., formally installed to office. Principal Shairp presided, and was supported by several of the professors. The Principal administered the ancient oath, and invested the new Professor with the insignia of office, after which he received the right hand of fellowship from his brother-Professors.

Correspondence.

THE DIAGNOSIS OF AORTIC ANEURISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the report of the instructive case of aortic aneurism opening into the œsophagus, published in this day's (Nov. 1st, 1882) *Medical Press*, Surgeon-General Francis makes a statement which, unqualified as it is, is, I believe, opposed to clinical experience and to the teaching of recognised authorities. The real nature of the symptoms in the case in point was not, it is stated, suspected during life by the several medical attendants, thus affording another instance of the difficulty of diagnosis in many cases of aortic aneurism, although it must be admitted that certain symptoms were present in this particular one which are usually looked upon as suggestive of that disease. But it is in order that none of your readers "may take for granted," as apparently inferred by Mr. Francis, that the existence of a murmur is a constant physical sign of an aneurism of the thoracic

aorta that I am induced to address you. Mr. Francis states that "it is probable that the ear was never applied to the seat of the spinal irritation (the aneurismal tumour?), as towards the last *certainly*, if not earlier, a *bruit* must have been very audible." The occurrence, however, of murmur in thoracic aneurism is in reality so commonly wanting that Dr. Stokes looked upon it as "exceptional." Drs. Bellingham, Walshe, and Hayden have also each recorded the fact that murmur is by no means a frequent sign of the disease. Out of 61 cases of thoracic aneurism collected by the last-mentioned author, in which the point was noted, murmur was absent in 41 cases.

As regards the occurrence of flatulence in connection with dysphagia, both of which symptoms were observed for some time before death in Surgeon-General Francis's case, I may remark that Dr. Bellingham specially refers to flatulent distension of the stomach as being a very troublesome symptom in these cases of thoracic aneurism pressing upon the œsophagus. Dysphagia from this form of pressure, as is generally known, is in some instances temporary, and often appears to be due more to spasm than to diminution of the calibre of the œsophagus.

Your obedient servant,

GEORGE F. DUFFY, M.D. Dub.,
Physician to the City of Dublin Hospital, &c.

Medico-Parliamentary.

HOUSE OF COMMONS.—MONDAY.

THE MURDER OF DR. M'LEAN.

Dr. CAMERON asked whether anything definite had yet been done in the way of advancing or securing a settlement of the claim against the Chilian Government for compensation for the murder of Dr. M'Lean, the physician to the British Legation, by Chilian soldiery, at Chorillo, in January last.

Sir C. DILKE—Her Majesty's Representative at Santiago was instructed on the 28th July to include the claim of Dr. M'Lean's relatives among those already presented by him to the Chilian Government. He has also been instructed to call the attention of the Chilian Government to the injustice which the continued delay is causing to the numerous claimants, and to urge upon them the necessity for taking such steps as will ensure a settlement of these claims within a reasonable time.

THE SONS OF ARMY MEDICAL OFFICERS.

Dr. LYONS asked the Secretary of State for War if, under existing regulations, the sons of medical officers of the army were ineligible for nomination to honorary Queen's cadetships; and if he would take steps to remedy this inequality in the position of the Medical Department, which was felt as a slight to those who risk their lives in the service of the State.

Mr. CHILDERS, in reply, said—I have to remind the hon. member that the sons of medical officers are eligible for Queen's cadetships. The arrangements as to Queen's honorary cadetships are under consideration, but I can give no assurance that I can extend this system, which is a delicate one to alter.

Obituary.

GEORGE CRITCHETT, F.R.C.S.

It is with feelings of deep regret we place on record the death of one who had obtained a leading position among ophthalmologists, Mr. George Critchett. Our regret will, we know, be largely shared by all ranks of the profession, more especially, perhaps, by those who were reckoned amongst his immediate friends, and were they brought under the genial influence of his home, knew more of his kindness of heart, and his uprightness of character in every sense, for he lived in the esteem of those who had the special pleasure of his acquaintance. Mr. Critchett died on the morning of this day week, after a comparatively short illness, for his malady, cystitis, only assumed a serious aspect about a week or ten days before his death, and when those who were in attendance upon him were in a hopeful frame of mind as to his condition.

George Critchett was born at Highgate, in 1817, and having determined upon his future career, became the pupil

of Mr. Scott, then surgeon to the London Hospital. He was subsequently apprenticed to the Royal College of Surgeons, the fashion in his early days. After obtaining his diploma, he was appointed demonstrator of anatomy, and subsequently became assistant surgeon and lecturer on surgery at the London Hospital. About the same time he ardently devoted himself to ophthalmic surgery, and in due time became assistant surgeon to the Moorfields Hospital; subsequently he filled the post of surgeon and consulting surgeon to the hospital. In 1870 he was elected into the Council of the Royal College of Surgeons, his election, we believe, being almost the first instance of a specialist finding his way into that close corporate body. His reputation as an ophthalmic surgeon secured for him the vice-presidency of the several ophthalmological congresses which have been held abroad and in this country. He was also unanimously chosen a Vice-President of the Ophthalmological Section of the International Medical Congress of London, 1881, and filled, from time to time, the presidential chairs of the Hunterian and Clinical Societies, as well as of other societies. He was a corresponding Member of the Academy of Medicine, Brussels, of the Imperial Academy of Medicine, Rio de Janeiro, &c. His earnestness as an active member of the Clinical, Medico-Chirurgical, Ophthalmological, and some other societies, is too well known to need recapitulating. Among his various contributions to the literature of the profession we may particularise—"A Course of Lectures on Diseases of the Eye," which appeared in the *Lancet*, 1854; a paper on the "Extraction of Cataract in Cases of Closed and Adherent Pupil," *Lancet*, 1856; "A New Method of Forming an Artificial Pupil by Tying the Iris;" a pamphlet "On the Operation for Strabismus by the Sub-conjunctival Method;" another, "On the Linear Extract of Cataract," a very valuable paper. He was, however, not given to book making, for he was pre-eminently an *operating surgeon*, and the skill and care which he brought to bear on all occasions, and in all cases, obtained for him the high reputation which he bore to the day of his death, for he may be said to have almost died in the prime of life.

At his funeral, which took place at Highgate Cemetery on Saturday last, a large concourse of people attended to pay the last mark of respect to his memory, amongst whom many prominent members of the profession were observed. The Baroness Burdett-Coutts sent her carriage, and also sent a beautiful wreath of flowers, which was placed on the coffin along with other wreaths and crowns which had been sent by other illustrious patients, relatives, and friends in "loving remembrance."

MR. W. WALL PEARCE, M.R.C.S., OF MEASHAM, ATHERSTONE.

A VENERABLE and much-esteemed member of the profession has just passed away in the person of Mr. W. Wall Pearce, of Measham. The deceased took his diploma at the College of Surgeons fifty-eight years ago, and at once settled down to general practice in the little town of Derbyshire, where he has just died of vesical calculus. It falls to the lot of but few to pass nearly sixty years of professional life in one neighbourhood, and he who is fortunate enough to attain thereto must indeed be a popular man in the midst of his surroundings. But the breath of scandal or depreciation of professional skill appears never to have reached Mr. Pearce, who died in his eighty-second year as he had lived, respected and honoured by all classes of the community. On the day of his funeral there was almost a suspension of business pursuits. His remains were followed by thousands, and at the grave in the old parish church-yard his coffin was completely buried in wreaths of flowers. This was no mere outburst of popular excitement, but one of affectionate regard for his person, and of intense admiration of the character of the man who had lived among them an honourable and blameless life for more than half a century, and to whose memory this was a last tribute.

Mr. Pearce had been a subscriber and an occasional contributor to this journal from the very first issue, now over forty-four years, and in his death we have lost a personal friend who ever had our admiration and respect.

Faculty of Physicians and Surgeons of Glasgow.—At the October meeting of the Examiners the following candidates

passed the necessary examinations and were admitted Licentiate of this Faculty:—

J. H. Blayney, Manchester.	A. M'Ansland, Glasgow.
A. Dickson, Glasgow.	A. L. Macphail, Glasgow.
W. Dunlop, Glasgow.	John Mathie, Glasgow.
J. Emblson, Messingham.	A. D. Nalmsith, M.D., Toronto.
W. Gibb, Glasgow.	N. N. Parakh, Bombay.
G. Hunter, Glasgow.	James Wilson, Glasgow.
E. Kaufmann, Michigan, U.S.	

Royal University of Ireland.—The following candidates obtained Honours at the autumn examinations in the Faculty of Medicine:—

M.D. DEGREE EXAMINATION.—First Class Honours: Chas. H. Wise. Second Class Honours: J. M'Murray, F. E. Adams.
M.B. DEGREE EXAMINATION.—Upper Pass Division: John Riordan.
SECOND EXAMINATION IN MEDICINE (EXHIBITIONS).—First Class, £40: Benjamin Hoeford. Second Class, £20: Thomas Grainger, John Kearney, R. B. Gorsuch. First Class Honours: James Chambers, Benjamin Hoeford. Second Class Honours: Thomas Grainger, John Kearney, R. B. Gorsuch, James Norwood.
FIRST EXAMINATION IN MEDICINE (EXHIBITIONS).—Second Class, £15: T. R. Leonard. First Class Honours: J. W. Wilson, T. D. Smith. Second Class Honours:—T. R. Leonard, W. B. M'Quitty.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

CANTAB.—The possession of a medical degree conferred by a British or Colonial University is sufficient evidence of the fact, and will be so accepted by the College.

DR. CAREY.—We regret that the information is not at our disposal. The conditions under which we obtained possession of it forbid any further use being made of it at present. When we are favoured with permission to announce the matter publicly you shall be apprised of the fact.

R. S. T.—The case was an ordinary one of globus hystericus. The treatment was scarcely suited to the patient; but this fact does not explain the course subsequently pursued by your coadjutor. We should prefer to receive his account of the matter before giving a definite opinion on the subject.

A GRAND OLD MAN mistakes the nature of the *Medical Press and Circular*; his communication is entirely unfitted for publication in our columns. We do not undertake to return M's. forwarded to us, and particularly is this rule observed in those cases where stamps for this purpose are not sent by correspondents.

MR. SMYTHERS.—The custom has hitherto been invariably observed; but this year it seems to be doubtful whether any will be found to desire its continuance. On the last occasion much disagreeable confusion was created by the action of a few recently-elected members, who displayed an amount of bad taste difficult to excuse.

MR. WHITEHEAD.—The case you refer to was under the care of Dr. Thomson, at the Glasgow Ophthalmic Institution. It will be found in our issue for Oct. 11th, 1882.

EGYPTUS.—Your letter is unavoidably held over.

MR. ENSOR (Manchester).—We have known cases in which the inhalation of sulphuretted hydrogen has given rise to serious consequences. Yet certain analysts who use the gas commonly in their laboratories have stated that they have never been inconvenienced beyond the filthy smell which accompanies it.

MR. T. S. P. (Berwick).—The lines were, we believe, written by Brough, and referred particularly to King and Rowney, the opponents of Eozoon Canadense.

M.D., GLASGOW.—In our experience we have never met with a case of hair turning white instantaneously from fear, although we have often heard it asserted. We do not dispute the possibility of this in cases of sudden fright or grave mental anxiety; but its occurrence is certainly not common.

MR. WILSON (Edinburgh).—1. A new edition of Quain's Anatomy is just published. 2. You cannot do better than get the Surgery which has been recommended to you. It is not so well known as its merits deserve; this is probably owing to the fact that its author is not attached to any of the large medical schools. 3. Yes; you cannot take up a more practical guide for the laboratory.

CHEMIST.—You should apply for the information to the Secretary of the Pharmaceutical Society.

A SUBURBAN PRACTITIONER.—The card is unusual, but we see no great harm in it.

DR. JAMES.—Place no reliance on advertised "patent" remedies. The following is a prescription highly recommended for removing corns by Mr. Gerou in the (Canadian) *Medical and Surgical Reporter*:—

R Acid. salicylic, gr. xxx.;
Ext. canab. indic., gr. v;
Colloidi, f. 3ss.

This is painted on the corn with a camel's hair brush, and immediately dries, the corn coming away in four or five days. It must be repeated if necessary. No protection is necessary between the foot and the sock.

MEETINGS OF THE SOCIETIES.

HUNTERIAN SOCIETY.—This evening (Wednesday), at 7.30 o'clock, Council Meeting.—8 o'clock, Dr. Stephen Mackenzie: 1. "On a Case of Hemianopsia with Hemiplegia;" 2. "On Paroxysmal Hemoglobinuria."—Dr. Coxwell, "On Demonstration of Reflexes in a Case of Hemiplegia."

ROYAL MICROSCOPICAL SOCIETY.—This evening, at 8 o'clock, Mr. T. B. Rossiter, "On Observations on Stephanoceros."—Dr. Maddox, "On some Organisms found in the Excrement of the Goat and the Goose."

CLINICAL SOCIETY OF LONDON.—Friday, Nov. 10th, at 8.30 p.m. Mr. Gelding Bird, "On a Case of Removal of the Uterus for Fibroid Disease" (specimen shown).—Mr. Clutton, "On a Case of Spina Bida."—Mr. C. Heath, "On a Case of Separation of the Epiphyses of the Clavicle by Muscular Action." Dr. Goodhart, "On Six Cases of Diphtheria treated by the Local Application of Borax or Boracic Acid."—Mr. Golding Bird will exhibit a Case of Transpellear Excision of the Knee.

HARVEIAN SOCIETY OF LONDON.—Thursday, Nov. 16th, at 8.30 p.m. the Report of the Alcohol Committee.—Dr. Francis, "On the Treatment of Neuralgia."

Vacancies.

Ayrshire District Asylum.—Assistant Medical Superintendent. Salary to commence at the rate of £80, with board and lodging. Applications to be lodged with the Clerk to the Board, County Buildings, Ayr, by Nov. 22nd.

Bradford Fever Hospital.—Resident Medical Superintendent. Salary, £150, with board, &c. Applications to be made to Mr. C. V. Woodcock, Albany Buildings, Bradford, on or before Nov. 31st.

Cane Hill Asylum, Surrey.—Medical Superintendent. The salary and emoluments will be £700, with unfurnished house, &c. Applications to be sent to the Clerk to the Committee of Visitors not later than Nov. 30th.

Callan Union, Mullinahone Dispensary.—Medical Officer. Salary, £90, and £20 as Medical Officer of Health. Election, Nov. 10th. Wandsworth and Clapham Union.—Assistant Medical Officer and Dispenser. Salary, £120, with apartments, &c. Applications to be sent to the Clerk on or before Nov. 11th.

Appointments.

BEITH, R., M.B., Resident Assistant Medical Officer to the Western Infirmary, Glasgow.

CRESS, F. R., M.B. Lond., F.R.C.S., Surgeon to the Bristol Eye Hospital.

DUNLOP, H. M., M.B., C.M., Resident Physician to the Sick Children's Hospital, Edinburgh.

GOFF, J., M.B., Resident Assistant Surgical Officer to the Western Infirmary, Glasgow.

HARDIE, J., M.D., L.R.C.S. Ed., Honorary Surgeon to the Manchester Royal Infirmary.

MACLEHOSE, N. M., M.B., Resident Assistant Surgical Officer to the Western Infirmary, Glasgow.

MARSHALL, J. N., M.B., Resident Assistant Medical Officer to the Western Infirmary, Glasgow.

RAMSAY, A. M., M.B., Resident Assistant Medical Officer to the Western Infirmary, Glasgow.

STEWART, R. S., Resident Assistant Surgical Officer to the Western Infirmary, Glasgow.

STUART, E. O., L.R.C.P., L.R.C.S. Ed., Assistant Medical Officer to the Infirmary of the Salford Union.

WOOD, A. J., M.B., Resident Assistant Surgical Officer to the Western Infirmary, Glasgow.

Births.

ADRIEN.—Oct. 31st, at Balbriggan, the wife of Dr. E. N. Adrien, of a son.

MACKENZIE.—Nov. 1st, at 26 Finsbury Square, the wife of Stephen Mackenzie, M.D., F.R.C.P., of a daughter.

PERKINS.—Nov. 5th, at 2 Rolle Villas, Exmouth, the wife of George S. Perkins, M.B. Edin., L.R.C.P. Lond., of a son.

POIGNAND.—Nov. 2nd, at 234 Upper Street, Islington, the wife of Malcolm Poignand, M.D., of a son.

TURNER.—Nov. 1st, at 430 Camden Road, London, the wife of T. B. Turner, M.B.C.P., of a daughter.

WALLACE.—Nov. 3rd, at Oclechaston, Yorkshire, the wife of Edward J. Wallace, M.D., of a son.

Marriages.

O'CONNOR—JORDAN.—Nov. 2nd, at the Pro-Cathedral, Dublin, George A. O'Connor, L.R.C.S. & F. Edin., to Annie Mary, eldest daughter of Patrick Jordan, Esq., of Belmullet.

WEBB—HUNTING.—Nov. 2nd, at Jesmond Church, Newcastle-upon-Tyne, Henry Pelham Webb, M.B., of Lavender Hill, S.W., to Fannie, daughter of Charles Hunting, of South Hetton, Durham.

Deaths.

KITCHENER.—Oct. 19th, at King Street, Bath, suddenly, Thomas Kitchener, M.D., aged 50.

HOOD.—Nov. 8rd, at Watford, Edith, the wife of Peter Hood, M.D., of 23 Lower Seymour Street, London.

LEFEVRE.—Oct. 30, at Fortman Square, London, Anastasia, widow of H. Belfield Lefevre, M.D., late of Paris and Exeter, aged 63.

REID.—Oct. 23rd, at Newbiggin-by-the-Sea, John Campbell Reid, M.D. Glas., aged 67.

ON SOME IMPLICATIONS OF DISSOLUTION OF THE NERVOUS SYSTEM.

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P., F.R.S.,
Physician to the London Hospital, and to the National Hospital for the Epileptic and Paralysed.

I HAVE many times urged that we are much helped in our scientific studies of diseases of the nervous system by considering them as examples of Dissolution, using this term as Spencer does, for the reverse of Evolution. To those who accept the doctrine of Evolution it will readily be granted that this way of regarding nervous, and, indeed, all other diseases, is now-a-days imperative.

I have, in a recent paper in this journal (1881), spoken briefly of the hierarchy of the nervous centres according to the doctrine of Evolution. Three orders of centres were indicated—highest, lower, and lowest. I should now say highest, middle, and lowest centres—a mere change in the name of one of them. This order need not be re-stated. (a) I wish here to consider together very briefly several things which Dissolution implies. I have in other papers illustrated them by cases of disease, but I think it will be convenient to state them in chief measure diagrammatically

(a) I may mention the hypotheses that Progressive Muscular Atrophy is owing to wasting of cells of lowest motor centres; that Paralysis Agitans is owing to wasting of cells in the middle motor centres; and that the General Paralysis of Allenists is owing to wasting of cells of the highest motor centres. In each case it is supposed that the cells waste in the order from smallest towards largest.

by aid of entirely artificial illustrations. (b) The reader is asked to bear in mind that illustration, not proof, is attempted in this paper. He is asked, indeed, not to accept any part of what may be inferred until he has convinced himself that the *principles* illustrated apply to actual cases of disease.

The subjoined series of statements may seem to be about very different things, but each is really only on a different aspect of one thing—Dissolution.

It must be understood that this is a purely materialistic study. All centres are supposed to be sensori-motor—the highest as certainly as any lower. In a word, the nervous system is to be thought of as a sensori-motor machine. That states of consciousness attend activities of parts of this mechanism is perfectly true, but that does not concern us in this limited exposition, except now and then indirectly. As our purpose is simply to illustrate, we speak of centres as if they were motor only, and we ignore the cerebellar system.

(1). Nervous centres represent movements, not muscles. From negative lesions of motor centres there is not paralysis of muscles, but loss of movements. Convulsion from excessive discharge of motor centres is to be looked on as the strong development of many movements at once, or, rather, as a contention of many movements.

(2). There is no Localisation in the sense that every part of a centre represents an external muscular region in the same way as all other parts of the centre do. There is,

(b) The terms "centre" and "muscular region" are used very arbitrarily in the following exposition.

to illustrate, no cerebral centre every part of which represents the arm and the leg equally.

(3). There is no Localisation in the sense that each part of a centre, or any centre, represents exclusively any limited region. To illustrate, there is no cerebral centre for the arm only, nor is there one for the leg only.

(4). Each part of a centre represents the whole of a muscular region, and each part of it represents the whole region differently. Thus, in an hypothetical centre representing the face, arm, and leg, each of, say, three parts of it, represents the face, arm, and leg, but in one part the face is most represented, in another the arm, and in another the leg.

(5). The higher the centre the more numerous, different, and more complex, and more special movements it represents, and the wider the region it represents—Evolution. The highest centres represent innumerable, most complex, and most special movements of the whole organism, and in accord with No. 4 each unit of them represents the whole organism differently. In consequence, the higher the centre the more numerous, different, complex, and special movements of a wider region are lost from a negative lesion of equal volume—Dissolution.

(6). It is an obvious corollary from the preceding that the higher the centre, whilst the wider spread the paralysis the less in degree is it in any one part from a negative lesion of equal volume.

(7). There is Compensation, never absolute, in cases of partial destructive lesions of centres.

(8). From increasing extent of negative lesions paralysis increases in compound degree. There is more paralysis of the parts first affected, and there is greater range of paralysis.

(9). From increasing discharges of centres the spasm spreads in compound order. There is more spasm of the parts first involved, and greater range of spasm.

(10). We have, however, to consider not only the extent of the destruction, but the rapidity of the destruction—the “gravity” of negative lesions. The more rapid the destruction of part of a centre, the wider spread is the paralysis, some of which is temporary.

(11). We have in the case of “discharging lesions” to consider not only the quantity of energy liberated, but the rate of its liberation. The more rapid the discharge of part of a centre the wider is the range of spasm attained, and the sooner over is the convulsion. (a)

(12). The higher the centre the more “intense” are the paroxysms on excessive discharges beginning in part of it (the more quickly does the spasm spread and the sooner the convulsion is over).

(13). After sudden excessive discharges there is tem-

porary exhaustion of the nerve fibres concerned during the paroxysm and consequent temporary paralysis.

(14). When there is discharge of part of a higher centre giving rise to currents not strong enough to overcome the resistance of the next lower centre, the currents spread more widely in (“are boxed up in”) the higher centre.

(15). The higher nervous arrangements inhibit (or control) their lower, and thus, when the higher are suddenly rendered functionless, the lower rise in activity.

We now illustrate the foregoing dicta by an artificial scheme. We speak of but one centre for a time; some of the dicta will require consideration of a hierarchy of centres. We speak of a centre, and of a region represented by it. The region has, we shall suppose, only three muscles, each of which is different in size, shape, and has different attachments from the others. We suppose the centre to represent seven different movements, in every one of which all the three muscles serve, but that in each of the seven movements the three muscles serve differently. We symbolise this in the subjoined expression of seven terms from $x^{21} y^3 z$ to $x^7 y z$. (b)

Each muscle is a bundle of muscoli, each musculus is made up of a great number of muscular fibres. Thus, when we speak of representation of muscles, as a movement, it is understood that some elements of muscles may be alone represented. We shall in the illustration, for the most part, use the term muscle. We shall symbolise the muscles represented by the capital letters X, Y and Z; we continue to symbolise the nervous arrangements, representing movements of them by x , y and z . There are terms in the centre in which the muscle X is much represented, and Y and Z slightly; there are terms in which Y is represented much, and X and Z slightly; similarly for Z. But each term represents some elements of every one of the three muscles. No two terms represent X, Y and Z in the same way. There are seven different movements in each one of which X Y and Z serve differently. In the expression as a whole, X is supposed to be most, Y less, and Z least represented.

Thus, our hypothetical centre does not represent three muscles, but seven movements, or we may say it represents muscles which have yielded their individuality into seven different movements. (c)

Hence it follows that we have not paralysis of muscles, but loss of movements from destruction of terms. Destruction of any one term produces loss of some one movement of the whole external region, does not paralyse a single muscle. Destruction of no term produces loss of the same movement as destruction of any other does. What appears to be perfect paralysis of the region is destruction of all or of most of the terms. Discharge of any one term would develop a particular movement. Discharge of no term produces just the same movement as of any other. Excessive discharge of all or of many of

(a) Once for all let me say that I neither deny nor affirm that nervous discharges and nerve currents are either more rapid or less rapid in any case of disease than in health, as some expressions used in these pages, if literally taken, may seem to imply. A rapid discharge is supposed to be a great number of cells discharging at once—a great quantity of motion in a short time; similarly for nerve currents.

(b) (1) $x^{21} y^3 z$ + (2) $x^{14} y^3 z^2$ + (3) $y^{15} z^2 x^4$ + (4)

(c) To avoid circumlocution we speak of destruction or discharge of a term when strictly we should speak of destruction or discharge of the nervous arrangement symbolised by the term.
 $y^{14} x^6 z^1 + (5) z^{15} y^3 x^2 + (6) x^{14} y^3 z^2 + (7) y^{15} z^2 x^4$

the terms simultaneously produces severe convulsion, for convulsion is nothing other than the sum of the contentions of different movements; to call it spasm of muscles is misleading.

We must bear well in mind that on destruction of one or more terms, the other terms remain; this seems to be a barren truism. (a) But the "muscles" are said to be "weak" when part of a motor centre, representing a muscular region, is destroyed. It is scarcely vividly recognised that this means absolute loss of some movements of the whole of a region, and persistence of other movements of the whole of that region. The condition of things in what is called partial, or better, imperfect, paralysis is duplex, negative, and positive.

Now for the increase of paralysis from increasing extent of negative lesions. The index represents the degree with which each muscle is represented in each movement. Thus, in the first term ($x^1 y^3 z^1$), X is represented twenty-one times more (by twenty-one times more fibres and cells) than Z is, but X is nevertheless represented more or less in every other term; in the last, the seventh, very slightly, where Z has most representation ($x^1 y^1 z^7$).

The progress of paralysis from increasing up to total destruction of the centre thus symbolised is not $x^{23} + y^{23} + z^{23}$; it is not that the muscle X is perfectly paralysed, after that the muscle Y perfectly and finally, Z perfectly. Indeed, there is no such paralysis from increasing central lesions. There is gradual loss of movement after movement each of which is a different movement of the whole muscular region represented. There "appears" a gradual loss of power over the muscles and in a certain sense there is. Let me explain further.

When the first term ($x^1 y^3 z$) is destroyed, there appears to be decided paralysis of the muscle X, but really there is only loss of a movement in which that muscle serves more largely than it does in any other of the seven movements—of one in which, however, Y serves but yet slightly, and Z also but very slightly, so that the muscles Y and Z do not appear to be appreciably paralysed. When the next term is also destroyed, there appears to be still more paralysis of the muscle X, for now thirty-five X's are lost and there now appears to be some decided, and yet slight paralysis, of the muscle Y, for five Y's are lost; there appears as yet only a trace of paralysis of Z. In reality there is loss of two movements in each of which the muscles X Y and Z serve, but in greatly different proportions. The loss is now $x^{35} y^5 z^2$.

Thus we see illustrated that from increasing extent of negative lesions of centres paralysis increases in compound order—more paralysis and greater range of paralysis, or paralysis becoming decided over a greater range. (b)

(a) It would cease to appear a truism were we considering actual cases of disease. For then we should see that the order of loss of movements upon destruction of centres is in the order from the loss of the most voluntary towards the most automatic, or more correctly speaking, from the least towards the most automatic.

(b) Thus from a lesion of the corpus striatum we have paralysis of

At length comes a time, say four terms are destroyed, when X appears to be almost perfectly paralysed, forty-eight x's being lost; there are then not enough x's (only six) in the terms which are left to move that muscle only one-fourth of the normal; by that time Y appears to be very much paralysed, only one-half the Y's remaining. It is scarcely necessary to carry the symbolisation further for our present purpose.

Of course the destruction might begin in any part of the centre, say at the other end of the expression; then the muscle Z would appear to be most paralysed at first; the paralysis spreads in a compound order of another variety. There are cases of hemiplegia in which the arm suffers more than the leg, and cases in which the leg suffers more than the arm; in most cases of the latter the upper part of the arms suffer more than the lower part; in this variety of hemiplegia, when on the right side, there is very little attendant affection of speech or articulation. (a)

No doubt, as already implied, a part becomes "paralysed to the will," as the popular expression is, when all the terms representing that part are not destroyed. Let us here, leaving for a moment our artificial illustration, suppose there to be lesion of a plexus just below the middle centres, a case of hemiplegia from lesion of the internal capsule. And let us suppose that the arm, to which region we limit the illustration, is absolutely immobile; it does not follow that the whole of the internal capsule is destroyed. "Paralysis of the arm to the will" in such a case is only a crude popular way of expressing that the muscular region is cut off from the influence of the highest centres; the highest centres are intact, but (through the middle centres) cannot "get at" the region, or else not in sufficient degree to move it, because there is a gap on the way. We must remember, in the first place, that it requires liberation of a sufficient quantity of energy in a certain time to move anything. In the kind of case we are dealing with there is no reason to suppose that a normal liberation of energy by the highest centres does not occur. If we say the patient can try to move the paralysed limb we admit this, for there is no abstract faculty of trying. When he "tries" there is liberation of energy by his highest centres. That liberation is ineffective because in the plexus injured, although some fibres may remain, they are not numerous

the face, arm, and leg, that is, loss of so many movements of those parts; from a more extensive lesion of this organ there is more paralysis of those parts, loss of still more movements of the face, arm, and leg, and in addition loss of movements for turning the head and eyes to the side on which the limbs are paralysed.

(a) It may be well to give a simpler illustration, and even more roughly. In Duchenne's Glosso-labio-palatal paralysis there is ultimately paralysis of the tongue, lips, and palate, as well as of other parts which in this illustration we shall ignore. The progress is not that the tongue is completely paralysed and so on, is it not to symbolise, $T^3 + L^3 + P^3$ it is $T + T^2 L + T^3 L^2 P$ &c. The tongue is slightly paralysed, then it is more paralysed, and at the same time the lips slightly, &c.

enough to "carry currents" sufficiently forcible to move the external part. We see, however, that in some such cases parts perfectly "paralysed to the will" become subject to severe convulsion. This means that although normal, healthy discharges of the highest or middle centres cannot move them, excessive discharges of the highest or middle centres can, and do. In the convulsion the discharges are hypernormal, excessive, and a sufficient quantity of energy is liberated suddenly and rapidly enough to compel development of many movements of the limb in spite of the fact that but few paths for the currents remain.

The just-instanced facts are important with reference to several aspects of Dissolution. It is important to note that a region may be perfectly paralysed *throughout* and yet be occasionally convulsed *throughout*. This double fact is in entire harmony with the method of representation, and with the hypothesis of localisation propounded in this article. For, as we said before, on destruction of some terms of the centre some movements of the *whole* of the region are lost, but at the same time some movements of the *whole* of the region remain. So we see the explanation of the superficial paradox that an arm absolutely immovable *throughout* by "efforts of volition," that is by normal discharges beginning in the highest centres, is nevertheless convulsed *throughout* by excessive discharges of those or of the middle centres. Convulsion, we repeat, is a development of many movements at once; in the case we are now dealing with the development is of course of the movements that remain, but each of them is a movement, although a different one, of the whole arm. Such cases are in complete harmony with the principle of Compensation.

Method of Representation and Localisation are only different names for one thing. The foregoing statements imply that I am not what has been called a Universaliser. (a) I have never believed that in any centre, in either the narrowest or widest sense of that expression, external parts are represented uniformly through it. The universaliser's representation would be symbolised by terms representing X Y and Z , such as $x^{21} y^{11} z^0 + x^{21} y^{11} z^0 + x^{21} y^{11} z^0$, &c.—that, in some centres at least, external parts are represented, say the movements of the face, arm, and leg, uniformly. Such can scarcely be called localisation at all. If every unit of a centre represents the external muscular region in the same way, where is there any basis for the representation of the *different* movements of the muscular region as a whole which plainly occur? It is plain enough that a man can make many different movements in each of which the whole of the muscles of the arm are differently concerned. If a centre of the constitution the universalist supposes were to discharge excessively part after part, there would be no sequence of convulsion, as there really is from excessive discharges of centres; there would only be gradual intensification of the same spasm. It may be said, however, that the discharge spreads from one centre representing a region alike in every part to another centre representing another region in the same way. This is a hardy hypothesis for the explanation of convulsions seemingly beginning in the forefinger and by gradual and highly compound sequence becoming universal.

Nor am I a Localiser. The Localiser's symbolisation would be $x^{24} + y^{24} + z^{20}$. On his view there is a centre for, let us instance, the movements of the face only, one for those of the arm only, and one for those of the leg only. This seems to me to ignore that there is in healthy operations co-operation of movements of different regions. If such centres were to discharge we should have complete convulsion of one limb and then of another completely, whereas we have an intricate compound sequence of convulsion. Thus, in comparatively slight epileptiform convulsion we have—to describe it very roughly—spasm of the forearm, then more spasm of that and spasm of the face also, then more spasm of these two

and spasm of the leg also. This sequence may, however, on the localiser's view, be accounted for by centre after centre becoming gradually engaged, a second centre being engaged before the discharge of the first is over. In any case, the question is not to be narrowed to the evidence supplied by convulsive seizures. Any view of localisation has to be tested not only by the phenomena of these, but also by the order of spreading of paralysis from local destructive lesions, and by the facts of recovery from paralysis when the destructive lesion is not repaired, (compensation), and by other facts stated and to be stated.

The reader must remember that I am giving but a sketch of a very complex subject. Let us return to a case of hemiplegia in which there is in addition to the paralysis of the face, arm, and leg, loss of movements for turning both eyes and the head to one side. In most cases the patient comes in a few hours or days to be able to move his head and eyes seemingly as well as ever. I believe that the patient, although he so far recovers, has lost for ever some movements for turning his eyes and head to one side, but that there are enough of those movements left for these turnings. It is from the *sudden* loss of some of the movements indicated that he had the deviations. I believe indeed that in a case of hemiplegia when there are no such deviations there is nevertheless a loss of some of the movements mentioned, but of so few that there is no obvious inability. Nay, indeed, I think there to be in a case of hemiplegia loss of some movements of the whole of the body, and that the parts "not paralysed" are movable by other remaining, intact, nervous arrangements. There are two reasons why a region escapes paralysis from partial lesions of a centre. Besides the obvious one that the region is not represented at all in the centre there is the other reason that it is very much represented in it—in every part of it. Suppose a centre to represent one hundred different movements of a muscular region, and that one-twentieth of the centre is annihilated, ninety-five movements of the muscular region remain, and thus the paralysis would be, practically, none.

My symbolisation is that each of the seven terms represents X Y and Z ; so far I agree with the universaliser; but then I go on to add that each term represents different combinations of X Y and Z ; so far I agree with the localiser. Thus I repeat I am neither a universaliser nor a localiser. (a) In speaking of the corpus striatum as a mass of little corpora striata, each of which represents the arm (limiting the illustration to that limb) as a whole, each a movement of the whole arm, I have added that each represents a *different* movement of the whole arm. It may perhaps be said that if the representation were of movements of the whole arm we could not make a movement limited to the forefinger. This is taking the statements which are only made for rough illustration literally. We could illustrate nothing did we not make artificial separations. We must, for any degree of clearness of exposition, begin by arbitrarily assuming a region to be separate. Besides, in moving the forefinger the whole arm must be kept in some attitude. Further, a nervous arrangement for the whole arm may discharge so slightly as to produce slight movement of a part of a muscular region the whole of which it represents without being able to appreciably stir other parts of that region.

(To be continued.)

(a) In consequence I have been attacked as a Universaliser and also as a Localiser. But I do not remember that the view I really hold as to localisation has ever been referred to. If it is, it will very likely be supposed to be a fusion of, or compromise betwixt, recent doctrines. I stated it plainly many years ago, so that it is independent of any recent doctrines on localisation. Indeed, as I say in an article (*Medical Times and Gazette* December 21, 1867) on *Disorderly Movements of Chorea and Convulsion, and on Localisation*, I derived it from Herbert Spencer. If any one should by chance take the trouble to refer to that article he is asked to remember that it was written fifteen years ago, and to note that the word "movement" is there used less precisely than I now use it, and further that I did not then so carefully distinguish betwixt the psychical and the physical as I now try to do.

(a) I here refer, to avoid side issues, to the cerebral centres only.

ON SOME RESULTS OF ANTISEPTIC SURGERY. (a)

By WILLIAM THOMSON, M.A., F.R.C.S.I.,
Surgeon to the Richmond Hospital, Dublin.

CLEANLINESS in surgery is a phrase which has been much heard of during late years; and it is one which has a meaning somewhat different from that which belongs to it among the laity. We do not mean by it only palpable concrete dirt, dusty floors, and filthy dressings; but we mean by it also the dirt which is impalpable, the dirt which clings about wards in the shape of viewless contagion, and which is not less dirt, and danger, too, because we do not see it with our eyes. But we can see its effects if we place an open wound near a patient suffering from erysipelas, for that wound will most likely be attacked by the contagion; or we may see it in an outbreak of the same disease in a ward in which a person so affected has been lying. This tendency to the contamination of large hospitals where surgical cases have been under treatment, impregnating the walls and floor and furniture with the exhalations from foetid wounds, was made the subject of some very able observations by the late Sir James Simpson. And although his conclusions have not been universally accepted, there can be no doubt at all events that the principles upon which he set out are not to be controverted. Wards do become surgically filthy, although very often they are apparently clean; and, as in some magnificent mansion we occasionally see an outbreak of typhoid fever due to an untrapped and unventilated drain, so we may have in apparently safe hospitals the seeds of the most pestilent of surgical plagues.

A comparison of the death-rate in large hospitals and in small, in other words, in metropolitan and in country hospitals, showed that the country had much the best of it as to results. Thus, of 2,089 amputations in hospital practice, 855 died; and of 2,098 in country practice, 226 died; giving an excess to hospital practice of 629 deaths. To put it in another form, in metropolitan hospitals containing from 300 to 500 beds, 1 in 2·4 died; in provincial hospitals containing from 201 to 300 beds, 1 in 3·5 died; in provincial hospitals containing 25 beds, 1 in 7·1 died; and in British private practice 1 in 9·2 died.

But even the worst of the London statistics showed favourably when compared with those of Parisian hospitals. Malgaigne and Trélat collected figures which showed that of 1,656 cases of amputation, nearly 1 in 2 died. In 1861 in Paris 64 out of 81 died, or 1 in 1·2, while the London results showed 1 in 2½.

It will be seen, therefore, that the skill and experience of surgeons distinguished among the best of their profession were of no avail to bring down the death-rate to a level with that of the country; and it was charged that there was in the air of hospitals where large numbers of patients are brought together, a pernicious something which slew its victims in hundreds. But so far as that was true as accounting for the appalling discrepancy, it was not the whole truth. It only proved that town air is less healthy than country air; that it is less contaminated with smoke and organic particles in a state of decomposition, a condition which one can hardly hope to see removed so long as we have crowded manufacturing centres.

But as I have said, it was only partly true, for there also came in to disturb the equality of statistics the very elements to which I have asked your attention—the physically degrading influences which, paradoxical as it may seem, attend our highest developments of civilization. The crowded courts of London were the sources from which came forth the subjects for operative surgery. They had none of the robustness and vigorous life of their country fellows, and what little stamina they inherited from tainted parents, was often still further reduced by wilful vicious living, and the ceaseless struggle for bread.

But even with all these safeguards of which I have spoken, in the best class of metropolitan hospitals the rate of mortality has not been so much reduced as you might expect—except under new conditions of which I shall have more to say. Other influences than those which could be negated by any degree of care in the selection and preparation of cases were evidently in operation, and had to be dealt with.

In the 15 years from 1860 to 1874 Guy's Hospital shows 35·4 per cent. in 361 amputations; St. George's 31·6 in 342; and in a group of 11,427 amputations collected from French, American, German, and English hospitals the death-rate is 35 per cent. Thus it is clear that the average death-rate was something like 1 in 3—and this under the best available conditions of treating wounds under the old method—high-class surgery, properly-directed nursing, and the best system of ventilation.

It was such disappointments as these, when it seemed that everything possible had been done, that urged to still further investigation and experiment, and if we turn to the more recent developments of what is understood as antiseptic surgery, as taught by Lister, we shall find a very great change indeed. It is to the distinguished labours of that great man and benefactor of humanity that we owe what safety we now enjoy in operative surgery. He showed that in wound-fluids undergoing putrefaction there are present certain organisms or germs, indefinite in structure but definite in outline, to be easily recognised by aid of the microscope. He proved, as I think indisputably, that if we could exclude these germs or destroy their vitality, when we make an incision into soft parts, and afterwards prevent their access by means of a dressing so prepared that all air passing through it must have its contained organisms killed, we should keep the wound aseptic, or unpoisoned, and thus reduce it to the state of a subcutaneous one. The best illustration of such a wound is presented in a case of fracture in which no lesion of the skin has taken place. Here there is a laceration of the soft tissues, but there is usually no suppuration, and the injury so inflicted proceeds to cure at all events without suppuration.

I am not about to enter into a description of that method, or to discuss its principles. They are well known to all the surgeons and physicians here. They are being constantly illustrated in this theatre, and in our wards; and Mr. Stokes, in addresses from this place, and more recently in his brilliant oration at Worcester, has upheld the banner of antiseptic surgery in a manner which made all who heard him proud of our School of Irish Surgery and proud of this hospital.

But as I have troubled you with figures to indicate the results which followed the best of what may be called septic surgery, or the old method, I must ask your attention to a few more, as showing what the new system is capable of. We have seen what the most careful treatment of wounds on the ordinary plan could do, backed up by all the knowledge Medicine has given us as to the selection and preparation of patients, and the general improvement of their surroundings. We have seen that in spite of all these the death-rate has remained at a height which, as Sir James Simpson observed, gave a man on the operating-table a less chance of life than if he had been on the field of Waterloo.

I will take some German hospitals first; and I do so because in these the mortality was at one time of an

(a) Abstract of Introductory Lecture, delivered November 2 1882.

appalling character. None of the ordinary principles of sanitation were thoroughly carried out; and as a consequence they were far behind the hospitals of this country, in which great attention has long been paid to these matters. But awakened by the noise of Lister's successes, the Germans tried his treatment, and it seemed to act like a magician's wand. In 1871, Volkmann, of Halle, for instance, found his deaths from blood-poisoning so numerous that he was about to close the Klinik altogether, when he determined to introduce Listerism. At that time he had lost 12 out of 16 compound fractures; since then he has published three years' experience in the treatment of these injuries, with the satisfactory result that of 75 cases not one died.

Schede, of Berlin, has collected 321 cases of amputation in German hospitals done antiseptically, with 14 deaths, or 4.36 per cent. Now of these 8 died on the day of operation from shock or hæmorrhage; and deducting these figures, as we do properly, because they do not affect this question of wound treatment, there was a death-rate of 1.9 per cent. only.

In 387 cases done under the old method, the death-rate was 28.42 per cent. In his own practice 96 amputations for injury showed a mortality of 5.2 per cent.; 138 for disease, 1.4 per cent.; or an average of 2.9 per cent.

Again, take the astounding results obtained by Bardenheuer, of Cologne, a city in which the sanitarian has ample scope for his labour. In 123 cases he had not a single death, and these operations comprised 41 amputations, with 17 of the thigh, 10 disarticulations—one of them at the hip-joint—53 resections, including 15 of the hip and 12 of the knee.

Or to take one of the English country hospitals—that of Cumberland—where the deaths used to be 25 per cent., and of these the deaths by pyæmia 42 per cent. In 1877 and 1878, in 49 amputations there were only 4 deaths—3 within 24 hours, and one from tetanus; but not one from any infective disease.

I could multiply proofs of the enormous diminution of death caused by the use of the antiseptic method of Lister, but it is unnecessary to go further than to say in corroboration of these figures that in this hospital we had in over 600 operations of all kinds in the past three years, a mortality of only 3.6 per cent. In these were included ovariectomies, disarticulations at the hip-joint, many resections of joints, and, indeed, most of the surgical procedures. In abdominal sections we have been signally successful, having lost only 1 out of 10 cases, which included 2 removals of the uterus and 8 ovarian tumours.

It has been said by some opponents of the Listerian method that these precautions are all very useful in an unclean atmosphere, but unnecessary in a pure one. Well, that is true; but who will provide us with a pure atmosphere? Theoretically it may exist, but practically in no hospital does it exist. In the air of every ward where there are suppurating wounds there are myriads of germs ready to take up their abode in the fluids of newly-made injuries, and to set up there the putrefactive action which leads to blood-poisoning. By what process, then, can this sequence of events be prevented, unless it be by one which will make these germs impotent as they fall, and prevent any from afterwards reaching the divided surfaces.

One would think at first sight that a system which had proved itself of such practical good, and had robbed operations of much of their terror, would be universally accepted. But as is always the case, any great change meets with opposition, and it has been so with the revolution worked by the Listerian method. There is always a residuum which clings to old ways because they are old, and who can give you hardly any better reason than that. They hate all innovation, fearing that they may be shaken in their old grooves, and they regard any one who speaks of change in our art as a sort of surgical Socialist. When they have nothing better to urge they use hard words. And we are not surprised to find that the author of this system has been badly pelted with sharp phrases by those

who would not accept his principles. He has been told that he has discovered nothing, that he has been a trader on other men's capital, and a user of other men's brains. But I am glad to say that the opposition which I have referred to is not more formidable in numbers than it is in reasoning, and that we may freely let it fondle the delusion that it will uproot what has been planted in such good surgical ground.

In Medicine we are familiar with a class of diseases that are called preventible, such as the different forms of infectious and contagious disorders. We know that where overcrowding, uncleanness, and poverty are co-existent there will be found the best breeding-place for typhus. And this knowledge directing our thoughts to the question of high rates of mortality, has shown that even in surgical wards there are preventible diseases. The conditions are the same, and in a certain sense also the results are alike. In operation cases under the old treatment the surgeon was always haunted with the dread of poisoning in the shape of pyæmia, or septicæmia, and we unhappily know what fatal troubles they are. Now if the Listerian principle be true in theory and in fact, and if the method devised be successfully carried out, this terrible enemy of the surgeon ought to be banished. Without Listerian precautions we know that at least one-half of the deaths are caused by some form of sepsis acting upon the blood. With these precautions, as we have seen, infectious diseases may be said to have been removed from the list of surgical affections.

These facts, however, have given occasion to Mr. Holmes, of London, to make a statement which cannot be passed over, particularly as Mr. Savory, of St. Bartholomew's Hospital, had previously implied that while the treatment was very useful for those dirty institutions, it was unnecessary in such an hospital as, for instance, his own. Mr. Holmes says: "Very exaggerated estimates have been formed of the difference which the introduction of antiseptic surgery is believed to have made in the treatment of ordinary cases. These estimates are mainly based on statistics published by foreign surgeons from hospitals where little attention seems to have been paid to hospital management, and where consequently pyæmia and erysipelas were allowed to prevail unchecked."

It is quite true that hospitals may become so impregnated with poison as to be dangerous to patients; but if in such places as these German sick-houses, pestiferous as they are said to have been, such marvellous success has been attained, what greater proof of the value of Listerism could be asked for? Mr. Savory makes the liberal admission that he regards a carbolic spray as better than a pestilential atmosphere. But who shall determine when the atmosphere is not pestilential, as regards an open wound. He admits that there are germs in the air so small as to be beyond the powers of the microscope. By what means is it made clear that the atmosphere coming in from London or other streets is pure, though all the sides of a ward be windows or the walls be burrowed with chimneys. Is it quite certain that this special ventilation will sweep away all the exhalations from other patients, and that the eddies caused by opposing currents of air will not carry troops of vigorous poison-germs upon the wound at the very time we deem the ward to be purest? May not the very "pestilential atmosphere" of which Mr. Savory speaks, however small in extent, be actually present at the wound surface, with great potency for mischief? If, then, it be impossible to determine this point, if we cannot know at what moment a tear may occur in the granulation tissue and expose the patient to risk, is it not reasonable, even on Mr. Savory's own showing, to adopt a method which gives us such security?

I have referred to Mr. Holmes' criticism upon German hospitals; and when we hear this cleaner-than-thou principle propounded, it is not unnatural that we should see how far a so-called pure English hospital differs from a dirty German one. I turn at once to the records of St. Bartholomew's, to which Mr. Savory belongs. And what do

we find there? Why, that in the eight years from 1874 to 1881 there were 236 cases of erysipelas, with 32 deaths, and 64 cases of pyæmia and septicæmia, of which 58 died, and only 6 were saved. Observe that these were not imported cases, for I have carefully excluded them. They all arose in the house, most of them after operation. Such are the results which have been attained by so-called modified antiseptics—which mean in practice none at all—in the largest and one of the best-equipped London hospitals, where, unfortunately, the treatment of wounds is not universally carried out according to Lister's teaching, but where washing with tepid water and Condy's fluid, and the application of a bread-and-water poultice to relieve tension, make up the greater part of this method. As a comparison with these figures, I may say that in this hospital a case of pyæmia is almost unknown under antiseptic precautions, and that in the past three years only one has occurred, in spite of our noxious surroundings.

A system which has changed the whole face of modern surgery—which has prompted and made possible the most daring enterprise—which has not only saved thousands of lives, but has enabled us to remove painful diseases by the knife, which otherwise must have been abandoned—this is not a system to be destroyed by the passive or active obstruction of those who are dawdlers on the road of progress. We do not say it is perfect; we do not bind ourselves to any special antiseptic agent; we do not think that finality has been reached by Listerism, as some assert we do; but we do say that, so far, it gives the best results—that so far it is an unhopèd-for good conferred upon suffering humanity.

Clinical Records.

A CASE OF MOVABLE KIDNEY.

By HENRY DAVY, M.B., M.Ch., Univ. Dub.

Medical Officer of Crumlin, and Tereure Dispensaries, co. Dublin.

On the 11th of September, 1882, I was consulted by a Mrs. P., a thin, delicate, anæmic woman, æt. 57, for "rheumatic pains." She is a widow, the mother of three delicate children, two of whom died in infancy. She is by occupation a ladies' companion, and has always lead an easy, somewhat sedentary life, her habits have been always temperate. She takes, however, wine or porter at her dinner. All Mrs. P.'s confinements have been natural and easy, and she never had a miscarriage, her monthly health has always been normal as to time and quantity. She never suffered from dysmenorrhœa. Menstruation has ceased for the last six years. About 26 years ago Mrs. P. remembers to have received a severe blow in the lower part of the right side of her chest from her husband, from which she suffered for about a week, but this did not prevent her following her usual domestic duties, nor was she under any medical treatment for it at that time. For the last ten years she has been troubled with rheumatic pains, which she attributes to sea bathing in cold weather, and remaining too long in the water. The pains first made their appearance in her hands and arms, but have now extended round her back and to the abdomen, the slightest change in the weather aggravates the pains, especially cold, wet, foggy seasons. She is naturally inclined to be chilly, and is obliged to wear a quantity of flannel to keep herself warm; she was never in the habit of lacing tightly; the slightest exertion puts her into a perspiration; she sleeps well at night, except when disturbed by the pains; her bowels are naturally constive, not moving for three or four days, unless she takes opening medicine. The tongue is covered with a whitish fur, and her breath smells strongly acid. Pulse 80, heart and respiratory sounds are normal.

Mrs. P. having complained of pain and soreness of her stomach at the time she consulted me; I was induced to make an examination of the abdomen in the recumbent position, and on passing my hand over it: I felt in the right hypochondriac region, a little below the ribs, a hard, smooth, oval tumour, dull on percussion, of the size, shape, and feel of the kidney, which can be pressed easily in the following directions, viz., downwards, where its lower margin can be felt two inches below the umbilicus; upwards, under the ribs, where it can

be made to almost disappear: into the epigastric region in the mesial line, and back into its own place in the right lumbar region. The left kidney appeared to be normally situated. The displaced kidney can be pressed with a very considerable degree of force, and handled rather roughly without giving rise to any pain, nausea, sickness, or any other uneasy sensation. On turning the patient on her hands and face for the purpose of examining the lumbar region, I observed that the ribs at the lower border of the thorax were visibly bent in, or flattened on the side of the displaced kidney, at the site where she received the blow from her husband. On percussing the lumbar region the percussion note is somewhat clearer on the right than the left side. Owing to the emaciated condition of the patient, the abdominal aorta can be seen, and felt to pulsate in the epigastric region. I observed also in the same region a hard immovable mass, about the size of the hand, extending from the ensiform cartilage, to near the umbilicus; (most probably due to malignant disease), and above this mass four or five loose bodies of irregular shape, varying in size from a half-penny to a crown piece, could be felt through the abdominal parietes which were easily moved about by pressure. The glands in both groins are enlarged, indurated, and painful when pressed, but there is no enlargement of the cervical or axillary glands.

Mrs. P. complained much of dragging, darting, shooting pains in the abdomen, and a feeling of constriction, or tightness as if a tight band was tied around her waist. She is not able to stand long, as it brings on a painful dragging sensation from her loins. She never remembers to have had an attack of renal colic. I found on examination her urine was of a pale straw colour, and strongly acid reaction, sp. gr. 1015, and free from albumen. She passed 20 to 24 ozs. in the day. The kidneys do not give her any inconvenience, and there is no difficulty on micturition. She is, however, sometimes troubled with flatulence, nausea, and vomiting.

About ten years ago when Mrs. P. first suffered from rheumatism she consulted Dr. Symes, of Kingstown, and on his examining the abdomen he also discovered she had a "loose or floating kidney," this was the first intimation Mrs. P. had that there was anything wrong with her kidney, which has remained the same size ever since, and she did not observe that it became enlarged, or painful at the menstrual periods.

The following treatment was adopted in this case:—

Having first reduced the kidney to its normal position in the lumbar region, I placed a broad flannel bandage round the waist; which I directed to be constantly worn, and underneath this a belladonna plaster. For the rheumatic pains I prescribed mixtures containing bicarbonate and iodide of potassium, with spirit ammon., aromatic and chloric ether, &c., under which treatment she was greatly relieved of her rheumatic troubles.

Dr. W. Roberts states that the mobility of the kidney is much more common in women than in men, and on the right than the left side. As to its causes, it may be induced by repeated and difficult labours, tight lacing, rapid emaciation in fat persons, a fall, or blow on the loins, jumping from a height, or succussion of the body, &c. He recommends the following treatment:—

"Having first reduced the kidney to its normal position, while the patient is in the recumbent position, apply a tight bandage, or belt, around the abdomen, and if the patient is suffering from anæmia; or any other disorder of the general health to rectify this by ferruginous tonics, shower baths, and to avoid fatiguing exercise, and regulate the bowels by aperient medicine."

Special.

ARMY HOSPITALS IN EGYPT IN 1801 AND 1882.

WHEN, in August, 1801, the Indian contingent of that day joined the British portion of the Egyptian expedition at Ghiza, the sick of the latter were being treated in a general hospital at that place—that is, in accordance with War Office regulations which then existed on the subject of those establishments. In the month of September a considerable part of the combined forces moved to Rosetta. Profiting by his experience in India, the principal medical officer on reaching that place provided separate regimental hospitals

for every corps. In consequence of the occurrence of plague among the troops at Rosetta, their encampment was moved to some distance from the infected locality—a measure, by the way, the credit of which has been unfairly appropriated by “advanced sanitarians,” as they love to call themselves, of the present day. Thatched regimental hospitals were erected for the troops on their new ground, and in those establishments it is on record that, “though in the middle of a desert, the sick soldier had a warm, comfortable, and well-ventilated apartment, and was liberally provided with everything conducive to his recovery.” As the men recovered they were sent to a convalescent camp at a convenient distance from the general camp. This arrangement necessitated the presence of a non-regimental—otherwise a “general”—hospital establishment, so that the “double system” of army hospital administration was worked well and effectually in Egypt in the first year of this century. In the month of November the army was encamped at El Hamed, their sick still accommodated in thatched buildings used as regimental hospitals. A good deal of illness prevailed in the forces at the time, but “the mortality bore but a small proportion to the sickness.” Subsequently, a portion of the army returned to Alexandria. Plague having severely broken out among the forces there, as also among those occupying Rosetta, Aboukir, and Ghiza, “infectious hospitals,” or lazarettos, were established at each of those places, this measure showing very clearly the workable and efficient nature of the medical arrangements of that period.

Eighty-one years elapse. In this long interval conditions, or organisation of army hospitals, have been changed, modified, and re-modelled to such a degree that absolutely nothing remains in them of the characters by which, at the date alluded to, and for more than half a century afterwards, they were distinguished. Then an expedition proceeds to Egypt. As on the former occasion, it consists in part of forces from England, and partly of our Indian contingent. As then, also, two kinds of hospital administration are in use; the one, that introduced by the War Office; the other by the Indian Government. The latter, although not precisely in its details the counterpart of that in force in 1801, is yet sufficiently near it to demonstrate how far it was and is suited to the requirements of an army in the field. And according to all the published accounts, excepting such as are official, nothing could exceed the efficiency with which that system did work. That the circumstance is passed over in silence in the published despatches is therefore a matter not readily to be accounted for. As regards the working of the hospitals organised (?) according to the War Office system, the accounts of that system and comments thereon which have appeared in the columns of the daily press bear ample evidence, even when those accounts are sifted of the palpable exaggerations, and in some instances proved misstatements, which they contain. Questions on the subject asked in Parliament, and the part of a Commission of Inquiry being appointed by a War Minister, indicate the measure of importance given to this matter. But as a point of fact no commission or inquiry will result in the slightest good, unless the entire “system” under which army hospitals under the War Office are now being “worked” in service be absolutely and completely swept away. To officers who had abundant experience of the Indian plan of army hospitals the fact was well known that the system, as a system, was as complete and perfect as anything could well be; that successive wars through three quarters of a century had led to this result; and that such details as were still imperfect in it could readily be improved. Let

the fact be borne in mind—and it is commended to the notice of the Commission now sitting—that the “system” which has recently so signally failed in Egypt is as nearly as possible the same as that which, having been found unworkable in India, was there abolished in the year 1798, and which, having broken down at the very commencement of the Peninsular War, was replaced by “the double system” of army medical administration in 1809.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 10, 1882.

The President, Professor LISTER, F.R.S., in the chair.

Mr. GOLDING BIRD narrated a case of

REMOVAL OF A FIBROID TUMOUR, WITH EXTIRPATION OF THE UTERUS, THAT HAD ENDED FATALLY.

The patient was 37 years of age, and had had the tumour for 3 years. Its increasing size, the pain and weight accompanying it, and the repeated and prolonged attacks of nausea with which it was accompanied, compelled her to seek surgical relief. The tumour—the size of the uterus at six months—grew from the anterior wall of the cervix, and lay between this and the bladder; to the latter it was intimately connected. The uterus itself was all but drawn out of the pelvis, and the ovaries, both cystic, could be felt through the abdominal parietes. Prior to the operation, however, they were thought bases of the tumour. The operation was fully described, and special mention was made of the use of an “apron” of “green carbolised protective,” well tucked in over the intestines when the abdomen had been opened, whereby they were easily kept out of the way and sheltered from the spray. The tumour had its peritoneal investment circumferentially divided where it was reflected on to the pelvic walls, or viscera, and it was then shelled out from its bed, the broad ligaments being previously divided. The union with the uterus was intimate, and had to be divided, while the fusion of the fibres of the tumour with those of the bladder rendered the separation very difficult. All bleeding was stopped with carbolised silk ligatures, and the edges of the peritoneum, where divided between rectum and bladder, at the completion of the operation, were united with a continuous suture. The uterus and ovaries were removed after the tumour, a pedicle being formed out of the cervix uteri; it was tied in four parts, as in Erichsen’s method of tying navi. Before the closure of the peritoneum, a rent in the bladder had to be carefully sewn up. A catheter was tied in. The general conduct of the case was that of an ovariectomy. For forty-eight hours all went well, and then severe vomiting set in, which eventually exhausted the patient, having continued till the fourth day, when she died. The post-mortem showed repair to have been perfect as far as it had gone. There was no evidence of the urine having passed beyond the bladder. There was no suppuration, and only slight pelvic peritonitis. There did not seem to be enough to account for the vomiting, and the author explained this symptom as depending upon some idiosyncrasy of the patient, inasmuch as, when she had typhoid fever ten years before, vomiting, severe enough to threaten life then, was the most prominent symptom. The specimens removed at the operation, and the parts reserved at the post-mortem, were exhibited.

Mr. KNOWSLEY THORNTON inquired what the pulse rate of the patient was, as it would have an important bearing on the case. He imagined that death was not unusually caused by vomiting for which no apparent reason could be assigned, but which, he had come to the conclusion, was attributable to septic poisoning, notwithstanding that the temperature might not seem to indicate it; but the pulse would afford proof of the fact. It was, he feared, a practice too commonly adopted to operate for the relief of these cases in the manner adopted by Mr. Golding Bird, but such a proceeding could only be justified by the occurrence of excessive hemorrhage, or of symptoms threatening

the life of the patient. In such cases, a few of which undoubtedly did occur, the extra-peritoneal method gave good results, provided the pedicle was kept external, and every precaution against septic poisoning observed. Had removal of the ovaries and ducts been performed in Mr. Bird's case, it was probable that life would have been preserved, for, after much thought, he (Mr. Thornton), had come to concur with Mr. Lawson Tait in his opinion regarding the value of oöphorectomy, which, by diminishing the uterine blood-supply, was attended with much good in fibroid conditions of that organ. In 'no case, he concluded, should hysterectomy be adopted until milder operative proceedings had been tried in vain, and it would be found that highly successful results would in most cases follow removal of the ovaries, as in nearly all of his own cases. Replying to the President, Mr. Thornton said that after removing the uterine appendages in his own cases, cure, as shown by contraction of the tumour, took place.

Mr. GOLDING BIRD said the question of removing the appendages of the uterus simply, had been fully discussed between himself and Mr. Bryant, the latter being strongly in favour of the severer hysterectomy. Owing to the highly excitable, nervous condition of the patient, the pulse could not be relied on to afford any information of value, wherefore the temperature indications were more critically observed.

Mr. CLUTTON on a

CASE OF SPINA BIFIDA.

When three weeks old the infant was brought to St. Thomas's Hospital, and was found to be a well-nourished, healthy child, with the exception of the above imperfection. The spina bifida was situated in the lumbar region, sessile, and with exceedingly thin walls. The impulse when the child cried was very marked, and the aperture in the bony canal large. There was no paralysis of the lower limbs, and the cyst, examined by transmitted light, did not appear to contain the cauda equina. The skin had been so stretched that the walls were quite translucent, and would evidently soon have given way, and allowed the fluid to escape. A week after it was first seen, and when the child was four weeks old, the cyst was injected with a drachm and a-half of Morton's fluid, as little as possible of the contents of the sac being allowed to escape. A pad with collodion, and bandage, completed the treatment. The mother was instructed to keep the baby on its back, to prevent, as far as possible, the gravitation of the fluid into the vertebral canal. The constitutional disturbance was very slight, and on the third day the child was in its usual health. The cyst began immediately to shrink, and by the end of a week the skin was in loose folds. At the end of the third week there was nothing to be felt of the spina bifida except a small puckered lining of cutaneous tissue. Mr. Clutton also added notes of two unsuccessful cases.

Mr. MORRANT BAKER asked if any fluid had been allowed to escape prior to the injection, and in what position the child was laid after the operation? He thought the one good result more than counterbalanced the bad ones.

Mr. PEARCE GOULD inquired whether the covering of the tumour in Case 1 consisted of healthy skin, and further, whether the fluid contained in it was analysed for sugar? Much greater chance of successful treatment presented when the skin was entire. Mr. Gould, commenting on Mr. Clutton's remark to the parents of his second case, that death must ensue in the absence of operative interference, related the history of a child, miserably emaciated, and presenting a spina bifida with the skin over it in a sloughing condition, and which, when brought to him, he refused to operate upon. The sloughing surface in this case eventually healed, and though the child died some time later, the cause was marasmus, and was not directly connected with the tumour.

Mr. BARKER described how he had operated in a case resembling Mr. Clutton's No. 3. He kept the child on its back for a long time after having injected the tumour, no effect being produced by the fluid. The case, after being watched for some weeks, died, the tumour previously bursting.

Mr. HOWARD MARSH narrated a case under his own care, in which a child four months old presented a spina bifida in the lower dorsal region, covered with healthy skin, the tumour increasing in size. One drachm of the iodine solution was injected as the child lay on its side, and was succeeded immediately by alarming collapse, with death sixteen hours

later. Such an operation, Mr. Marsh thought, would not be devoid of risk, and he was astonished at the success attained by it in Dr. Morton's hands. Carefully collected records concerning it would be of great value, but the point apparently to be insisted on were that the child should be on its back during and after the injection, and that the latter should be performed slowly.

Mr. HEATH urged that injection of iodine into the cavities of the brain and cord was not necessarily a fatal proceeding. Sir James Paget, some years ago, injected an iodine solution into a meningocele in a child, and the injection in this case must have reached the brain cavity, without however causing death, for he, Mr. Heath, had seen the child when six or seven years old. Talipes calcaneus was almost invariably associated with such cases, but this fact was unknown to a surgeon with whom Mr. Heath had discussed the subject.

Mr. PARKER showed that one case out of twelve treated by himself was successful, and he inferred that the result would depend on the size and nature of the tumour, and the membrane involved. The skin was intact in his one successful case. He injected half a drachm of the solution every two or three weeks, and had not noticed any ill effects produced in consequence. At the present time he had in his care a child with a spina bifida, from which fluid was oozing; the skin was sloughing over the tumour, and the patient obviously dying. Talipes calcaneus was present, but this deformity was not (Mr. Parker thought) an invariable accompaniment. No visible effect followed injection in the unsuccessful cases.

Mr. GODLEE narrated a case in which, after injection of a small thin-walled spina bifida with one drachm of the iodine solution, the tumour dwindled, and the patient progressed very favourably.

Mr. BENNETT found no effect at all to follow injections in the one case he had treated. Not long ago a child was brought to him to be operated on, but in consequence of its ill condition he refused to interfere at the time, and on the way home the patient died of convulsions. Had he operated the result would probably have been attributed to the injection.

Mr. BAKER referred to a case in his practice in which the tumour underwent consolidation, the patient having lost power over the lower extremities.

Mr. CLUTTON said that in all three of his own cases the child had been placed on its back both during and for some time after the operation; the injection was performed very slowly. The fluid obtained from Case 1 gave the sugar reaction. There was no raw surface on the tumour, but in both the remaining cases patches presented entirely devoid of skin. The varying results of treatment might, he thought, find some explanation in the fact that the external absence of bone did not correspond with the aperture from the cyst to the interior.

Mr. CHRISTOPHER HEATH ON

A CASE OF SEPARATION OF THE EPIPHYSIS OF THE CLAVICLE BY MUSCULAR ACTION.

A boy of 14, whilst raising his arm violently to bowl a cricket, felt something give way at his collar-bone. The inner end of the clavicle was found to be unduly prominent, and presented a sharp edge beneath the skin, quite unlike the smooth end of a bone covered with articular cartilage. The supra-sternal notch was quite distinct, and equally defined on both sides, and a thin lamella could be felt on the right side, intervening between it and the gap caused by the starting forward of the inner end of the clavicle. The treatment consisted in laying the patient down, when the bone at once dipped into place, and it was retained by a plaster of Paris bandage. Mr. Heath referred to the great rarity of the accident, and the diagnosis of it from dislocation of the clavicle, and insisted upon the great utility of the plaster of Paris bandage in fractures of the clavicle and humerus.

Mr. LISTER remarked on the extreme rarity of such cases, but added that the diagnosis in Mr. Heath's example could not be disputed.

Dr. CLIPPINGDALE described a case of dislocation of the clavicle forward, following lateral curvature of the spine which again resulted from a long-standing dislocation of the femur at the hip. The patient was exhibited.

Dr. GOODHART ON
SIX CASES OF DIPHTHERIA TREATED BY THE LOCAL APPLICATION OF BORAX OR BORACIC ACID.

In four a saturated solution of boracic acid in glycerine was

used, the application being made in part by a hand-spray, in part by a laryngeal brush, and as often as every two hours in some cases. In the other two a dilute solution of the glycerinum boracis was used. The first case was a very severe one, and it died from the renal complication on the seventh day, but the boracic acid and glycerine seemed to be so successful in relieving the throat symptoms and in preventing the reformation of membrane that it was determined to try it again. Of the other five three had "croup" as well as membrane on the fauces; one had nasal diphtheria; all had albuminuria. All recovered. Tracheotomy was necessary in one case, and the glycerinum boracis was freely applied to the interior of the trachea and larynx from the wound and to the surface of the wound itself, and it seemed to be very beneficial in loosening, dissolving, and preventing the reformation of membrane. In another case it is believed that tracheotomy would have been necessary had not the rigorous application led to the expulsion of membrane by the mouth. In all cases it seemed to give such relief that very little difficulty was experienced in carrying out the treatment. Both borax and boracic acid have been occasionally in use as a topical application in diphtheria, doubtless for a long time past, but not, so far as is known, with any decided success; nor can it be supposed that any remedy will not often show a good proportion of failures in combating a disease such as this. It is enough to say that these agents are known to be good antiseptics, and their action is harmless when not beneficial, and that they are certainly useful in some cases.

Dr. PHILLIPS added notes on the healthy appearance of the surface left after the removal of the membrane in the first case. In two others, admitted when in *extremis*, the membranes extended too far to admit of any good being done to them.

Dr. B. O'CONNOR said he had been treating diphtheria by the boracic acid method for two years, but without encouraging success. In a few instances good results were obtained, but not better than with sulphurous acid. For adults he recommended the application of chlorate of potassium in solution. He had not observed that the membrane failed to reappear in any case after the first application of any remedial agent whatever.

Dr. LONGHIRST advocated a non-irritating mode of treatment, and urged reliance on Nature's efforts to effect a cure, to which end the least possible amount of local irritation should be resorted to.

Mr. LISTER said that each one would extol his own treatment of such cases; and sometimes he had received marvellous accounts of long series of cures treated without any fatal results. This might seem to support Dr. Longhirst's views, but he thought the local nature of the disease would demand some sort of local treatment. As being the first to introduce the use of boracic acid in antiseptic medicine, he would like to think it worthy of being ranked in the foremost place as an application in diphtheria. In onychia it had been proved to be strongly antiseptic, and it might be mixed in almost any proportion with glycerine by the aid of heat. On the whole, he was disposed to regard the treatment recommended by Dr. Goodhart with favour.

Dr. GOODHART considered that, even though diphtheria was a "constitutional," or blood disease, local treatment would still be desirable.

A committee, consisting of Messrs. Pearce Gould, Clutton, Howard Marsh, and Parker, was, on the recommendation of the President, appointed to report on Dr. Morton's treatment of spina bifida.

The following cases were exhibited "by card":—
1. Transpatellar Fracture of the Knee, by Mr. Golding Bird. 2. Removal of the Tongue and Jaw, by Mr. C. Heath. 3. Spontaneous Dislocation of Clavicle, by Dr. Clippingdale. 4. A Case of McEwen's Operation on Both Knees in a Cripple, by Mr. Keetley.

Dr. PERCY KIDD has been appointed Pathologist and Curator to the Hospital for Consumption and Diseases of the Chest, Brompton.

THE deaths from typhoid fever in Paris last week were still further reduced to 125, against 173, 244, and 250 in the three previous weeks.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Etc. Hauteville, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLIAMS and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 54 dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 15, 1882.

NEW ENTRIES.

COMPARISON of the new entries at the various hospitals for the past three years reveals certain facts which cannot fail to prove both interesting and suggestive at the present time. In London the total entries scheduled as "full" students have been for the current session 634. In 1881 the number was 716, and in 1880 the total reached 778, so that two years ago 148 students more than in October, 1882, commenced the study of medicine at the metropolitan schools. To some extent this may be explained by the greater influx of students to Owens College, actuated by the prospect of a degree in arts or science to be obtained coincidentally with the medical qualification; but principally by reason of the commercial depression recently existing in this country. It is not difficult to understand that business men would be chary of engaging their sons in a career which offered little chance of immediate improvement, or of any livelihood, until the doubtful period of returning prosperity indicated by a revival of trade. That they should, therefore, prefer to see them embark in a professional life is but natural, since this offered, at any rate, no worse outlook than the lately unpromising following of commercial occupations. During the last two years, however, trade has undergone a steady improvement, with the result, as we judge, of absorbing an increasing number of the young men, who in less fortunate times would have been devoted to the services of medicine. But this fact will not serve to explain why certain hospitals, notwithstanding the decrease of total entries, exhibit in the year now current

a considerable increase in the number of their new students as compared with previous winter sessions. Thus the London has on its books for 1882-3, 87 full and 40 special students, or a total of 127. In 1880 the numbers were respectively 84, 53, and 137, but in the following year had fallen only to 74, 50, and 124, while the returns of the three years for apparently the most popular hospital, St. Bartholomew's, presents the following curious arrangement :—

Full Entries	...	150	160	110
Special	...	20	6	51
Total	...	170	166	161

At St. Mary's the numbers have risen from 20 in 1881 to 26 in 1882, or, including special entries, 32. Guy's, on the other hand, has steadily maintained a low position during the three years, which are those of its worst troubles. The total of 101 in 1880 fell in 1881 to 84, of whom 81 were full students, and in the present year the entries number 81 full and 15 special.

Those hospitals, viz., the London, Westminster, Charing Cross, and Middlesex, at which the low scale of fees is retained, have probably in consequence been able to maintain their position, but in the case of the first-named the entries are so numerous and so steadily kept up that other causes must undoubtedly operate to give it such favour among students.

King's College offers a most remarkable example of decaying popularity, judged by the returns in question, its entries having been in the three years 69, 56, and 35 respectively. It would be a little difficult, perhaps, but not impossible, to explain this result.

In the following list the returns for 1880, '81, and '82 are given for each metropolitan hospital :—

	1880.		1881.		1882.	
	Full.	Total.	Full.	Total.	Full.	Total.
St. Bartholomew's	150	170	160	166	110	161
London ...	84	137	74	129	87	127
Guy's ...	—	101	81	84	81	96
University ...	—	101	106	147	89	144
St. Thomas's ...	—	91	64	93	62	93
St. George's ...	—	81	63	66	42	48
King's College ...	—	69	56	56	—	35
Middlesex ...	33	50	33	54	37	43
Charing Cross ...	—	45	38	44	41	60
St. Mary's ...	—	20	—	21	26	32
Westminster ...	23	26	—	20	24	25

The number 89 at University is given as *mostly* full, the 55 students having entered for the preliminary scientific classes only. The London Hospital, therefore, easily ranks as second in the list of this year's new entries, not even Guy's being able to claim superiority in respect to numbers. At St. George's there is this year a marked falling off, such as can hardly be accounted for by the causes which have been presumed to influence the total entries; and it cannot fail to be regarded as an indication that, for some reason or other, the school does not preserve its popularity. It is undoubtedly a fact that each year a larger number of University men find their way to the larger hospitals, and as they have in the past been the principal source of supply to St. George's, that

school has suffered in consequence. It cannot be in any way due to faults exhibited in the school itself, for, as far as we can have any means of judging, this is equally as efficient in 1882 as it was in 1880, and yet the entries in the former year are 20 per cent. lower than they were in the latter.

There would seem to be a disposition on the part of new students not to pay the composition fees—a point which is, of course, not brought out in the table above. The fact is, however, sufficiently generally admitted by officials, and may be taken to show that a determination exists to make use of the best teaching facilities wherever offered. If the result is to stimulate competing schools to healthy rivalry, it will be productive of good, and it may be trusted that this will be forthcoming.

We wish particularly to draw attention to the somewhat startling comparisons contained in the table of entries; their meaning may be worthy of further study.

FEVER IN EGYPT, 1801 AND 1882.

It is of interest to recall some particulars with regard to the forms and types of fever which prevailed among the British and Indian troops who occupied Egypt in 1801-2, and compare them, as far as that can be done, with the types and forms of the same general disease which have recently affected our troops in that country. On the first occasion we learn that at different stations, and in different seasons of the year, the prevailing fever assumed different types, although in general character the same; hence in its treatment the same general indication was required to be kept in view. Under different names the same kind of fever was considered to prevail over India and in the tropics generally. In the Presidencies of Madras and Bombay it was known as jungle fever; in Bengal as pukka fever.

In the means of treatment employed are enumerated—Purgation with calomel and the neutral salts; emetics (but these were not always necessary); *venesection*; blisters; diaphoretics; opiates. In severe or protracted cases "the practice always was to endeavour to affect the mouth as speedily as possible with mercury." And what were the results of such unscientific measures? They are thus related :—"This was the practice in continued fever, and in Egypt, as in India, we were very generally successful if application was early made." (a) That is to say, the form of fever which prevailed was looked upon as *sthenic* in its nature, and on that principle treated, with the favourable results here recorded. According to the latest published accounts from Egypt, the form of fever which prevails among the troops occupying Cairo is indicated as "enteric;" its type "most virulent." Soldiers who become affected with that disease are retained at the provisional camp hospital "for a day or two." On arrival at the base hospital they are sometimes delirious and sinking, and several have died a few hours after admission. In the treatment "little or no medicine is given." When the temperature (of the skin) rises to 104° F. and 105° F. "one-drop doses of tincture of aconite" every quarter of an hour for the first two hours, and afterwards every hour, have been found useful. It is the custom to administer

(a) McGrigor's "Medical Sketches," p. 167.

stimulants freely ; to rely on them more than on medicine for treatment ; "and for the rest, nursing—good trained nursing—does more than the doctor towards recovery." As to the particular stimulants available for administration, there occur in the list given, champagne, brandy and soda, port, sherry, "or other extras;" and it is further stated that when patients in hospital affected with the form of fever alluded to "are asked if they will have some brandy and milk, with egg beaten up, they say, 'Yes, sir,' with a gleam of delight in their countenances." The precise words of the report from which the above particulars are taken are:—"In spite of all these luxuries, however, great fatality exists among the *enteric* fever cases." Not one word of comment.

THE GOVERNMENT AND MEDICAL FEES.

THE dispute between the Irish Government and Mr. Wheeler, Vice-President of the Irish College of Surgeons, respecting his remuneration for attending, at the request of Government, upon Mr. Shaen Carter, has occupied Parliament on two occasions last week, and has created so much interest in professional circles that a brief *résumé* of the circumstances is deserving of publication. Mr. Wheeler's claim is for £1,147 18s., and, as this sum might, at first sight, and without knowledge of the facts, be considered unreasonably large, it is right that we should make the profession aware of the services which it represents. On the 15th of March of this year, Mr. Carter was shot at Belmullett, and his knee shattered to pieces; whereupon the Irish Government, on being informed of the occurrence by telegraph, came to the conclusion, as it appears, that the best available surgical aid should be provided. Accordingly, the gentleman who was acting on behalf of the Government called at Mr. Wheeler's house, and, not finding him at home, left a note requesting him to call in all haste at the Castle, which Mr. Wheeler did. The gentleman then informed him of the occurrence, and requested him to go forthwith to see Mr. Carter, adding that, if that gentleman was not able to pay the proper fees, Government would settle them. Mr. Wheeler had then no knowledge as to Mr. Carter's competency to pay, but, acting upon these instructions, he left Dublin the same evening for Belmullett. That place is situated at the extremest north-western point of Ireland, forty-two miles by car, across a sparsely inhabited, almost savage, and greatly disturbed district, to the nearest railway station (Ballina). This journey occupies seven hours going, and seven returning, and he (Mr. Wheeler) had to be guarded on each occasion by constabulary on the car, while the journey had to be performed on an open vehicle, mostly at night, and in any weather which happened to present itself. The railway travelling from Dublin to Ballina occupied alone eight hours going and the same returning, so that any person requiring to go to Belmullett and back, from Dublin, must travel for two nights and a day continuously, without taking any legitimate rest whatever. It is, therefore, evident that the services which the Government required from Mr. Wheeler were, even when viewed as a matter of physical labour, such as no elderly or delicate person could attempt to perform, and

such as would severely strain the endurance of the most robust and energetic.

Arrived at Belmullett, Mr. Wheeler seems to have at once ascertained three facts—first, that Mr. Carter's leg must come off; second, that the operation could not be done until shock had passed away; third, that Mr. Carter could pay no fees whatever; and it has since been stated that he had no other means of maintaining himself and his family than about £200 a year of unpaid rents.

Therefore, having done all that was expedient or possible for the patient, Mr. Wheeler returned to Dublin, and on the day of his return went to the Castle and reported the state of affairs to the same official, informing him that, in his opinion, Mr. Carter would need an operation and several visits, and that, as the patient was quite unable to pay any part of the fees, he required to know whether the Government wished him to continue his attendance. He was asked what his fee would be, and he named 125 guineas a visit; and on being told that £100 was the fee last paid by Government, he replied that he could not accept less than the fee he had named, considering the distance to be travelled and the time lost. Mr. Wheeler was then requested to call back in a couple of hours, so that his proposal might be submitted to the superior authorities of the Government. Having done so, he received a written memorandum to the effect that, if Mr. Carter were unable to pay, he (Mr. Wheeler) might submit his claim for such attendance to the Government, and it would receive favourable consideration. This guarantee, coming as it did immediately after Mr. Wheeler's definite refusal to accept less than the fee he considered adequate, induced that gentleman to go again to Belmullett three days subsequently. Finding Mr. Carter still unfit for operation he was obliged to return to town, but, a few days afterwards, he went again to Belmullett, bringing with him two assistants, and amputated the leg. It is not necessary to pursue the history of the transaction further than to say that, as soon as Mr. Carter was fit to be moved, Mr. Wheeler went down and brought him to Ballina, where he visited him once subsequently on a threatening of pyæmia, and that he afterwards brought him to Dublin and visited him there over 100 times, until he was well. Altogether, he made five visits to Belmullett between the 15th of March and 8th of April, operated, remained eight days in attendance, escorted him to Ballina, and visited him twice there, brought him to Dublin and attended him daily there for nearly three months, and paid all his own expenses.

We are very decidedly of opinion that, considering the time lost, the physical labour endured, the danger to life and health repeatedly incurred by a journey at such time of year, through such a country, and in the midst of agrarian anarchy, and the professional income sacrificed by a surgeon of Mr. Wheeler's position, being absent from his business for long periods, the claim submitted by Mr. Wheeler was quite reasonable in amount, assuming—as we do—that all the attendances were *bona fide* and necessary.

No surgeon occupying the position of Vice-President of the Royal College of Surgeons in Ireland ought to accept a much less sum under similar circumstances,

and any surgeon of decent position might reasonably demand as much. But it appears to us that the amount of the fees claimed is not in question at all, nor the number of visits paid, because both of these matters were fully under the notice of the Government throughout the entire transaction, and met with no objection whatever on their behalf. Mr. Wheeler's claim would, indeed, be open to dispute if he had—on the first authorisation which he received—continued to visit Mr. Carter without the further knowledge or assent of Government, and afterwards laid his claim for unknown and semi-authorised services. But he did nothing of the sort; on the contrary, he reported each visit in writing regularly, and stated his intention to visit again, and his reasons therefor, and in each case he received an official acknowledgment of his report.

It was open to the Government to have stopped his visits and his remuneration at any moment, and their official memory was continually jogged both by letters and verbal reports, yet they continued their assent to the transaction, and we do not see on what principle they can now attempt to repudiate the claim.

It is not our function to express an opinion as to the action of the Irish Government in seeking to transfer their own legitimate responsibilities to Mr. Carter. That aspect of the transaction will be dealt with, no doubt, in Parliament and in the courts of law. It is our duty simply to defend the profession against an innuendo of extortion, and we think the facts we have narrated make such defence unnecessary.

Notes on Current Topics.

National Decay.

THE visit paid by Mr. Herbert Spencer to America will, if the warnings uttered by the synthetic philosopher are taken to heart, result in untold benefit to the people directly addressed. In an after-dinner speech delivered on the day before his departure for England, Mr. Spencer indicated the weakness of the American nation, and that peculiarity of its constitution which will, unless assiduously repressed, ultimately tend to its enfeeblement and effacement. He alluded to the passion for work exhibited by all Americans, which, in some cases, leads to the death of individuals under the pressure to which they voluntarily submit. The hair with them is grey ten years before this is the case in England, and relaxation is regarded as a physical impossibility. The result is to impair the physique of the nation, and the evil becomes increasingly serious with each generation. As Mr. Spencer very properly insisted, a man's constitution should be regarded as an entailed estate, and employed with the same precautions and references to future necessities. An excess of labour is irrational, and as useless as the hoarded treasures of the miser, and there is much wisdom in the advice given to his entertainers by Mr. Spencer, who bade them accept and preach abroad the gospel of relaxation, without the influence of which he hinted it was impossible for the great American people to aid in the development of the great future in store for the nation. It is, of course, pleasant to know that our native philosopher is putting

his talents to such good use, but we should be equally well pleased if, on his return, he will exhibit at least as much concern in the welfare and advancement of our own country as he has shown on behalf of our Transatlantic cousins. They sometimes complain of the officiousness shown by Englishmen in attempting to reform or improve them. Occasionally, it must be admitted, they have cause for doing so.

The Dangers of the Ambulance Movement.

It is not so generally recognised in this country as it might be that abroad the above-named movement has not met with the enthusiastic—not to say gushing—reception that has here been accorded to it. Medical practitioners and medical journalists have seen in the movement, or have thought they have seen, the germs of a widely-spread quackery. They say, educate these working men in surgery up to a certain point, and a great number of them will be quite ready to set up as surgeons on their own account. It is impossible to say that this will not be the case. Professor Esmarch, in Germany, has met with great opposition in his championship of the movement; in fact, the general expression of disapproval at his conduct has been so decided, that he is said to be on the point of withdrawing from it. The subject was recently discussed at the Medical Society of Rostock, when the following theses were accepted:—1. The training of the laity for first help to the wounded, after the manner of Esmarch's instructions, may be of service if limited to what is indispensable, and if the dangers of misconceptions or over-stepping of limits are distinctly pointed out. 2. Public Samaritan schools, open to every one, appear very dangerous. The participation in such training should be limited to such as give sufficient guarantee by their character, education, and calling, and it is to be recommended for police, harbour, and railway officials, fire-police, overseers of factories, seamen, &c. 3. Examination of pupils, with distribution of diplomas, is highly objectionable.

A New Physiological Work.

ARRANGEMENTS have been made by the authorities of the Clarendon Press at Oxford for the purpose of obtaining English translations of Continental biological works in the shape of memoirs and treatises, and which are not now available, except in the original language of their authors. The important and onerous task of editing these publications has been committed to Professor Michael Foster, Dr. Pye-Smith, and Dr. Burdon Sanderson, and the first work to be undertaken is a volume of some 750 pages, to consist of three separate parts, each complete in itself. The treatises selected to this end are one by Heidenhain on the "Physiology of Secretion," already familiar by reputation to every reader of modern text-books of physiology; a second, by Professor Goltz, consisting of four papers, on the "Functions of the Brain," together with a memoir on the "Excitatory and Inhibitory Processes in the Motor Centres of the Brain," by Heidenhain and Bubnoff; and the third, Prof. Engelmann's papers on "The Structure and Physiology of the Elementary Contractile Tissues." We are uninformed respecting the time when these important contributions to our literature may be

expected; but having once been promised, and all the essential arrangements for their production made, it is to be hoped nothing may intervene to defer unduly the pleasure that English students will experience in the perusal of these classical works.

Cæsarean Section *versus* Porro's Operation.

DR. M. SANGER, of Leipzig, has been recently vigorously defending the classical Cæsarean section against Porro's operation. In an article in the *Archiv für Gynäkologie*, No. 19, he rejects the fashionable operation, and places all his reliance on its venerable—even almost defunct—rival, expressing his confident belief that, with antiseptic precautions and a better method of suturing, the best results will be obtained by the old operation. He recommends a median longitudinal incision, or, if the placenta be in front, a transverse one through the lower segment of the uterus, or even through the anterior cervical wall. Before uniting the edges of the wound, he slices off some of the edge from each side, so as to leave a narrow strip of over-lapping peritonæum. He uses two sets of stitches, the first entirely muscular, and the second entirely serous. By this manœuvre he believes he avoids separation of the adhesions that will form between the two peritoneal layers by uterine contractions. He does not include the decidua in the sutures. The article itself is well worth reading.

The Royal Society.

THE medals in the gift of the Council of the Royal Society have just been awarded for the present year. Among the recipients is Prof. W. H. Flower, F.R.S., to whom a Royal Medal is given for contributions to the morphology and classification of the mammalia, and to anthropology. The other medals were awarded thus:—The Copley Medal to Professor Cayley, F.R.S., for his researches in pure mathematics; the Rumford Medal to Captain Abney, F.R.S., for his photographic researches and his discovery of the method of photographing the less refrangible part of the spectrum, especially the infra-red region; a Royal Medal to Lord Rayleigh, F.R.S., for his papers in mathematical and experimental physics; the Davy Medal (in duplicate) to D. Mendelejeff and Lothar Meyer, for their discovery of the periodic relations of the atomic weights. These medals will be presented at the anniversary meeting of the Society on St. Andrew's Day.

The Quarterly Return of the Registrar General.

DURING the three months ending 20th September last 280,216 children were born in the United Kingdom, and the number of deaths registered reached 153,343, thus giving a recorded increase of population equal to 126,873. In England and Wales 118,114 deaths took place, of which number 32,952 were infants under twelve months old, and 26,929 were of persons over 60 years of age. 20,825 deaths occurred through zymotic diseases, the most fatal of them being diarrhoea, scarlet fever, and whooping cough, while 209 cases of small-pox are recorded. The death-rate from all causes was 17·7 per 1,000, which is no less than 1·5 per 1,000 below the average for the corresponding quarter in the last ten years. In London the rate was

18·6, the rate for the 28 great towns being 20·6. Sunderland gave the highest figure, 28·3; Brighton gives 17·8; while Derby reaches only to 14·9. The causes of death were duly certified in 90·8 per cent. of the total, 5·4 per cent. by coroners in inquest cases, and the remaining 3·8 per cent. were uncertified. London contributed only 1·2 per cent. of such deaths in proportion, but the rest of England and Wales 4·3 per cent. Wales (9·9 per cent.), Durham (6·9), Cumberland (6·7), and Cornwall were the places which returned the greatest number of uncertified deaths, while in Wolverhampton the figure (9·2) recorded is nearly double the proportion which prevailed in either of the last two quarters of the year.

The Prophylaxis of Blennorrhœa Neonatorum.

DR. KÖNIGSTEIN, of Vienna, recommends in the *Archiv für Kinderheilkunde*, for the avoidance of the above dangerous affection, that the child's eyes, immediately after separation of the umbilical cord, shall be bathed, a clean rag being used, and then that a drop of a 2 per cent. solution of nitrate of silver be dropped into each eye. Most will acknowledge that the plan would be likely to prove effective; but are such severe measures necessary?

Royal University of Ireland.

ON Wednesday afternoon last the first assembly of the Royal University was held, for the purpose of conferring degrees. The assembly was very numerous and brilliant. Being the first ceremony of this kind since the establishment of the University, great interest was attached to it, and several of the nobility and nearly all the leading literary men of the country were present. The Duke of Abercorn, who presided, having referred to the origin of the University in 1879, and the Act incorporating it, introduced in the House of Lords by Earl Cairns, proceeded as follows:—

I much regret that it falls to my lot to record that very shortly after the commencement of our labours, and before any results had yet appeared, one of our body was removed by death. Dr. Hayden was a physician of great eminence in his profession, and of remarkable ability, and his colleagues all feel the loss which has been occasioned by his removal from amongst us. Two others of those who were named as the First Senators having tendered to Her Majesty their resignation of their places, there exist now upon our Senate three vacancies, the first and third of which are shortly to be filled up by the election of members by Convocation and to the other the appointment rests under the Charter with the Crown. On the 3rd February of the present year, the Queen's University in Ireland was dissolved. We, therefore, in the months of June and July last, held the usual examinations in the Faculty of Medicine. The number of candidates who entered for these examinations was 307, and of these 167 satisfied the examiners in the various subjects in which they had presented themselves. As a result of the degree examinations then held, the Senate, on 13th July, admitted to the Degree of Doctor of Medicine twenty-nine gentlemen, and to that of Master of Surgery, twenty-eight; and they awarded the University Diploma in Obstetrics to fourteen. The greater number of those who obtained the degree of M.Ch., and the Diploma in Obstetrics were amongst the twenty-nine on whom the degree of M.D. was also conferred. The Senate immediately upon the passing of the Endowment Act, proceeded to frame the statutes necessary for the government of the University, and upon the 10th November, 1881, they submitted to her Majesty the statutes

which they deemed it expedient should be enacted, and upon the 29th of the same month, her Majesty was graciously pleased to approve thereof under the Sign Manual, and thereupon the statutes became the law of this University. No time was lost by the Senate in throwing open to the people of this country the benefits which the Legislature intended for them, and on the 6th December, 1881, the first matriculation examination of our University was held. For that examination the extremely large number of 728 persons entered themselves as candidates; 614 actually presented themselves for examination, and of those 508 were reported by the examiners as qualified to pass, 114 obtaining places upon the honour lists in one or more subjects, and to the most distinguished of whom there were awarded 10 first-class exhibitions of £24 each, and 20 second-class exhibitions of £12 each. A further special examination to which only candidates who had obtained honours were admissible was then held, and six University scholarships of the annual value of £50 each, and tenable for three years, were awarded, two in classics, and one in mathematics, and two in modern literature. It now only remains for me to mention very briefly the statistics of the annual examinations which have been recently held. The entire number of candidates was 1,515, viz., 11 in the Faculty of Law; 519 in the Faculty of Medicine; 350 in the Faculty of Arts; 27 in the School of Engineering, and 608 for Matriculation; of that number there have passed, in the Faculty of Law 10, in the Faculty of Medicine 256, in the Faculty of Arts 251, in the School of Engineering 17, and for Matriculation 487. Honours have been awarded to 4 of the candidates in the Faculty of Law, to 13 in the Faculty of Medicine, to 97 in the Faculty of Arts, to 4 in the School of Engineering, and to 82 at the Matriculation. We have also awarded to the most distinguished answerers at the various examinations, a large number of valuable prizes and exhibitions, ranging from £50 down to £12 each. Some of those exhibitions and prizes have been adjudged to students who are this day to receive the degrees to which they have attained, others go to candidates who are still in, or are just entering upon the career of undergraduates, and they will, we hope, serve as incentives to further exertion.

The Medico-Psychological Association.

THE usual quarterly meeting of this Association was held at Bethlem Hospital on Wednesday evening, the 8th November. In the absence of the President the chair was taken by Dr. D. Hack Tuke. Dr. Mercier read a paper on "The Conditions of Life affecting Insanity," and Dr. Julius Mickle communicated some particulars on "Traumatic General Paralysis." Interesting discussion followed in each case, and owing to the lateness of the hour, a paper by Dr. Fletcher Black on "Atrophy of the Brain" was taken as read.

Regeneration of Divided Nerves.

DR. POST (*Phil. Med. Reporter*) says that, with regard to the restoration of function of divided nerves, there is a difference between the nerves of sensation and those of motion, restoration taking place to a much greater degree in the function of sensation than in that of motion. When the motor nerves have been divided there is much less chance of the patient regaining lost power of function than there is in the case of sensation. It would seem that there is more active nervous power required for a nerve of motion than for one of sensation. At all events, the fact, I believe, is a general one, that the restoration of motor power is much less perfect than that of sensation.

The Medical Department and the Military Ring.

AT this time when the Medical Department has been made the subject of unqualified depreciation by military officers, whose sudden change from the enervating influences of London life to the rough usages of war, has led them to suppose that the hardships which have made such an impression upon them must be due to some one's fault, and not to the realities of active service, it will be but wise to lay bare all questions which jar in the relations of military and medical officers, and even at the risk of being deemed hypercritical, we would venture to put in words a galling disappointment which is in direct ratio to the loyalty of these officers to their royal mistress. We need go back for precedent no further than the little wars of recent date—the Cape, Zulu, Boer, and Afghan—and we believe we are correct in stating that in no instance, on the return of the troops from these campaigns, has the Principal, or other medical officer, whether the recipient of a C.B. or V.C., been honoured with a command to the royal table. That the Sovereign sympathises with a woman's heart in the sorrows of her people, and the sufferings of her soldiers, is the true source of the nation's love. It is not, therefore, indifference to the Throne that prevents the officer best qualified to afford the fullest information from being called to render a personal account to his Sovereign. What is it? Is there anything in the social position of the medical officer to disqualify him from the privilege of personal communication with his Queen? If so, let it be so laid down by the arbiter of fitness without fear or shuffling. If not, there must be some explanation of the fact that, while military officers of every degree receive official recognition of public services by being summoned to the Sovereign's presence, the medical officers of the highest rank are only permitted to impart the history of their anxious efforts for the care of the sick and wounded through some favoured member of the military ring that still surrounds the Throne.

An American Naval Museum of Hygiene.

THE Bureau of Medicine and Surgery of the United States Navy, is about to establish a naval Museum of Hygiene. The plan proposed comprehends a collection that shall be illustrative of the entire range of sanitary science, the establishment of a course of lectures by authoritative sanitarians from all sections of the country, and a library of sanitary science accessible, under proper restrictions and guarantees, to all who are engaged in the study of this branch of knowledge. This library already numbers many of the standard sanitary works in the English, French and German languages, and is constantly increasing. It is an admirable undertaking, and we doubt not will be heartily welcomed by both the staff and the profession at large.

MR. A. PEARCE GOULD, F.R.C.S., has been elected Assistant-Surgeon, in the room of the late Mr. Lyell. Mr. Gould has been for the past five years Assistant-Surgeon and Lecturer on Anatomy at the Westminster Hospital, which he leaves for the larger sphere of the Middlesex.

Baths Eau Naturelle.

PROFESSOR JOHN STUART BLACKIE paints in seductive colours, in the current number of *Blackwood*, the charms of the bath in which he is wont to disport himself, which consists of an "amber rock caldron," fenced round with granite walls, festooned with ferns, overhung with feathery trees, and canopied by the blue cloud-flecked sky. Into this picturesque basin "the foamy torrent falls," and there the learned Professor invites his friends to come instead of tainting their skins "with swathes of drumly German mud." He urges them to plunge boldly into the "liquid topaz fair," and to indulge in a number of aquatic exercises, such as giving their backs to the spout that comes so bravely down, floating upon the swirling flood, and dashing and splashing in emulation of a trout. The Professor's verses are bright and refreshing, and conjure up delicious recollection of mountain torrents "beneath the purple brae," and it is because we hope to have many more such verses from his vigorous and graceful pen that we express the hope that he has been describing to us some poetical vision, and not his actual practice. It would be the height of rashness for any elderly gentleman to adopt his advice and take his bath while sojourning in Scotland in the manner recommended. There are very few days in the year in Scotland when even middle-aged gentlemen could without risk plunge into a pool and allow a tremendous douche of cold water to dash down the spinal column. After forty years of age, it should always be borne in mind, the tissues lose their elasticity and resiliency, and become, if we may so say, more rigid and brittle. They cannot, with the same celerity as in youth, adapt themselves to sudden changes in external conditions, and shocks of all kinds become hazardous. Paralysis has not seldom dated from the sudden exposure of the surface to cold. Long may Professor Blackie sing of baths *eaux naturelles*, while he contents himself in reality with a tub of tepid water in a well-warmed dressing-room.

Hygienic Treatment of Albuminuria.

At the inaugural meeting of the Berlin Medical Society for the present session, Herr Senator read a paper on "The Hygienic Treatment of Albuminuria." The author had met with but scanty success in the use of tannin, acetate of lead, fuchsin, or turpentine; one might perhaps credit iodide of potassium with a certain amount of value. The hygienic treatment of the affection, on the other hand, he considered not without good results. Two points should particularly be kept in view, viz.:—First, digestion itself; and second, the kind of food to be given. With regard to the first it should be borne in mind that in many cases albumen will appear in the urine after food of any kind. With regard to food, eggs have an injurious effect. Even after the eggs have been cooked, albumen has appeared in the urine. He considers that the recommendation to patients the subjects of albuminuria to consume large quantities of eggs, meat, and cheese should be completely reversed. He would at least advise that meat poor in albumen (the so-called white meats) and fish should be given. In addition he recommended an increased consumption of vegetables. He thought alcoholic beverages as a whole injurious, but he did not prohibit them altogether. He permitted red wine; beer he considered more injurious. Milk he recom-

mended. Two litres of milk daily would contain nearly all the albumen necessary for nutrition, 70 grms.; 85 grms. being the amount said to be necessary by Voit. Warm clothing he considered indispensable; and confinement to bed had the further advantage of excluding muscular movement. By the treatment he recommended no brilliant results would indeed be achieved, but in a great part of the cases an improvement would be brought about, or even a transient disappearance of the albuminuria.

Civic Grants to Dublin Hospitals.

A SPECIAL meeting of the Corporation of Dublin was held in the Council Chamber of the City Hall on Monday, October 23rd, when, among other business, the annual presentations in aid of the metropolitan hospitals were made, as follows, to the total amount of 4,595*l.*, viz.:—Mercer's Hospital 300*l.*, Jervis Street Hospital 300*l.*, Hospital for Incurables 300*l.*, St. Mark's Ophthalmic Hospital 150*l.*, City of Dublin Hospital 300*l.*, Coombe Lying-in Hospital 520*l.*, St. Vincent's Hospital 400*l.*, Meath Hospital 300*l.*, Mater Misericordiae Hospital 400*l.*, Sir Patrick Dun's Hospital 300*l.*, Maternity of Sir Patrick Dun's Hospital 50*l.*, Rotunda Lying-in Hospital 300*l.*, Cork Street Fever Hospital 300*l.*, National Orthopaedic Hospital of Ireland 100*l.*, Dublin Orthopaedic Hospital 100*l.*, Chrildens' Hospital, Upper Temple Street 150*l.*, Steeven's Hospital 150*l.*, National Eye and Ear Infirmary 100*l.*, Throat and Ear Hospital 25*l.*, Hospice for the Sick and Dying, Harold's Cross 150*l.*

Quinia Sulphate in Pruritus.

DR. STEELE, of Denver (*Lancet and Clinic*), has found quinia sulphate, rubbed up with only sufficient lard to hold it together, a specific for pruritus. He uses it in both pruritus ani and vulvæ. The nearer you get to the full strength of the quinine, the more efficacious it will prove.

The Egyptian Gazette.

In the *Gazette* recently published, Sir Garnet Wolseley selects several officers of the medical staff for special commendation. "Brigade-Surgeon Jackson, O.B.," the *Gazette* says, "who has seen service in all parts of the world, has, through the many wars he has taken part in, distinguished himself throughout by his coolness under fire, and in zeal as a medical officer. I would venture to recommend him for special promotion." The same document also states:—"The Medical Department under Surgeon-General Hanbury, O.B., have done everything that could possibly be done for the care and comfort of the sick and wounded. The manner in which the sick and wounded were removed from the fighting line by the bearer company was most satisfactory. The following officers are brought specially to my notice:—Deputy Surgeon-General J. Ekin, Deputy Surgeon-General W. G. N. Manley, V.C., Deputy Surgeon-General J. A. Marston, Brigade-Surgeon O. Barnett, Surgeon-Major G. S. Davis, and Surgeon-Major T. F. Dwyer."

DR. J. BRAXTON HICKS has been appointed Honorary Fellow of the Edinburgh Obstetrical Society.

It is announced that the honour of knighthood will be conferred on Mr. Oscar Clayton, F.R.C.S., in recognition of services rendered by him to the Prince of Wales.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Brighton 15; Huddersfield 16; Newcastle-on-Tyne, Cardiff, Birkenhead, Plymouth, Leicester 17; Birmingham, Sheffield 18; Blackburn, Bristol, Bolton 19; London, Dublin, Nottingham 20; Leeds 21; Edinburgh, Bradford, Halifax 22; Manchester, Salford 23; Portsmouth, Hull, Norwich 24; Glasgow, Oldham, Derby 26; Sunderland 28; Liverpool 29; Preston 33.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 26, Bombay 27, Madras 35; Paris 23; Brussels 18; Amsterdam 21; Rotterdam 17; The Hague 19; Stockholm 18; Christiania 14; St. Petersburg 42; Berlin 23; Hamburg 19; Dresden 22, Breslau 28, Munich 26, Vienna 21, Prague 29, Buda-Pesth 24, Trieste 25; Naples 27, Turin 18, Venice 31; New York 21, Brooklyn 20, Philadelphia 17, and Baltimore 22.

THE annual death-rates per 1,000 in the larger towns last week, from diseases of the zymotic class, were:—From scarlet fever, 2.6 in Sunderland, and 1.8 in Sheffield; from measles, 5.3 in Sunderland and 1.2 in Norwich; from whooping-cough, 3.7 in Preston and 1.3 in Bradford; and from fever, 2.2 in Sunderland, 1.9 in Derby, and 1.2 in Portsmouth. The 31 deaths from diphtheria included 13 in London, 7 in Glasgow, and 3 in Edinburgh. Small-pox caused one death in the outer ring of suburban districts around London, one in Manchester and one in Newcastle-upon-Tyne.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

PRESENTATION TO DR. THOMAS, OF THE ROYAL INFIRMARY, GLASGOW.—An interesting occurrence took place at the Royal Infirmary, Glasgow, on the 9th inst. The nurses of the institution, desirous of testifying their esteem and regard for Dr. Thomas, who has for upwards of 15 years so worthily filled the office of superintendent of the hospital, resolved to present him with a suitable testimonial. Mr. William M'Ewen having been asked to take the chair, called upon Dr. Scott Orr to make the presentation. Dr. Scott Orr, after a brief account of the establishment of the office of medical superintendent in the year 1848, when he himself was the first appointed to hold it, paid a high compliment to Dr. Thomas for the very efficient manner in which he had for so many years discharged the numerous and yearly-increasing duties which devolved upon him, and spoke of his urbanity and courtesy, his discretion and kindness. He then presented him with a large and very handsome silver tray, having a suitable inscription, from the nurses of the Infirmary, in proof of their great regard for him, their high sense of the efficient manner in which his numerous duties were performed, and as a token of their appreciation of the kindness with which he always regarded

their interests and comfort. Dr. Thomas having made a suitable reply, and after a few remarks from the chairman, the meeting separated.

NEW FEVER HOSPITAL FOR EDINBURGH.—At a meeting of a Committee of the Edinburgh Town Council, held on the 6th inst., a joint report by the Medical Officer and City Superintendent on the proposed new Fever Hospital for the city was submitted. It embraced a scheme whereby the entire surgical hospital might be utilised as an epidemic hospital for those classes of diseases which were not received into the fever house belonging to the managers of the Infirmary. In the report provision was made for securing entire isolation of small-pox patients; for affording accommodation for the better class of citizens, who for payment might desire isolation and treatment in a well-conducted hospital; for observation wards, the exact nature of the arrangements for which, however, was not determined; and for the families turned out of infected houses, or "quarantine wards." The report was generally approved.

PROFESSOR BELL PETTIGREW ON SCIENCE TEACHING.—Professor Pettigrew, F.R.S., chose for the theme of his recent introductory lecture in physiology at the University of St. Andrew's, "Creation: Man's Place in Creation, his Education and Development, from a Science Point of View." The lecture, which was illustrated by a large number of beautiful diagrams, was numerously attended, and listened to with marked attention. The Professor, after discussing the various theories of the formation of the universe and the origin of man, said the burning question of the day was education. The ancients believed, and he thought rightly, that men varied as to intellectual capacity and endowment, and that it was the province of education to draw out of the man that which naturally inhered in him. The more modern, and he believed the less philosophic view, takes for granted that men vary little to begin with, and that everything might be put into them by a process of cramming. The ancients aimed at teaching men to think and judge; the moderns had no soul above passing examinations and getting on in the world. As a physiologist, his sympathies were wholly with the ancients. The great problem of the day was how to develop and cultivate the human intellect. The two great modern schools of education were, he said, widely divergent. The one sought, by symbol and cipher, to impart to the young and inexperienced head abstract ideas and truths about men and things; the other aimed at instructing youth not by symbols and the mere names of things, but by the things themselves—these, fortunately for science, being strewn around in prodigal profusion. The former method—the symbol teaching—leans principally upon memory, and is eminently unattractive to the young mind. It has, as a consequence, proved a comparative failure. The latter method—the object lesson method—is quite a seduction for children. It leans less—indeed, comparatively little—on memory, and provokes thought and reflection. The object lesson method expands the reason, and develops and corrects the judgment. He could not conceive anything more painful than a child endeavouring to understand and remember a thing he had never seen, and of which even his teacher, from the faulty system of education at present in vogue, had a very hazy conception. The vicious system of teaching which degraded the schools also degraded, within certain limits and with certain exceptions, the universities, and especially our much cherished and boasted Scottish Universities. As science could only be properly taught in the laboratory, it was sincerely to be hoped that the promised forthcoming Executive Commission would deal liberally with the Scottish Universities in

everything that pertained to laboratories and practical science teaching.

HANDSOME GIFT TO ABERDEEN UNIVERSITY.—At a meeting of the Senatus of the University of Aberdeen, held on the 4th inst., it was intimated that the sum of £8,000 had been placed at the disposal of the University authorities by Mr. George Thomson, junr., of Pitmedden, for the purpose of founding bursaries in the Medical Faculty. It was unanimously resolved to accept the gift and to tender the warmest thanks to the donor. The same gentlemen a few weeks ago handed over the sum of £4,000 for distribution among the most prominent of the Aberdeen charities.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 4th inst., the mortality in Edinburgh rose from 77 to 96, and the death-rate was 22 per 1,000. Diseases of the chest accounted for 50 deaths, and zymotic causes for 6 of which 1 was due to fever, 1 to diphtheria, and 4 to scarlatina; the intimations of those diseases being respectively 13, 14, and 61.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday were at the rate of 26 per 1,000 per annum, against the same number last week, and 25, 29, and 22 in the corresponding periods of 1881, 1880, and 1879.

NEW CHAIR OF PATHOLOGY AT ABERDEEN.—At a meeting of the Senatus of the University of Aberdeen, recently held, a deputation of students was heard regarding attendance upon the new Chair of Pathology in the University, the object of their representation being that the study of Pathology and Medicine should be combined, as they have been hitherto. The Senatus, after hearing a statement of the case on behalf of the students, resolved to intimate their decision in writing.

DALKEITH.—ERECTION OF A HOSPITAL BY THE DUKE OF BUCCLEUCH.—A hospital for Dalkeith, which has been erected at Newmills at the expense of the Duke of Buccleuch, and nominally handed over to the Commissioners of Police as Local Authority for the use of the inhabitants, was opened recently for the inspection of the public previous to occupation. The new hospital is a handsome building of two storeys, the upper flat of which is divided into airy and commodious wards, capable of accommodating from forty to fifty in-patients. The wards are so arranged that cases of infectious disease can be isolated, separate entrances and staircases having been provided for that purpose. The under flat is entirely devoted to nurses' accommodation, baths, and other necessary offices. Particular attention has been paid to the ventilation and drainage of the whole building. The water-closets are ventilated into the open-air, and there is a complete system of drainage from the outside to the river Esk.

Literary Notes and Gossip.

WE understand that Dr. Charles Cameron, M.P., is about to publish in book form a paper he lately read before the Philosophical Society of Glasgow, in which he pointed out the strong analogies in, and the close relationship between, the minute organisms believed by some to be the active causes of putrefaction, disease, and fermentation.

A REVIEW of the late Professor Spence's "Lectures on Surgery" appears in the *Scotsman* of the 11th inst. We wonder what our professional Puritans have to say to this egregious departure from "medical ethics"—a science devised to protect those born in the purple and repress the just and legitimate claims of those who have not been so fortunate.

A NEW and enlarged edition of Otto Spiegelberg's "Hand-book of Obstetrics for Practitioners and Students" (*Handbuch der Geburtshilfe für Aerzte und Studierende*), has recently been issued by Lahr, of Schanenberg. A part of the work (the chapters devoted to puerperal fever and obstetrical operations) has been revised by a friend of the author—Dr. Wiener. It is said to sustain in every way the reputation of the previous edition.

THE *Centralblatt für Klinische Medizin*, hitherto published by Rühle and Finkler, of Bonn, will henceforth appear from the office of Breitkopf and Haertel, of Leipzig, and, as the title-page announces, will be published by Professors Frerichs, Gerhardt, Leyden, Liebermeister, Nothnagel, Rühle; and director, Dr. Struck; and edited by Professors Brieger, Ehrlick, Finkler, and Dr. A. Fränkel. It is intended that, as heretofore, the paper shall represent the department of "Medicine."

THE College of Physicians of Philadelphia offers the sum of twenty-five dollars, or a gold medal, to be awarded at the first meeting in April, for the best pathological report, with or without specimens, read before April 1st, 1883, by any member of the Society who, at the time of presentation, shall hold the position of Resident in a hospital. This is following the example of the Dublin Pathological Society, which, for many years, granted a gold medal for a prize essay written by a student. The award has, however, been discontinued of late.

ANATOMICAL enthusiasts will welcome the appearance of a new edition of Quain's Anatomy, and general satisfaction will be created by the improvements introduced into the work. The sections dealing with the vascular system are enriched in this edition with coloured engravings, which add much to the value and clearness of the work, while, under the able supervision of Dr. Allen Thompson and Messrs. Schäfer and Thane, the whole of the text is brought fully abreast of all the latest discoveries. For the higher examinations in anatomy it is indispensable and invaluable.

THE Index Catalogue of the Library of the Surgeon-General's Office at Washington, U.S.A., is now advanced to the end of the third volume, and to the completion of the letter D. This last instalment of the great undertaking committed to the care of Dr. Billings by the United States Government, includes 9,043 author-titles, representing 10,076 volumes and 7,386 pamphlets. It also includes 8,572 subject-titles of separate books and pamphlets, and 23,846 titles of articles in periodicals. The volume also catalogues 4,335 medical portraits, and certainly derives much interest from this fact. We heartily congratulate Dr. Billings on the progress of his incomparable labours.

MESSRS. LONGMAN AND CO. are to be congratulated on the publication of the "Dictionary of Medicine," edited by Dr. Quain, the issue of which within the last few days marks an era in medical literature. This magnificent work has been long and eagerly anticipated, and will be found to realise the fullest estimate of its importance. It consists of one large volume of 1,816 pages, closely printed in double columns, and every article bears the full signature of its author. The list of contributors includes 158 names well known to the profession as those of authorities on the subjects about which they write, and the whole work will long remain an indispensable book of reference to every working practitioner of medicine.

A SUPPLEMENTARY Catalogue of the Pathological Museum of St. George's Hospital has just been issued. It consists of a description of the specimens added to the museum during the years 1866 to 1882, and has been prepared by Dr. Isambard Owen. The book commences with thirty-four pages enumerating the order of specimens in the permanent index number and in the catalogue number of 1866, all of which could have been easily explained in less than half a page, and could have been, therefore, omitted. The rest of the work has been very carefully prepared after recent examinations of the specimens and of the clinical details of the case. The method adopted is a description of the pathological specimens, followed by an instructive abstract of the history, signs, and symptoms of the case during life. The classification is complete, so that reference to the work

would at once show whether any particular case or its varieties were represented in the museum. Such a printed catalogue of all the museums of the London hospitals would be welcome to all who devote time to literature, and would be to them a great saving of both time and labour.

WITH the present number (xxvi.), the first half-yearly volume of Coles' "Studies in Microscopical Science," the new aspirant for fame in microscopical literature, comes to a close. From the first number of the "Studies" to the present nothing short of the most unqualified praise can be bestowed upon them. The editor has thoroughly fulfilled the promises made to his subscribers by furnishing with great punctuality a weekly journal containing an amount of valuable information in histology and microscopical research not to be found elsewhere. The illustrations which adorn the text, and the accompanying mountings, have in no instance failed to sustain their interest and the reputation of the work, that given in the present number being elaborately coloured and forming quite a picture, as well as an interesting study of geological structure. It is a section of Dolerite, cut from a carboniferous rock, central Scotland. The method of preparing all similar specimens is described, and an exhaustive bibliography added. The work as it proceeds will certainly supply the student in microscopical science with a fund of information which he can obtain from no other source.

.*.*

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, October 18th :—Politzer's Text-book of the Diseases of the Ear and adjacent Organs, translated by Dr. Cassells. Quain's Elements of Anatomy, Vols. I, II, edited by Drs. Allen, Thomson, E. A. Schäfer, and G. D. Thane. The Pathology, Diagnosis, and Treatment of Diseases of Women, by Graily Hewitt, M.D., F.R.C.P. Whooping-cough: its Pathology and Treatment, by T. M. Dolan, F.R.C.S. Ed. (Fothergillian Prize Essay). Spinal Curvature, by R. Heather Bigg, C.E. Guide to the Examinations at the Apothecaries' Hall, by W. E. Dawson, L.S.A. Ambulance Lectures, by Lionel A. Weatherly, M.D. Fifteenth thousand. Index Catalogue of the Library of the Surgeon General's Office, United States Army, Vol. III. The Student's Pocket Prescriber, by H. Aubrey Husband, M.B., F.R.C.S.E. The Chamberlens and the Midwifery Forceps, by J. H. Aveling, M.D. A Supplementary Catalogue of the Pathological Museum of St. George's Hospital, by Isambard Owen, M.D. Cerebral Hyperæmia: Does It Exist? by C. F. Buckley, M.D. A Treatise of Diseases of the Liver, by George Harley, M.D., F.R.S. A Dictionary of Medicine, edited by Richard Quain, M.D., F.R.S. The Visiting List for 1883 (Smith and Co.). The Germ Theory of Phthisis Verified, by Wm. Thomson, L.R.C.S.

Literature.

THE TRUTH ABOUT OPIUM. (a)

A VERY large portion of the revenue of our Indian Empire is derived from the sale of Indian-grown opium to the Chinese, by whom it is used for the purpose of smoking; and this traffic has been for the last forty years a subject of keen, and often bitter, controversy between the Anglo-Indians on the one hand, and what may be described as the Exeter Hall Party and the Anti-Opium Society on the other. The Anglo-Indians maintain that without the opium revenue Indian Government cannot be carried along; and they contend, moreover, that opium smoking is much less injurious than the tobacco smoking or dram drinking common in Europe. On the other side, Exeter Hall denounces the Chinese opium traffic as a great national sin; asserts that the opium smoker is a kind of moral *cretin*, lost to all political, social, and domestic ties, and that no considerations of political expediency ought to sanction a Christian nation in continuing it. No end of brochures have been written on both sides, and the present volume may be described as a "brief" on the Anglo-Indian side of the controversy, and is most appropriately the work of a solicitor. We

(a) "The Truth about Opium: being the Substance of Three Lectures delivered in St. James's Hall in February last" By William H. Erereton (late of Hong Kong), Solicitor. London: W. H. Allen, Publisher to the India Office. Medium 8vo, pp. 375.

have read it with interest, and must say that—assuming his facts to be true—the author establishes his case, viz., that opium smoking, if used in moderation, adds considerably to the enjoyment of human life, and is occasionally beneficial. Further, he shows that, as a rule, it is but little abused—certainly to a much less extent than alcohol is in these countries. It appears to us that the anti-opium party have not always drawn the difference between opium smoking and opium eating—a practice of the most baleful character, and which is making a good deal of head in these countries, and still more in the United States. Every physician knows that tobacco chewing is much more injurious than tobacco smoking; and there is the same difference, but in an aggravated degree, between the eating and the smoking of opium, for it is very doubtful whether, in the latter practice, some of the most powerful ingredients of the drug enter the system to any extent. Mr. Brereton mentions one fact which to us appears crucial, and the accuracy or otherwise of which ought to be easily ascertained, viz., that the Chinese Government permit opium to be grown for smoking in such parts of the country as are suitable for it. The cry against opium is principally on moral grounds; but surely it cannot be contended for a moment that a Government is justified in objecting on moral grounds to the import of an article of the alcohol, tobacco, or opium class, if they permit the same article to be manufactured or grown for the same purpose within their own jurisdiction.

There is a very interesting chapter (p. 249) from the pen of Dr. Thudichum on the "Mode of preparing Opium for Smoking, of Smoking it, and of its Effects." Finally, there is the testimony (p. 278) of Dr. Ayres, Colonial Surgeon of Hong Kong, in which, after showing that in prison opium smoking (in a person who had smoked two ounces a day for nineteen years) had been broken off without any injurious effects, he says:—"I am no advocate of opium smoking. My experience is that it may become a habit, but that that habit is not necessarily an increasing one. Nine out of twelve men smoke a certain number of pipes a day, just as a tobacco smoker would, or a beer or wine drinker might drink his two or three glasses a day without desiring more. I think the excessive opium smoker is in a much greater minority than the excessive spirit drinker or tobacco smoker. My experience is that the habit does no physical harm in moderation. In the greatest case—just mentioned—in the jail a better nourished or developed man for his size it would be difficult to see."

It would be difficult to upset the testimony of this eminent and responsible public medical official, particularly as his statements and opinions are amply corroborated by other evidence. One other word: Mr. Brereton states that he applied to the authorities of Exeter Hall for leave to deliver his lectures in that establishment. To make such an application required a certain amount of courage; but it was peremptorily refused. We think that this refusal was not wise on the part of Exeter Hall: had the matter been in our hands we would have granted him the platform free of cost. Q.

Correspondence.

THE CONDITION OF OUR SOLDIERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—There seems to be considerable discrepancy between the public and the private reports on the maintenance and condition of our troops on the field in Egypt and on the voyage home. I do not think there were any complaints respecting their treatment on the voyage out to Egypt in the troop-ships. One would, therefore, be led to suppose that their supplies of food had been more abundant when going out than when coming home. The physical appearance of the troops going out and coming home was very different, the former having been in good condition and robust health, the latter looking gaunt, seedy, and depressed. This great contrast will occur to any one who has been to visit the departures and arrivals of the troop-ships. The condition and health of the horses sent out and returned offers the same striking contrast. Both bodies have evidently suffered from prolonged starvation; and this cast of physiognomy has been well hit off in the illustrated journals.

This ought not to have been brought about in Egypt, as the climate is not tropical, and would be healthy but for

the insanitary conditions of the people and the land. In the accounts of the Indian forces, under Sir D. Baird, in the former campaign of 1801, it is stated that these troops left the country for India in 1802, after ten months' service, in a high state of efficiency and health. They had not, however, been engaged in the battles the British forces fought against the French army, under General Marion; which campaign lasted only six months, including arrival and departure.

This was quick work then, but it has been eclipsed by our present performance of only three months. It will be suggested, therefore, that the energy necessary for the work had now been concentrated into half the time; and that there must have been twice the amount of nervous power consumed in our present campaign than in that one of 1801. It may be hazarded that this nervous energy, if it had been more slowly utilised, would have served for a whole year of ordinary soldiers' duties.

The deduction to be made from this postulate is that the amount of food and rest should correspond with the extra waste of energy, and that the constitutions of the men would really have required to use twice the amount of rations of Abercrombie's force, and four times that required in peace duties. If such increased quantities be not supplied for food to men after unusual action, then collapse of the nervous system will set in, and failure of the heart, which will render the subjects a prey to fevers and dysenteries when camping in infected localities.

The inference, therefore, follows that the soldiers' rations in time of war should be increased to double; whereas, we actually find that they have only had the usual "pound of flesh" served out to them as when in barracks. Even this poor dole of sustenance was frequently denied them under pressure of military exigencies. The preserved meats were issued on the same scale only as the fresh meat; and the former, the men say, never filled them in that quantity, but might if the allowance was increased. Labourers in the open air consume large quantities of food and drink during field work; and these will be found to exceed our barrack rations very much.

Under these inferior conditions of dieting, the starved appearance of our returning troops and horses may be explained, leaving out of account the want of sufficient rest and shelter in the work of campaigning. One would have supposed that the fortnight's rest and dieting on board ship on the voyage home would have reinstated the loss of condition previously acquired. Such has not been the case, however, and the reason may probably lie in the continuance of the inferior dieting the men had been subject to before leaving Egypt.

The soldiers will need, therefore, all the welcome dinners they can get at home to set them up again, which could not probably be done by the ordinary barrack rations in four times the time.

Your obedient servant,

EGYPTUS.

Portsmouth, October, 1882.

MEDICAL ADVERTISING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read your editorial comments on "Medical Advertising" in your last impression with interest, and venture to make one or two observations thereon. You state, "There is no objection, nor has any College a right to object to the extensive advertising of a medical work, so long as that advertising is done for the legitimate purpose of selling the book. Again, to express one's opinion about medical preparations or appliances is reasonable and proper, so long as the opinion is expressed *bona fide*, and for no other purpose save the approval or disapproval of an article of disputed merit." Now, will any reasonable man for a moment doubt that every one found fault with for so doing would maintain that these were precisely the objects and motives under which he acted? Who is to be the judge? It seems to me that this is a question on which every one has to judge for himself, and I thoroughly agree with you that the resolution of the King and Queen's College of Physicians "goes beyond the censorship which the College is entitled to exercise."

As for those who are guilty of the reprehensible conduct on which you animadvert, it is for the public and the profession to distinguish between them and their honest brethren. In the face of so much oblique advertising in the medical pro-

fession, I submit that really too much seems to be made of the fair and open advertising of medical books. It is surely a very venial crime in comparison with the thousand-and-one Protean forms of medical quackery, mainly begotten of the keen struggle for existence, and the scandalous and demoralising excess of charity so subversive of professional integrity and interest. Are the Glasgow "Health Lectures" not huge advertisements? Is there not a vast amount of trash printed in this city of a pseudo-scientific kind, and distributed broadcast to patients? Is the great pecuniary success of the present President of the Royal College of Surgeons not based on a petty half-crown book "On Healthy Skin" extensively advertised in lay papers? As well tell a man that he must wear or not wear a particular garment, as to interfere with his infeasible right of advertising his book for behoof of whom it may concern. It were, in my opinion, an impertinence which no one should brook.

I am, Sir, yours, &c.,

D. CAMPBELL BLACK, M.D.

Glasgow, November 8th, 1882.

THE DIAGNOSIS OF AORTIC ANEURISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whilst thanking Dr. G. F. Duffey for his useful criticism on my report of the case of aortic aneurism opening into the œsophagus, I must express my regret at the somewhat loose phraseology, which, to the inexperienced, would be, perhaps, misleading.

I ought to have said, "with reference to the size and situation of the tumour;" for I am, of course, aware that murmur is not a constant sign of thoracic aneurism. In the words of Sir Thomas Watson, whose clinical clerk I was, at the Middlesex Hospital, about the time of the two pulsating aneurismal tumours referred to in his book, and in which no sound was audible, "a bellows sound is more often absent than present," though it is, he says, frequently present. Roberts Culling, like Watson, from every credible authority, writes:—"Auscultation gives extremely variable results. There may be nothing whatever heard, or only indefinite sounds." Still, I venture to think that, in this particular case, where a large aneurism was situated so near to the surface in the back of the patient, there would, had the ear been applied, have been some auscultatory evidence of its existence, or, failing this, pulsation might have been detected. One of my objects in reporting the case was to point out, more particularly for the benefit of younger practitioners, the importance of taking nothing for granted. I said "probable," and I had good reason for using the word.

Faithfully yours,

CHARLES R. FRANCIS, Surgeon-General.

Clapham Common, Nov. 2, 1882.

NON-REPRESENTATION OF SURGERY ON THE SENATE OF THE ROYAL IRISH UNIVERSITY.

PROBABLY one of the causes for the existing slight to the medical profession is the absence from the Senate of any representative of Surgery. We are far from blaming, or in any way depreciating the capacity of our brethren who have seats on the Senate. On the contrary, we have reason to know that they did their duty to the University and the profession with energy and ability in resisting, without avail, the recent vote, but being short-handed, were defeated. Irrespective of this matter, it is a monstrous state of things that a senate of lawyers and clergymen, tempered with a few pure physicians and Queen's College professors, should have the making of regulations to govern the teaching of surgery and the granting of surgical degrees, respecting which department of education they must be more or less ignorant. It was an item in the miserable bungling of administration which marked the reign of Mr. James Lowther as Chief Secretary that the Senate was framed in utter forgetfulness of this omission, and immediately on its becoming manifest, the Council of the College of Surgeons addressed to the Lord Lieutenant a remonstrance on the subject. That representation elicited a

statement that the propriety of appointing a Surgical Senator would have every consideration on the first occasion that seat became vacant, it being inferred the omission had been inadvertent.

Now the opportunity is afforded to the Lord Lieutenant to redeem his implied pledge. Three vacancies on the Senate exist, one by the death of Dr. Hayden, and two others by the appointment of Dr. Redfern and Rev. Gerald Molloy to Fellowships; and in accordance with the law, one of these offices must be filled by the Lord Lieutenant and two by the Convocation of the University. We confidently hope that Lord Spencer will recognise the anomaly of allowing the Senate to make surgeons without a surgeon amongst them to guide them, and will mend Mr. Lowther's muddle by the appointment which he makes.

THE IRISH ACADEMY OF MEDICINE.

THE Rules of the new Academy having been finally revised and adopted, nothing remains but to elect officers and commence the work of the societies which are co-operating in their new capacity of sections of the Academy. The meeting for election of officers takes place on Saturday next, and circulars have been issued calling on those who desire to become Members or Fellows to send in their subscriptions before that date. Fellows only who have paid will be entitled to vote. The Dublin Obstetrical Society had stood aloof from the movement—at least its Council had—for the members of the Society had, by an enormous majority, declared in favour of amalgamation with the new Academy. However, second thoughts have prevailed, and the Council has, after a meeting held last Saturday, decided to co-operate. Meanwhile, in case any circumstance should intervene to prevent or delay the accomplishment of the scheme, the various societies have met as usual and appointed their councils, so that they may be in a position to carry on their work as separate societies if any hindrance to conjoint action should arise.

PASS LISTS.

University of Glasgow.—The following candidates have passed the respective examinations for the Degrees of M.B. and C.M. of this University:—

FIRST PROFESSIONAL EXAMINATION.

Alexander, A. S.	Hutchinson, T. B.
Alexander, W. M.	Johnston, D. G.
Anderson, J.	Marshall, W. G., M.A.
Bamber, H.	Martin, J.
Bankier, A. M.	Melville, H. B.
Bannerman, G. G.	Mitchell, T.
Baxter, C.	Muir, D. C.
Broom, J.	Muir, W. C. C.
Bryce, A. J.	M'Arthur, J. T.
Buchanan, J.	M'Dermid, J.
Buchanan, W.	Macdonald, J.
Cameron, J. W.	M'Eachern, D.
Campbell, A.	Mackie, J.
Campbell, I. E.	Maclean, J. N.
Campbell, W. D.	Macphail, Digby M.
Christie, W. W.	Macquarrie, J. A.
Countess, J.	Neilson, J. F.
Crowford, R. K. B.	Orr, J. F.
Dodd, J.	Paterson, W. W.
Dunlop, J.	Ralley, J.
Farguherson, J. D.	Ramsay, R.
Ferguson, R. T.	Rankin, W.
Fleming, R. M.	Richmond, A.
Foster, H. S. H.	Robertson, W.
Fulton, A. B.	Routledge, R.
Gibson, J. R.	Rutherford, T.
Gordon, J. B.	Seright, W.
Hallett, C. H.	Smith, J. C. A.
Hamis, Yonup.	Sprott, G.
Hay, W.	Stones, R. W.
Hichen, H.	Wands, J.
Hughes, J.	Whish, C.

Forty-nine candidates were rejected.

SECOND PROFESSIONAL EXAMINATION

Beveridge, Jno.	Macleod, R. L. R.
Birrel, J. R.	Macrae, Alex. M.
Colvin, F. H.	Parker, James.
Cross, David.	Peacock, Alexander.
Cullen, William.	Ritchie, Jno.
Greener, M. H.	Robertson, Alexander.
Hawthorne, O. O.	Rutherford, Hy., M.A.
Blasbewood, Jas., M.A.	Scanlan, Jas.
Jack, Alexander.	Scott, Robert.
Jones, Evan.	Service, R. M.
Kendall, F. K.	Shaw, Jas.
Keogh, Arthur G.	Sinclair, Jno.
Logan, Hugh.	Somerville, Wm. F., M.A.
Miller, Robert A.	Smith, Jas. F.
Montgomery, A. N.	Smith, W. M.
Morris, Geo. A.	Smith, D. M.
Mardoch, J. W. A.	Spence, W. W.
Macartney, Duncan, M.A.	Taylor, Francis.
M'Cracken, Wm.	Temple, Charles D.
M'Creadie, Wm.	Wilson, George.
Macdougall, Alexander.	Wright, Jno.

Twenty-nine candidates were rejected.

THIRD PROFESSIONAL EXAMINATION.

Arthur, D.	Kerr, Jno.
Beveridge, R. E.	Marquis, D.
Blanie, B.	Martin, W.
Brown, W.	Morrison, A.
Brown, W. M.	Macarthur, B. N.
Cameron, J.	Macdonald, J.
Campbell, J. J.	Mackenzie, D.
Crawford, J. C.	Maclean, A.
Dunlop, J. I.	MacNaught, J. B.
Forayth, W. A.	Prangwell, J. T.
Gemmell, J. F.	Prentiss, W. G.
Gibb, W. F.	Quaife, W. F., B.A.
Gourlay, R.	Richard, D. T.
Gray, W. L.	Russell, J.
Hamilton, W. T.	Soga, W. A.
Headrick, J. M.	Stafford, W.
Herbertson, J., M.A.	Steele, R. G.
Hodge, P.	Taylor, W. C.
Hogg, G. M.	Turnbull, E. T.
Howie, A.	Vost, W.
Johnston, A.	Williams, A.
Johnston, F.	

Seventeen candidates were rejected.

Royal University of Ireland.—The following Degrees were conferred on Nov. 8th by his Grace the Duke of Abercorn, Chancellor of the University:—

M.D. DEGREE.

FIRST CLASS HONOURS.—Charles H. Wise.

SECOND CLASS HONOURS.

M'Murray, J. Adams, F. E.

UPPER PASS DIVISION.

Allport, C. W.	Kelly, Michael.
Austin, J. J.	Lindsay, J. A.
Barnes, W. S.	O'Keefe, W.
Bell, T. G.	Prendergast, J. M.
Cromie, Thomas.	Swan, S. A. L.
Heanen, Charles.	White, Daniel.
Jackson, Mark.	

LOWER PASS DIVISION.

Brown, H. R.	Hunter, J. F.
Chambers, A. B.	Legge, R. J.
Cooke, James.	M'Cambridge, J.
Gibson, William.	M'Dermott, Cornelius.
Good, William.	M'Manus, L. S.
Graham, J. S.	Mathews, R. H.
Graham, William.	Moran, John P.
Hamilton, William R.	Moynan, R. M.
Hawthorne, A. W.	Orr, J. Morrison.
Henderson, S. D.	Smith, R. Stafford.
Henry, James.	Wilson, James.

M.B. DEGREE.

UPPER PASS DIVISION.—John Riordan.

M.C.M. DEGREE

Atcock, M. H.	M'Cambridge, J.
Austin, J. J.	M'Connell, T. S.
Barnes, W. S.	M'Dermott, C.
Bell, T. G.	M'Donnell, J. R.
Black, J. G.	M'Manus, L. S.
Chambers, A. B.	M'Murray, J.
Craig, James.	Mathews, R. H.
Cromie, Thomas.	Moran, John P.
Gallway, P. J.	Morell, L. D.
Gibson, W. Walter.	Moynan, R. M.
Haines, H. A.	O'Connell, D. V.
Hamill, Samuel.	O'Keefe, Matthias.
Hamilton, William R.	O'Keefe, William.
Hawthorne, A. W.	Prendergast, J. M.
Heanen, Charles.	Riordan, John.
Henderson, S. D.	Rountree, G. A.
Henry, James.	White, Daniel.
Lindsay, J. Alexander.	Wilson, James.
Lithgow, J. M'G.	Young, J. V.

DIPLOMA IN OBSTETRICS.

Adams, F. E.
Allport, O. W.
Chambers, A. B.
Cromie, Thomas.
Gibson, William.
Hines, H. A.
Lyons, R. W. S.

M'Murray, J.
Maguire, C. J. O'F.
Mathews, R. H.
O'Keefe, William.
Prendergast, J. Moran.
Rountree, G. A.

Royal Colleges of Physicians and Surgeons, Edinburgh.
Double Qualification.—The following gentlemen passed their first professional examination during the October sittings of the Examiners:—

Beaumont, A. Wm., Cambridge.
Aspinall, Samuel, Blackburn.
Clarkson, T. J. R., Yorkshire.
Clarkson, H. G. H., Yorkshire.
Clay, Challoner, Wiltshire.
Pepillon, Thomas A., Berkshire.
Masters, Alfred T., Dorsetshire.
Evans, Wm. G., Cardiganshire.
Huels, E. I., St. Louis, U.S.A.
Anderson, David, Dollar.
Turner, Arthur C., Derbyshire.
Macnab, Joseph, County Cork.
Kean, Thomas, Galway.

Johnson, H. E. G., Liverpool.
Heyworth, T., Lancashire.
Patterson, T., County Donegal.
Nairn, David M., Dundee.
Beattie, James, County Antrim.
Clark, Smollett Samuel, Madras.
Donesan, James, Cork.
Wheeler, R. J. S., Clonakilty, Cork.
Callender, M. R., South Shields.
Martin, Thomas B., Sunderland.
Clark, Duncan, Argyllshire.

And the following gentlemen passed their final examination, and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh, during October and November:—

Ross, Thomas, Southlandshire.
Steel, John, Poonah.
Munday, James, Poonah.
Wood, John C., Sunderland.
Cody, William, Longford.
Culpin, Millies, Buntingford.
Kees, Arthur, Madras.
Waddell, William, Ballymena.
Foggin, J., Newcastle-on-Tyne.
Fryer, Wm. F., County Carlow.
Roberts, Robert G., Liverpool.
O'Callaghan, Jeremiah, Cork.
Scully, Denis, Tipperary.
Tisdall, John J., Mullingar.
Rowe, Edmund Lewis, York.
Huey, David, Ballynaries.
Green, Henry, Manchester.
Preston, Henry H., Manchester.
Holdsworth, William, Whitby.
Fayson, William, Motherwell.
Fraser, Samuel, County Down.
Johns, Wm. S., Wells, Norfolk.
Davies, Daniel Rees, London.
Rogers, Harry C. E., Plymouth.
Powell, John, South Wales.

Williams, R. A. H., Dungarvan.
Wagner, Richard, Poonah.
Douglas, Edwin, Edinburgh.
Harrison, G. C., Nottingham.
Irwin, James R., County Derry.
Mackey, Samuel, Letterbratt.
Silverwood, W. B., Shelly, Huddersfield.
Hamilton, John B., Drogheda.
Storrer, Wm. M., Aberdeenshire.
Watson, A. O. C., Bombay.
Adams, John B., Caermarthen.
Babst, C. T. U., Newcastle.
Cousens, Wm. C., Ottawa.
Malony, M. J., County Tipperary.
Walsh, Edward P., Coolnagour.
Murdoch, Alex. Brown, Elgin.
Bake, C. J., County Galway.
Torrens, J. L., County Derry.
Coady, D. P., County Kildare.
De Watteville, W. F., Berna, Switzerland.
White, John Richard, London.
Gorham, John, Clifden, County Galway.

ing next, at 7.30 o'clock, in the rooms of the Anti-Compulsory Vaccination Association, Victoria Street, to be followed by a discussion, in which friends and opponents of the Acts are invited to join.

F.R.C.S.—We believe the announcement to be quite correct; but honours do not always fall into the lap of merit, nor rewards to those who have a right to expect them. We cannot answer your query—"What has he done to merit it?" but exclaim, What, indeed!

A MEDICAL MAN CHARGED WITH MANSLAUGHTER.—We regret to learn that Mr. Wm. Hawkins, late Assistant Medical Officer to the Gloucester County Asylum, has been charged before the Gloucester magistrates and committed to take his trial on a charge of manslaughter of a patient named Walter Partridge, who died recently in the Asylum from fractured ribs, said to have been caused by the violence of Mr. Hawkins. The prosecution was ordered by the Home Secretary in consequence of the sudden death of Partridge after a bath. He was a dirty, troublesome patient, fifty-three years of age. About two hours before his death the accused bathed deceased and another patient, and it is stated he, along with two keepers, got the deceased down, jumped on his stomach, and made him cry "Murder."

MEETINGS OF THE SOCIETIES.

HARYKIAN SOCIETY OF LONDON.—Thursday, Nov. 16th, at 8.30 p.m., the Report of the Alcohol Committee.—Dr. Francis, "On the Treatment of Neuralgia."

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Friday, Nov. 17th, at 7.30 p.m., Mr. Rogers Field, "On some of the less recognised but important points in the Drainage and Ventilation of Houses."

MEDICAL TEMPERANCE ASSOCIATION.—Wednesday, Nov. 22nd, at the rooms of the Medical Society of London, at 4 p.m., Dr. Richardson, F.R.S., in the chair, paper, "On Inebriety caused by Mental Injuries;" to be followed by a discussion, in which all medical men are at liberty to take part.

Vacancies.

Bradford Fever Hospital.—Resident Medical Superintendent. Salary, £150, with board, &c. Applications to be made to Mr. C. V. Woodcock, Albany Buildings, Bradford, on or before Nov. 21st.
Callan Union, Ballingarry Dispensary.—Medical Officer. Salary, £100, and £20 as Medical Officer of Health. Election, Nov. 22nd.
Cane Hill Asylum, Surrey.—Medical Superintendent. The salary and emoluments will be £700, with unfurnished house, &c. Applications to be addressed to the Clerk to the Committee of Visitors not later than Nov. 20th.

Dundalk Union, Carliford Dispensary.—Medical Officer. Salary, £100, and £25 as Medical Officer of Health. Election, Nov. 25th.
Ennisecorthy Union, Killan Dispensary.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Nov. 21st.
Galway Union, Arran Island Dispensary.—Medical Officer. Salary, £120, and £15 as Medical Officer of Health. Election, Dec. 1st.
Royal College of Surgeons, England.—Examiners in Anatomy and Physiology. Applications to the Secretary on or before Nov. 26th. (See Advt.)

Wolverhampton and Staffordshire General Hospital, Wolverhampton.—House Physician. Salary, £100, with board, &c. Also House Surgeon. Salary, £120, with board, &c. Applications to be addressed to the Chairman of the Medical Committee not later than Dec. 4th.

Appointments.

ASHB, St. G., L.R.C.S.I., Medical Officer for the High Street Dispensary of the South Dublin Union.

BREBENOT, J. L., F.R.C.S.I., L.K.Q.C.P., Resident Medical Officer to the Scarborough Friendly Societies' Medical Association.

FIRTH, E., M.B., C.M. Edin., Medical Officer to the Norwich Dispensary.

JACKSON, J. H., M.B., C.M. Ed., Junior House Surgeon to the Wigam Infirmary.

KEMPE, J. A., M.R.C.S., L.R.C.P. Lond., Senior Demonstrator of Anatomy at University College.

KIDD, P., M.B., M.R.C.P. Lond., Pathologist and Curator to the Hospital for Consumption and Diseases of the Chest, Brompton.

LUCAS, R. C., B.S., F.R.C.S., Surgeon to In-Patients at the Evelina Hospital for Sick Children.

MACLEAN, K., L.R.C.P., L.R.C.S., Honorary Surgeon to the Stockport Infirmary.

MOORE, J. B. G. G., M.R.C.S., Medical Officer for the First District of the Onger Union.

ROBINSON, C. W., M.R.C.S., Medical Officer for the Tynemouth District.

Marriages.

ALLT-NEVE.—Nov. 8th, at St. Botolph's Church, Aldersgate, London, Nathaniel Wm. Allt, L.K.Q.C.P., of Wittersham, Kent, to Catherine Fanny, eldest daughter of T. E. Neve, of Wittersham.

MCNEILL-PITT.—Nov. 2nd, at Cullumpton, Devon, John P. McNeill, B.A., M.D., T.C.D., of Knockmore, co. Antrim, to Louisa, youngest daughter of the late William Pitt, Esq., of Woodcockswell, near Cullumpton.

NASMYTH-DENNY.—Nov. 7th, at Woodlee, Dumbarton, Thomas Goodall Nasmyth, M.B., C.M. Ed., Cowdenbath, Fifeshire, to Violet Nicol, elder daughter of the late Archibald Denny, of Dumbarton.

Deaths.

BOYD.—Nov. 10th, Isabella, wife of Robert Boyd, F.R.C.P., of 1 Bolton Row, Mayfair, and Southall Park, Middlesex.

HENRY.—Nov. 6th, at Stewartstown, Robert Henry, M.D., aged 32.

LATHAM.—Nov. 7th, at Ballymoney, William Thomas Latham, F.R.C.S.I.

SOULEY.—Nov. 4th, very suddenly, from disease of the heart, at Waverley House, Hull, Henry Souley, M.D. St. And.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

DR. CLIPPINGDALE (Kensington).—Your communication is unavoidably held over, the engraver having failed at the last moment to furnish us with the necessary illustration.

DR. BELLA (Paris).—Our Publisher, considering your advertisement of a doubtful character, has handed it to us. In this country it is unusual for any but quacks to advertise the cure of "secret maladies," and we cannot allow the advertisement columns of the *Medical Press* to be made the vehicle of such objectionable announcements.

CETTAGE HOSPITAL.—We have seen the peat-moss used in some of the larger hospitals, both as a styptic in wounds and surgical operations, and also as a deodoriser on dissecting-room floors. In both cases it has answered admirably.

STUDENT (Edinburgh University).—The book referred to is an excellent example of what a class-book should be. You cannot do better.

AN INHABITANT.—The question may now be considered settled by the delivery of judgment by the final court of appeal. What action the Board intend taking is shadowed forth by the following resolution which was passed on Saturday last:—"That having regard to the fact that the judgment of the House of Lords in the Hampstead Hospital case has now been delivered, the General Purposes Committee of the Metropolitan Asylums Board be empowered, in accordance with the recommendation contained in their report of the 28th July, 1881, to institute inquiries with a view of ascertaining whether a site or sites suitable for the erection of one or more convalescent hospitals can be obtained within a reasonable distance of the metropolis."

DR. WILSON.—The appointment is filled up. This, like most of the class, resulted from personal influence.

ANIMAL VACCINATION.—We are requested to announce that Dr. Chas. Jenner will read a paper on "Animal Vaccination" on Monday even-

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 22, 1882.

ON SOME IMPLICATIONS OF DISSOLUTION OF THE NERVOUS SYSTEM. (a)

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P., F.R.S.,
Physician to the London Hospital, and to the National Hospital for the Epileptic and Paralyzed.

(Continued from page 414.)

I HAVE been said not to take note of the "Suppleance" (I use the word Compensation) of one part of the cortex for another. As a matter of fact I have, so far as I know, long ago carried the doctrine of compensation, and that as to all centres, further than any other physician; for example, *Edinburgh Medical Journal*, Oct., 1868. The following, referring to the constitution of the cerebrum (the *Medical Mirror*, Oct., 1869), surely carries that doctrine far enough. The quotation by itself may be taken to imply "universalisation," but before that time I had stated the doctrine I re-state in this paper:—"When in the cerebrum we have arrived at an interrelation so great that each part of that organ contains processes [nervous arrangements] for movements of the whole of the body, we can, as aforesaid, understand that destruction of much of that organ may lead to no symptoms; but if part of the grey matter of the organ be not destroyed, but unstable, it is plain that there must be symptoms by its discharge." The fact is that I then carried the doctrine of compensation further than I now do. The quotation implies absolute compensation, whereas I believe now that there is no such thing. There are many degrees of compensation, from slightest to seemingly complete.

Let us return to the crude symbolisation to illustrate Compensation. One part of what follows may be looked on as an endeavour to show how it is that what we call recovery follows in some cases of paralysis resulting, not from "impairment of function" of part of a motor

centre, but from permanent annihilation of part of it. We of necessity recapitulate, for the doctrine of Compensation is only another aspect of the doctrine of Localisation I have propounded.

If any one of the seven terms be destroyed, there will be some loss of power in the three muscles, X, Y, Z, although on destruction of some one of the terms the loss of power in one or two of the three muscles may be inconspicuous. Really there is loss of a movement in which each muscle serves in a different degree. But X, Y, and Z are still represented in every other term, and thus six other movements, each of all three muscles, remain. Observe, otherwise stating the preceding, the paralysis from loss of any one term is widely distributed, although it may appear to be much more of some one of the three muscles, according to the particular term destroyed. Instead of saying that the "muscular region is weak," or that there is "partial paralysis," we say that one movement of the whole region is absolutely lost, and that six other movements, each of the whole region, remain as perfect as ever; the condition is duplex, negative, and positive. Supposing the first term to be destroyed, there is loss of x^1, y^1, z^1 ; the muscle X appears much weakened, but it remains still represented in other movements by x^{23} ; Y and Z appear to suffer scarcely at all—not appreciably at all—because they remain almost as fully represented in the centre as when it was intact, by the other terms. There is loss only of two P's out of thirty-four, and of but one Z out of twenty-six. The loss of the movement $x^1 y^1 z^1$ is largely compensated in time by greater activity of the six remaining terms. Compensation does not, in this scheme, mean that nervous arrangements take on duties they never had before, but that, having more or less closely similar duties, they serve—not as well, but only—next as well as those destroyed. Plainly, the compensation is in no case of destruction of part of a centre absolute, and in the illustration given it is very imperfect. In many cases we may say that compensation is "practically perfect. An hemiplegic man seems to

(a) ERRATA.—In the last line of footnote (a) in first column of page 418, read "from most to least automatic."

recover perfectly, although some nervous arrangements of his motor centres are annihilated. Prompt recovery in some cases leads to the hypothesis that there is a "functional lesion." I contend that recovery follows when some nervous arrangements are gone, never to be restored. The reader must bear in mind that we speak of cases of apparent recovery in which some nervous arrangements are gone for ever—there is a "hole" where they once were.

When the first term is destroyed there *appears*, we repeat, to be decided paralysis of X only, but slowly the other terms come to serve for moving the whole region more efficiently, and what is called the paralysis of X diminishes. There is *some* compensation. If we suppose there to be destruction of the third term only, there would be rapid compensation. There is from its destruction loss of but five *x's* out of fifty-four, of seven *y's* out of thirty-four, and of four *z's* out of twenty-six.

One of my critics describes my endeavour in an exposition of the hypothesis of Compensation I gave (*Brit. Med. Journ.*, May 10, 1873) to be to show that cerebral centres *do*, and also that they *do not*, represent movements. I simply try to show that when a part of a centre is destroyed, the rest of the centre—the part not destroyed—serves next as well as the part lost, and that in some cases compensation is practically perfect.

We have spoken of destruction of terms; now we speak of abnormal discharges of terms; we have already done so incidentally.

Suppose that the cells of one term become highly unstable, and that they occasionally discharge excessively. Discharge of the first term, $x^{21} y^3 z$, will convulse the whole region, but the muscle X will suffer most spasm—twenty-one times more than Z. The spasm will *appear* to be limited to the muscle X, since Y and Z, being so little represented in the term discharged, will not appreciably suffer.

If we suppose the third term, $y^6 x^7 z^4$, to become highly unstable and to discharge, the whole region will be strongly moved—more strongly than from healthy discharge of the term—in a particular way, and the muscles, X, Y, and Z, will be nearly equally engaged in that movement—the spasm appears to be thin and evenly "spread" throughout the region; popularly the whole region is a "little stiffened," or has slight twitches; the region is but slightly convulsed. Then, to return for a moment, to destruction of terms. If the third term be destroyed, the whole region cannot be moved in a particular way, and the three muscles will exhibit a nearly equal degree of impotence—the paralysis appears to be thin and evenly "spread" throughout the region; popularly the region is a "little weak;" a nomenclature which hides the real thing that a movement of the whole region is lost from annihilation of one term of the centre and that six other movements remain. We now illustrate a further matter—that a negative and a positive lesion may co-exist in a centre.

Suppose the third term to be destroyed; there is for ever a loss of power in moving the *whole* region in one particular way. Suppose next that the fifth term, $x^3 y^4 z^3$, becomes highly unstable; it will occasionally discharge strongly and thus convulse the *whole* region; that is, it will develop a movement, not quite like the one lost but very like it. This illustrates, very artificially, what often occurs, convulsion of the whole of a region, the whole of which is permanently somewhat paralysed. We are here repeating a former illustration with some unessential modifications. We next try to show that there is a far greater difference betwixt the effects of destruction of terms and discharges of terms than has been so far pointed out.

Besides the obvious difference betwixt destruction of a term and excessive discharge of a term, there is another difference. When a term is destroyed the other terms are left intact, are not interfered with; for the local negative lesion is a nothing—a hole. But in the case of excessive discharge of a term it is otherwise. The

highly unstable cells may be likened to a fulminate; by the rapidity of their decomposition they discharge collateral *healthy* terms. More or fewer of the healthy terms, according to the gravity of the initial discharge (that of the term become highly unstable), will be discharged. In other words, the currents from discharge of one term spread in two ways, for besides "downward" lines to the periphery, there are, in centres, "cross" lines—lines of integration. The energy liberated by any term will give rise to "cross" as well as to "downward" currents. (a) Suppose the term $x^{21} y^3 z$ to become highly unstable, the other six remaining healthy. The excessive discharge of this term will produce convulsion of X Y and Z, or rather develop a movement in which X is largely, Y slightly, and Z very slightly, concerned. Next will be added on to the continuing discharge of the first term the secondary discharge of the healthy term $x^{14} y^3 z^3$, so that by this time the discharge will be of $x^{35} y^6 z^3$, and the spasm of X Y and Z will be corresponding. Strictly speaking, two different movements, each of the whole region, are at this stage being developed at once, and are co-operating with and antagonising one another. There is a compound sequence of spasm. We need not illustrate further, as to do so would be essentially repeating the principle stated as to compound order of paralysis. What is said on both is only another way of describing the principle of Compensation, and is in entire harmony with what was said on convulsion of the whole of a region, which is, "paralysed to the will," and with what has been recently said of the case of destruction of the third term with instability of the fifth.

(To be continued.)

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.,
Surgeon to the London Hospital.

I.—SYMPTOMS AND DIAGNOSIS. (b)

THE primary symptoms of rupture of the urinary bladder will be more or less marked, according to the condition of the patient at the time of the occurrence. If the sufferer, as is too frequently the case, happens to be intoxicated, he may be unconscious of anything amiss. He may be found lying insensible on the highway, or be picked up in the street as simply inebriate, and be carried to a police station or to the hospital, or walk into an adjoining room and go to bed, or stagger to his home, and only become alive the next morning, or, after the lapse of several hours, to the fact that he has sustained a grave injury. If the accident occurs to a sober individual, or to one who is only convivial, or slightly tipsy, there will be at the moment of rupture intense pain at the umbilicus or in the hypogastrium, and, perhaps, faintness or complete syncope, and a feeling of something having given way within the abdomen. To quote a few instances, more especially in illustration of the last symptom, in addition to those reported by Scott, Lynn, Garry, Wilmot, Howship and Lloyd adduced in the previous part of this paper. A stout young man of seventeen, who, fortunately, came under Mr. Syme's care, and happily recovered, experienced immediately an intense pain, with a feeling as if the bowels had protruded. His brother remarked that his clothes were distended over his belly. In Mr. Prescott Hewett's collection, a woman thrown down by her husband in a scuffle, and knelt upon with great force, was immediately sensible of having sustained a severe internal injury. A woman in labour, whose case is given

(a) In some cases, as in *le petit mal*, the "cross currents" are chief; the "downward currents" slight; the currents from the primary local discharge in the highest centres can overcome the resistance of many collateral centres of those highest centres—hence complete loss of consciousness—but can only overcome the resistance of small cells of the middle centres. Hence little, but yet widespread, convulsion, or miniature convulsion (described as "shuddering," "slight tremor," &c.).

(b) The first part of this paper appeared in the *Lancet*, June 3, 10, 17, 24, 1882, and an Abstract of this part appeared in the *Lancet* for Oct. 22, 1882.

by Dr. John Ramsbotham, and already referred to, had a sudden pain on the right side of the navel, and a feeling of something giving way. Mr. Collis's patient, a woman, 26 years of age, of intemperate habits, retired to rest without emptying her bladder, and got up for the purpose. Being unsuccessful, she endeavoured to get into bed again, but fell across the footboard. She felt something give way inside her, fainted, and was lifted into bed. Mr. Cusack's first patient, M. G., æt. 26, a servant, who had drunk largely of whisky punch before going to the theatre, feeling a desire to void urine, attempted to leave the gallery of the theatre, and, while doing so, fell and struck his hypogastric region against the edge of one of the benches. He felt as if his heart had burst. His second patient, E. S., an ostler, æt. 30, who fell a height of twenty feet from the battlement of a bridge into a garden, experienced a peculiar feeling about the præcordia, as in the preceding case. Mr. Gamack's patient, an adult male of 21, in good health, caught under a falling bank of earth, felt something give way in the belly. Mr. Willett's patient, a man 48 years of age, called up in the morning to fight another man, and in too great a hurry to give his adversary satisfaction to stay and empty his bladder, which he knew was full, felt, at the moment when he received the fatal kick, that something had given way in his abdomen. Reference to the cases in which the bladder has given way from over-distension, and which I have already quoted, will show that a similar sensation was experienced. Mr. Garry's patient felt something "suddenly jump in his belly," and Sir E. Home's patient, after an urgent desire to make water, felt a rush from the upper part and a severe pain in the region of the bladder, the desire ceasing at once.

In the majority of cases of intra-peritoneal rupture the power of locomotion is either abolished or very greatly impaired. Mr. Cusack's first patient was incapable of raising himself up, or of standing without support, and was compelled to incline his body forward. Montague's patient stood for a few moments and then fainted. Mr. Willett's patient was seized with acute pain, was helped up, and taken into the house. McGuinness, a patient under Mr. Hamilton, of Dublin, (a) was engaged in a fight after a brawl in a public-house; his antagonist fell on him. He got up, complained of great pain, and was carried home. Mr. Wathen's patient, a surgeon, 31 years of age—whose horse had fallen on him after conviviality—helped to undress himself and stood up leaning a little forward. A woman of 28, intoxicated, whose case is reported by Mr. Stokes, (b) was unable to rise after her fall, and was carried upstairs. The following morning, when admitted into Richmond Hospital, she was barely able to walk.

Even if the sufferer be able to walk he will, in all probability, do so slowly, painfully, in a stooping position, or with the assistance of others. Thus, Wm. Sykes, 31 years of age, whose case is reported by Mr. Hiley, (c) received several kicks on the abdomen in a drunken brawl in an ale-house. He was sobered by the accident, and walked home a quarter of a mile in great agony with cries and groans, and he was compelled to walk in a stooping position. J. L. Baker, 29 years of age, under Mr. Bower, (d) fell in a scuffle, and his abdomen came in violent contact with the corner of a table. He was placed on a form, complained bitterly of pain in the abdomen, but, supported by two men, walked home, where he passed a restless night. A few have been able to walk a short distance after the injury, or on the following day. Mr. Poland's patient, John P., æt. 35, stout and well-built, had been drinking, and betook himself to jumping over a stile; he succeeded in doing so, but came violently on a heap of stones on the other side of the stile, striking his abdomen as he fell. Though suffering much, and bleeding from the wound caused by the injury, he

managed to walk some thirty yards to a surgeon who tried to catheterise, but failed. The man passed a little drop of blood instead of urine that night. After thirty-six hours had elapsed he was brought to Guy's Hospital. Mr. Stapleton's (a) patient, Charles Scarlett, 22, labourer, drunk, fell from a ladder, a distance of 12 feet. He was taken to Jervis Street Hospital, Dublin, in a cab, but sent home. The following morning he walked from his lodgings in Britain Street to the Hospital. Dr. McDougall states that a man came to his hospital thirty-six hours after a severe fall, walked into the out-patient room, and from thence to his bed, making all the while little complaint of pain. He died five days afterwards, and his bladder was found to be extensively ruptured, but whether through the peritoneum or not is not mentioned. Anton Graw's (b) patient, a man of 37, thrown to the ground in a fight, and injured by some one falling on his belly, experienced intense pain. The following day he could merely reel without help and drag himself slowly along.

In five cases the power of locomotion seems to have been retained to a more remarkable degree. In his standard work on medical jurisprudence Dr. Alfred Taylor adduces, *but only on the verbal authority of a pupil*, the case of a gentleman who had been compelled to retain his urine, and had his bladder distended. He descended a staircase, fell and struck the lower part of his abdomen against a stair. The sense of fullness of his bladder ceased and he walked to a friend's house to dinner. He recounted the accident to a surgeon present, and the latter at once suspected that the bladder was ruptured. The patient died in 24 hours. Stephen W., a bricklayer, æt. 36, after drinking with his friends at a public-house, was knocked down, while intoxicated, and run over by a cab. He was taken to the house of a surgeon in Lambeth, who dressed a slight wound in his head. After this he walked home to Pimlico, a distance of nearly two miles. Mr. Hird, (c) who reports the case, saw him at 11 o'clock the same evening, about three hours after the accident. He found him in bed, but unable to give any account of his sensations at the time of the accident, as he had drunk to excess.

Dr. Harrison gives an extraordinary case. A man, of 35, intoxicated, was fighting, he was thrown down, and his antagonist fell across the lower part of his belly. He felt excessive pain in the hypogastrium. Sick and weak he rallied and walked home alone, tried to urinate, but could not. He passed a restless night, but had some sleep. He made ineffectual efforts to urinate, took some breakfast, and walked three miles to a surgeon. The catheter was introduced, and drew off six ounces of urine. He walked home again and passed two ounces of urine. On the third day he rose and began his usual labour. At noon he felt so sick that he drank some whisky and walked again to town, three miles, for medical relief. On the fourth day he still kept about and passed urine at frequent intervals, but the symptoms increased in severity. He got worse and gradually sank eight days after the injury. The result of the post-mortem examination is noteworthy. There was an oblique fissure in the bladder an inch and a half in length, and the cavity of the pelvis was separated from that of the abdomen by agglutination of the lower intestines with the bladder. A quart of colourless urine containing shreds of lymph was found in the pelvis. In Dr. Gillespie's case, (d) which is worthy of careful study, remarkable powers of locomotion were shown.

M. M., æt. 31, a tailor, was drinking in a tavern on 29th November, 1858, and had some altercation with another man. A wrestling match ensued which ended in M. M. being thrown, his adversary falling on the top of him. He left the tavern, and shortly afterwards fell backwards upon his nates down a flight of steps. He was very

drunk, but complained of severe pain in the lower part of the belly. He was assisted by the police to the station, where he passed the night, and in the morning he walked fully half a mile to his lodgings. He was suffering much from pain in the abdomen, and was unable to pass any urine. Medical assistance was obtained in the afternoon, and urine to the extent of six or eight ounces, untinged with blood, was drawn off. During this day and the next he was confined to the house with the pain increasing in intensity, and without any further introduction of the catheter. The first night at his lodgings he was in and out of bed, and walking up and down the room, complaining of desire but inability to micturate. On the 2nd of December, at 8 a.m., he walked up to the Infirmary and complained of retention of urine. A catheter was passed, and between five and six pints of clear normal urine were evacuated. He expressed relief and left the hospital. About two hours afterwards he returned complaining of general malaise, his countenance indicating much suffering, and his pulse rapid and thready. He was accordingly admitted as a patient. His skin was moist and cold; there was general uneasiness over the abdomen, most localised at the epigastrium; the pulse was 120 small and thready; the tongue coated at the centre with a dry red margin. In the afternoon the catheter drew off twenty ounces of high-coloured but not bloody urine. Vomiting was almost incessant throughout the day. There was little variation in the symptoms on the two following days, the vomiting, uneasiness, depression, and inability to void urine continuing, and the catheter drawing off urine almost normal in quantity and quality. On December 6th the vomiting had been much relieved by the application of a large mustard blister, but the patient had been excessively restless and slightly delirious, and there were anxiety of countenance and cold perspirations all over the body. On December 7th the patient in a semi-delirious state got up and dressed himself and signified his intention of returning home, and was with difficulty persuaded to return to bed. Before doing so he passed urine voluntarily to the extent of eight ounces. Extreme prostration speedily followed and he died at half-past eight on the morning of December 8th. At the post-mortem the great omentum and visceral layer of the peritoneum presented numerous patches of scarlet vascularity; serous exudation was found in the pelvis with some flakes of lymph. There was no gluing together of the intestinal coils. The bladder was contracted, being a little larger than a hen's egg. There was a vertical rent on the posterior surface an inch in length, proceeding downwards from the urachus. The opening was almost closed in consequence of a protrusion of the mucous and muscular coats. The edges of the wound in the peritoneum were thickened and infiltrated; those of the substance of the bladder presented a decidedly granulating appearance. There was a moderate submucous infiltration of blood.

Another remarkable case is recorded by Mr. Crossley (a) A. O., 24 years of age, received during a fight a blow in the hypogastric region from his antagonist's knee. He experienced a sensation of something having given way, followed by severe pain. These symptoms passing off, he walked two miles to his home, which he reached without difficulty. He tried to pass water but failed. He sent for his medical attendant, Mr. Robinson, who introduced a full-sized gum-elastic catheter, and drew off twenty ounces of bloody urine. This was repeated twice daily up to the day of his admission to the Leicester Infirmary, November 20th, 1871. The patient walked without assistance from the Infirmary door to his bed. His countenance was rather anxious; his pulse 80; his skin cold. There was a sensation of weight in the hypogastric region, but no tenderness on pressure. On percussion the area of dullness over the abdomen was increased, and there was a distinct sense of fluctuation on palpation. A silver catheter was immediately introduced, the abdominal dullness and fluctuation entirely disappearing. A gum-elastic catheter was passed night and morning. He went on well till the evening

of December 1st, when, without premonitory symptoms, he was attacked with convulsions, rapidly followed by coma. Every effort was made to rouse him. A catheter was immediately introduced, and about twenty ounces of urine were drawn off, consciousness returning in about an hour. On the following day he was again attacked in a similar way, and on December 3rd he was seized with a more violent form of convulsions, and sank in three hours into a comatose state which ended in death. An oblique laceration two inches in length was found on the posterior surface of the bladder.

(To be continued.)

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

I.—ANATOMICAL CONSIDERATIONS.

THE anatomy of the hip-joint presents many details of surgical interest, the principal of which are as follows:—

The floor of the acetabulum is the weakest part of the innominate bone. In the dry specimen it is generally thin enough to be translucent. In the natural state it is protected from injurious pressure by the Haversian gland—a mass of fat and blood vessels; and when this succumbs to the action of disease, which it does readily, there is no periosteum to protect the bone beneath; hence the frequency of perforation.

The inner side of the pelvic wall deserves attention, as it indicates the direction pus may take after passing through a perforation in the acetabulum. In Fig. 1 the circumference of the acetabulum is represented by a circle; the attachment of the obturator internus muscle by a dotted line. It is obvious that a perforation of the acetabulum must open internally in one of three positions: it must open either into the obturator muscle, in front of it, or behind it. If it opens into the muscle, then pus will pass through its substance and emerge with it at the small sciatic notch (in the direction of arrow A), and point upon the natis. If, however, perforation takes place behind the obturator, then matter will pass into the ischio-rectal fossa, and may open either upon the perineum or into the rectum (arrow B). In most cases, however, perforation takes place anterior to the origin of the muscle, and then the matter passes upwards (arrow C) in the sheath of the obturator vessels, and points in the groin.

It may be noticed that the matter is well shut out from the peritoneal cavity, perforation of which has never been known to occur consequent upon hip disease; for beneath the peritoneum is the strong and elastic pelvic fascia, which forms an efficient protection. This fascia, however, does not pass above the ilio-pectineal line; and if pus should find its way into the iliac fossa, it would come into contact with the uncovered surface of the colon, and into the bowel at this point it has been known to pass.

The extent of articular surface exposed to disease is larger than may be supposed. The circumference of the articular portion of the head of the femur averages six and a-quarter inches in the adult, and, assuming the head to be two-thirds of a true sphere, then the articulating area will be about nine and a-half square inches. With similar measurements for the acetabulum, it may be inferred that about twenty square inches of bone and synovial membrane are exposed to disease in a case of inflammation of this joint. (a)

The neck of the femur in structure is cancellous, devoid of medullary canal, and invested by a layer of compact tissue. This dense layer is thick below and thin above; hence we find that caries travels more quickly upon the upper than upon the lower surface of

(a) *Medical Times and Gazette*, 1872.

(a) For this estimate I am indebted to my friend, Mr. Arthur Ellis B.A. of Worcester College Oxford.

the neck. In young subjects, however, before the dense tissue is fully formed, disease encroaches with equal facility upon both surfaces.

The round ligament is supplied by nourishment by vessels which enter it both by its pelvic and femoral ends; its nutrition, therefore, is weakest in the centre. Hence we find that when an inflammatory exudation constricts the vessels at either end, the ligament yields in the centre, being in some cases perforated, in others thinned, and in others ruptured.

Development.—It is important to remember that all diseases of, or operations upon, the hip-joint during the first year of life affect cartilage only; from the first to the eighteenth year young, soft, growing bone in increasing proportion; and after this period, well-formed bone.

Nervous supply.—The hip-joint is not supplied by a single nerve whose function is solely the nerve-supply of the articulation. Accordingly, we find *reflected sensations* are common, and pain is felt in the thigh, knee, leg, ankle, penis, and elsewhere in disease of the articulation.

MILK POLLUTION AND DISEASE.

By JOHN DOUGALL, M.D., M.B., F.F.P.S., Glasg.,
Physician to, and Lecturer on Materia Medica, Glasgow Royal Infirmary.

THE lecturer having selected "Milk Pollution and the Spread of Disease" as the subject for the opening address at the eighty-first annual meeting of the Glasgow Philosophical Society, began by referring to a communication on the dissemination of zymotic diseases by milk, which he read to the sanitary section of the society about ten years ago, when strong suspicion was culminating in fact that milk was a vehicle of specific infection. At that period several medical men had either clearly traced or strongly suspected impure milk to have caused numerous cases of typhoid, scarlatina, cholera, and small-pox. Still, a considerable number were sceptical about the matter, while many actually refused to believe it. It was in consequence of this diversity of opinion that he set about collecting the facts of alleged cases of milk-poisoning, and of examining the chemical constitution of milk with special reference to its forming a favourable *nidus* for the reception and dissemination of zymotic poison. The results of his investigations clearly showed that sweet milk was a congenial soil for the preservation and probably even the multiplication of infectious viruses. Since that time the views he then enunciated had had many sad witnesses to their truth in the shape of a great number

of epidemics, chiefly of typhoid, throughout Britain, due to the distribution and swallowing of poisoned milk. The serious character and frequency of these outbreaks latterly obtained for Local Authorities power to control their milk supplies, so that milk-retailers in many towns were now placed under certain restrictions to prevent contamination of the milk. Dr. Dougall then described the chemical composition of milk, showing how perfectly it was adapted for building up all the tissues of the body. The changes which ensued in milk were noticed, and he observed that it was obviously to prevent these changes that milk was intended by nature to pass at once from the milk gland of the mother into the stomach of her young. Such changes were hastened in milk by its being jumbled about in carts and railways, and being exposed to the air by remaining on sale and frequently transferred to different vessels. He also remarked that the large percentage of water in pure milk rendered it very prone to absorb gases and vapours of an offensive nature. Dr. Dougall then related his experiments, which consisted in exposing uniform portions of milk in a glass jar to the emanations of coal gas, paraffin-oil, turpentine, onions, tobacco smoke, sulphuretted hydrogen, ammonia, sulphide of ammonium, musk, assafoetida, stale urine, creosote, stale cheese, chloroform, putrid fish, camphor, decayed cabbage, &c. In every instance he found the milk had become more or less impregnated with the characteristic odours of these bodies. After stating his strong conviction that milk absorbed and could communicate infection, the lecturer referred to the belief of some germ theorists, who hold that the alleged germs of infection withstand a temperature of 212 Fah., and yet they recommend the boiling of milk to render it non-infective by destroying such germs. It had always far exceeded the utmost boundary of his conception to fancy that a temperature which utterly destroys every form of tangible ovum, and every kind of visible seed known, would be resisted by ultra-microscopical organisms. He would accept this statement as true when he was shown a hen hatching a chick from a hard-boiled egg, or a boiled potato sprouting. It followed as a corollary to his view that he believed the boiling of milk destroyed every organism and germ which it contained; and not only so, but he was certain also all infective putrid particles, which he still believed was the form assumed by zymotic poisons. Specimens of milk sugar and sealed capillary tubes filled with milk directly from the cow's teat were shown to illustrate some of his remarks.

Clinical Records.

ST. MARY'S HOSPITAL.

Apparent Cystitis—Renal Cysts and Calculus—Death.

Under the care of Mr. A. T. NORTON, F.R.C.S.
(From Notes by Mr. ARTHUR W. ROWE.)

PATIENT had been twice married, and had had five children, the last being a miscarriage, from which time the mischief seemed to date. Between two and three years ago had a miscarriage. Previously she had had bad health for a few weeks, principally owing to bronchitis. From this miscarriage she made a slow and painful recovery. Five or six months ago she had some little trouble with her water. Her water was like jelly, and offensive. Then followed a little pain in passing water, and slight incontinence. Three months ago the pain increased exceedingly. Catamenia absent for two years. The incontinence had become extreme during the last three months. She had had leucorrhoea for the last seven years, and this had much increased since her miscarriage.

Present Condition.—On admission the patient had piles. When she passed water voluntarily it gave her great pain. She had constant pain over the bladder, and also in the loins. She said that lately she had had no appetite, and but little sleep, and that she had lost flesh considerably. She coughed a great deal. She had never noticed any gravel in her urine. Urine—weakly alkaline, abundant

phosphates, 1020, epithelium, no casts, mucus and pus, and one-fourth albumen.

February 8th.—Was ordered diet simple. Milk, Oj.; beef tea, Oj.; pot. bicarb., gr. xx.; inf. buchu, ʒj.; t. d. s. Fomentations when necessary. 11 p.m. Pot. bromidi, gr. xx.; chloral hydrat., gr. x.; aq. ad ʒj.

On February 9th there was considerable abdominal pain; by no means confined to the region of the bladder. Pain also in back. Pain of a cutting and scalding character. Pulse 80, regular, of rather poor force.

12th.—Fomentation to perineum.

On the 13th the bladder was washed out with quinine twice a day. Pain had been severe in last thirty-six hours, especially that afternoon. Felt very low. Held the last injection for half-an-hour. Had hot fomentations over bladder.

15th.—Was very weak, but pain not quite so bad. Pulse 64, small, hard, and regular. Bowels not open. Port, ʒvj.

16th.—Pain principally over right kidney. She felt rather better on this morning. The urine slightly alkaline and very offensive, and swarming with forms of bacteroids. The amount of sediment varied greatly. On morning of 15th there was one-third of an inch; this morning a good half was sediment—almost all pus—and this afternoon about three-quarters of an inch was sediment.

18th.—Brandy, ʒiv.

19th.—Patient is very low to-day, and complained of great weakness. Pulse 89, regular, small, and weak. Towards evening she became much weaker, and her friends were sent for. She was then almost pulseless. At about 10 p.m. she died.

A post-mortem examination was refused, but subsequently permission was obtained to examine the kidneys, to be removed by loin incisions. There was very little kidney structure left on either side. The left was contracted after rupture of numerous cysts. The right was almost destroyed by cysts; its pelvis contained a calculus, and was the origin of the pus contained in the urine.

The chief important point to be noticed in the case is that the symptoms have been mostly referred to the bladder, though it is probable that the disease first commenced in the kidneys, both of which were nearly destroyed; and the case is an example of the necessity of considering and of ascertaining the exact state of the kidneys in all bladder affections, the difficulty of which is often very great, owing to the symptoms and signs of the renal disease being masked by those of the bladder affection.

Special.

ANTISEPTIC TREATMENT OF TYPHOID.

At a recent meeting of the Academy of Medicine, M. Vulpian read a paper on the result of several experiments made in L'Hôtel Dieu by him on the treatment of typhoid fever. It will be remembered that last year when he read portions of a work by M. Hallopeau, on the curing of this disease by sulphate of quinine, calomel, or salicylate of soda, he remarked that it would be a very interesting experiment to introduce into the digestive tube of the patient substances calculated to destroy the morbid fermentation from which this disease is thought to originate, and that one could, by this means, if not altogether stop its development, at least moderate its intensity and decrease the time of its duration.

M. Vulpian has since tried the effects of iodoform, salicylate of bismuth, boric acid, phenate of soda, and salicylic acid. Iodoform was found to have absolutely no effect on the sufferer from typhoid fever; this is perhaps owing to its being a substance which is but little antiseptic. M. Vulpian then tried salicylate of bismuth. This substance is usually very badly defined; there exists in it liberated salicylic acid, and perhaps also bismuth. It is scarcely soluble and very antiseptic. Mixed with liquids obtained by putrid maceration, it renders them perfectly clear and limpid, kills the ani-

malcules of fermentation which they contain, and takes from them the unpleasant odour which they generally have.

The results of the use of salicylate of bismuth in doses of 10 to 12 grammes daily were not very satisfactory. The disease was not stayed in any particular, but M. Vulpian observed that there was a considerable lowering of the temperature of the patient. The cells were completely disinfected, and there was a general amelioration of the condition; but as against these advantages there are certain disadvantages which compelled M. Vulpian to discontinue the use of this remedy. These are, firstly, an excessive dyspnoea, which appeared two, three, four, or even five days after the administration of salicylate of bismuth; and secondly, nasal and intestinal hæmorrhage outside the proper influence of the disease. M. Vulpian, however, still believes that this remedy may be useful in a certain way for curing or relieving typhoid fever. He then tried boric acid, which is an excellent antiseptic, and harmless to the patient. He gave it in doses of 12 grammes per day in one litre of lemonade. The results were, however, *nil*, neither lowering the temperature nor amelioration of the general condition. Phenate of soda in doses of 9 grammes per day proved harmless also, but its results did not influence so much the local as the general condition. M. Vulpian has therefore arrived at the conclusion that it is not possible to relieve typhoid fever through the intestines, the extraction from them of the morbid fermentation being quite useless. It is probable that typhoid fever results from an intoxication of the blood, as in small-pox, scarlatina, and measles; therefore the septic matter may be got rid of, but it will not prevent the disease developing in the usual way. M. Vulpian hoped to do away with the effects of the poison in the system itself and to improve the condition of the blood after the absorption of the poison, but he admits that as yet he has not succeeded. After the experiment with phenate of soda he tried salicylic acid in doses of 6 to 7 grammes per day, mixed sometimes with phosphate of lime, sometimes with sugar of milk, given in doses of 25 to 30 centigrammes every second hour. He found it quite harmless except with young people who showed a tendency to cerebral salicylic delirium of a particular kind, which M. Vulpian attributed to the action of salicylic acid, as when the latter was discontinued the former ceased entirely. Thus has he proved that salicylic acid, like salicylate of bismuth, produces neither dyspnoea nor nasal nor intestinal hæmorrhage, but what most attracted M. Vulpian's attention, a lowering of the temperature in 48 hours from 40·5 to 37·5 Cent. A similar temperature was obtained by the use of phenic acid, but it only lasted for a short time, whereas in the use of salicylic acid the result lasted as long as the medicine was continued. In other ways the results were also remarkable: there was less prostration and agitation at night, and salicylic acid had a very soothing effect. These results were produced more in light cases than in the more serious ones, but in no case was the duration of this disease shortened. To prove the influence of this treatment on the mortality in typhoid fever a much greater experience would be necessary than the 20 cases examined by M. Vulpian; but the fact remains that salicylic acid ought to be considered one of the most potent remedies for typhoid fever that have up to the present ever been discovered, and far superior to sulphate of quinine, boric acid, phenate of soda, &c. M. Vulpian, in conclusion, declared that, without actually curing typhoid fever, salicylic acid was one of the most powerful remedies yet used for this disease, and asked whether it could not be used as a prophylactic means in epidemics of this nature, and also whether the daily ingestion of this medicine would not annihilate the poison of typhoid. The experiments made in

England on healthy persons prove that salicylic acid can be taken without inconvenience in doses of 2 grammes per day.

M. Roger asked M. Vulpian how he administered the acid, and the latter replied that he gave it in the form of a powder mixed with disinfected bread, and immediately after it some broth or wine. In some cases there was a difficulty in taking it, but with the majority of persons this did not occur.

France

[FROM OUR SPECIAL CORRESPONDENT.]

UNHEALTHY CONDITIONS OF THE DWELLINGS OF THE POOR.—At the last meeting of the Académie de Médecine, M. Marjolin drew the attention of the members to the unhealthy conditions of the poor in Paris, and considered that the spread of the epidemic now reigning was in a great measure due to overcrowding and insufficient drainage. Where six or eight persons were huddled together in one room as is often the case, isolation of the patient as well as proper ventilation and disinfection is impossible. M. Marjolin would wish to draw the attention of the Government to the law relating to the insalubrious habitations which in his opinion was more a dead letter than anything else. M. Lagneau regretted that the law in question was not applied, especially as immigration into the city has considerably increased. Other members took part in the discussion, and having expressed their opinions, which coincided with that of the first speaker, the meeting separated. The President of the Hygienic Council addressed a letter to the Prefect of Police inviting him to aid, in his official capacity, the researches to be made as to the cause of the epidemic; thereupon the Prefect sent round a circular to the mayors of the different arrondissements inviting their co-operation, so that soon we shall have a complete account of the origin and all that has favoured the extension of the fever.

POSSIBILITY OF PERFORATION OF ARTERIES.—At the Société de Chirurgie, M. Monod reminded his colleagues that at the last meeting the possibility of perforation of arteries in purulent collections was contested. Since then he had examined the subject, and he came to the conclusion that not only was it possible, but that many examples were to be found where the artery was perforated spontaneously, especially in the case of chronic or cold abscess or those of osseous origin.

A HIGHER GRADE IN MEDICINE.—The Minister of Public Instruction has addressed a letter to the Rector of the Academy of Medicine, proposing to him the creation of a higher grade in medicine, which should bear the title of "Doctor of Medical Sciences," *Docteur en Sciences Médicales*.

CHLORAL IN CHILDREN'S CONVULSIONS.—Dr. Bouchut, of the Hôpital des Enfants Malades, orders, in the convulsions of children, chloral in rather large doses. This medicament according to him is of the most important necessity in the treatment of all nervous affections in the young, he does not fear to give as much as twenty grains in one dose to a child under a year old. In the above affection, he orders a draught of hydrate of chloral 20, 40, or 50 grains, according to the age, in syrup; the dose of 50 grains is reserved for children of ten years old; or a suppository of chloral thus composed: spermaceti 50 grains, cacao butter 30 grains, hydrate of chloral 20 to 50 grains. The oxide of zinc he considers very useful, and gives it with sugar, oxide of zinc 10 grains, sugar 10 grains, for four powders, two or more to be taken in the

twenty-four hours. Where the convulsions are dependent on the presence of worms, he orders (for lumbricoides), senega contra 10 grains, Corsican moss 10 grains, calomel 2 grains, sugar 30 grains, for four powders, to be given in the twenty-four hours. If the parasites belong to the class of thread worms, he gives a suppository of mercury ointment 1 or 2 grains, incorporated with cacao butter.

Department of Lunacy.

THE ROYAL EDINBURGH ASYLUM.

THE Royal Edinburgh Asylum, we gather from its annual report, continues to prosper under the energetic superintendence of Dr. Clouston, but if its managers wish to attract private patients to it, we should recommend them to omit from their future reports the frontispiece which graces the one just issued—a wood-cut representing Craig House, a branch establishment recently added to the resources of the Asylum. Craig House, if this drawing does it no injustice, must be a lugubrious residence. It is an ancient building in deep shade, and recalls a haunted manor or moated grange, rather than a sanatorium for cases of mental disease. Dr. Clouston's idea of the proper composition of the institution over which he presides is that it should contain 800 patients—400 of the pauper class, 250 lower middle-class patients, and 150 private patients of affluent means. This may be very well for the Royal Edinburgh Asylum, circumstanced as it is, but if Dr. Clouston advances this computation as being not merely suitable to Morningside, but to asylums generally, he will not carry his English brethren along with him. Compound asylums, such as exist in Scotland, in which private and pauper patients are associated either under the same roof or the same administration, have never found favour on this side of the Tweed.

THE WILTS COUNTY ASYLUM.

DR. IRELAND BOWES, the recently appointed Medical Superintendent of the Wilts County Asylum, at Devizes, has issued a very practical and satisfactory report on the condition of the institution under his charge. He makes the curious observation that three cases of typhoid fever, all of mild type, occurred last year in patients resident in different parts of the Asylum, and who had been inmates of it a considerable time. They all made good recoveries, and one, whose mental condition was previously considered comparatively hopeless, has since recovered and returned to her friends, affording, therefore, another instance of what may be called the clearing-up influence of acute febrile diseases, and especially of the exanthemata, in cases of chronic mental derangement of very unpromising type. No definite cause could be discovered for the outbreak of typhoid fever, but Dr. Bowes mentions incidentally that diarrhoea and erysipelas have been prevalent in the Asylum in former years. It is more than probable, therefore, that some grave sanitary defects exist, and a searching inquiry should therefore be at once instituted into the state of the drains and quality of the water and milk supply. If this be neglected we shall expect to hear in future reports of the occurrence of other cases of avoidable disease. Dr. Bowes supplies an unusually full account of the causes of death in the patients who died during 1881, adding to the statement of the primary cause of death in each case a summary of the principal lesions found on post-mortem examination.

FEMALE EDUCATION IN RELATION TO ITS MENTAL AND PHYSICAL RESULTS.

At the Edinburgh Philosophical Institution last week, Dr. T. S. Clouston, Physician Superintendent to the Edinburgh Royal Asylum, delivered the first of two lectures on this subject before a very large audience. There were a good many reasons, the lecturer said, why physicians and physiologists should have opinions about the education of youth rather different from those held by the professional educators; and he proceeded to show that the former viewed the human being as a unit, with the body and mind inseparable, and that the practical aims of modern medicine, founded on this enlarged study of man, were getting more to be concentrated on measures for the prevention of diseases, rather than on measures merely for their cure after they had arisen. Now, to prevent disease one must control the conditions of life, especially in youth, when the human being is most amenable to influences for good and evil that affect the whole future life. The process and the method of education most undoubtedly influenced health very strongly. Vital energy, which was available for many purposes, should not be appropriated for one; and if in a girl they applied to education the energy which ought to go towards growth, and towards the strengthening of the body, they would produce a small and unhealthy specimen of humanity. At the different periods of life nature used her energy in different ways. In babyhood it was chiefly in body growth; in girlhood, partly growth and partly brain development; while in adolescence Nature's effort was to attain a full development of the various functions. The period of adolescence was not one of production, but of acquisition, and they had to see that it was acquisition all round, and not in one single direction only. If the original constitution derived from ancestry has been good, if the conditions in childhood have been favourable, if education has been right, and the development of the whole being in all her faculties equal and harmonious after Nature's plan, then they must have a woman in perfect health, which meant happiness, with the full capacity for work, for resisting evil influences, and for living her allotted time. In pointing out that one might use up by undue pressure at one time of life the power that ought to have been spread over a much longer period, he remarked that the physician must look at the human being from the cradle to the grave, and not one portion only, as unfortunately, the educationist must necessarily do, having nothing to do with life after the period of education was over. He (Dr. Clouston) would have the educator's reputation partly to depend, not on what he turned out at eighteen but on the result at forty, fifty, or sixty. If it had helped life to be healthy, happy, successful, and long, then education had been good; if unnecessary disease, unhappiness, unhealth at any period of life had been the result, then it had been bad. One generation, he submitted, might by living at high pressure exhaust its share of energies, and might thus draw a bill on posterity without transmitting to the next generation enough to pay it. He believed many of them were now having the benefit of the calm, unexciting, lazy lives of our forefathers of last generation. Proceeding to speak of some of the bad results which he thought were caused by the present system of the education of young women, he referred to the physical and mental changes which accompanied the transformation from girlhood to womanhood, and strongly urged the importance of the whole brain and the whole body coming to maturity, pointing out that the developing process stopped at adolescence. Whatever was done then, or left undone, was final. Who

in his senses, he asked, would deny that it was far better for nineteen women out of twenty to begin life healthy than well educated? Alluding to the danger of developing hereditary nervous diseases, he asked, why should they spoil a good mother by making her an ordinary grammarian? It had been said that most great men had had mothers with strong minds, but he believed that few of them had highly-educated mothers. There was usually an innate force and good development of mind and body in the mothers of such men, and they had usually led quiet, uneventful, and unexciting lives. One great argument for higher education was that it made woman a fitter companion for highly-educated men; but he held this view to be erroneous; and, in conclusion, illustrated his contention by pointing to the ideal pictures of young women drawn by Tennyson, Shakespeare, George Eliot, and Thackeray.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 14TH.

JOHN MARSHALL, F.R.C.S., F.R.S., President, in the chair.

DR. JOHN HARLEY read a paper (for Dr. Vasy Lyle, of Durban, since deceased) on

THE ENDEMIC HEMATURIA OF THE SOUTH-EAST COAST OF AFRICA.

This paper discussed the physical characters of the infested country, and the extent of the country infested. In it the author stated, as an almost completely proven fact, that the Bilharzia hæmatobia infested the whole eastern littoral of Africa, from Egypt to the Cape; and that the entozoon found amongst the people of the Nile valley was identical with that found in South Africa. It appeared to inhabit the sluggish parts of rivers and low marshy lands, and to be absent from high lands; the interior plateau of South Africa being free from the disease. The present immunity of Port Elizabeth was attributed to the substitution of rain-water stored in tanks for that of wells and pits. Opportunities were obtained of examining the bladder in a case of the disease, and both the male and the female parasite. The bladder in one case was healthy near the neck, but was crossed thence diagonally to the fundus by fungous-looking growths, and the mucous membrane over these was granular and ulcerated, and contained embedded ova. Referring to the symptoms and progress of the disease, the author remarked that no symptoms of the affection had been observed antecedent to the appearance of the hæmaturia, the general course of the disease being that described by Dr. Harley, in his communication to the Royal Medical and Chirurgical Society some years since. The portion of urine first passed was clear, but the last few drops contained blood, being expelled by the muscular action of the bladder. The presence of the Bilharzia usually caused little distress; only some lumbar or perineal pain in a few cases. Long after the cessation of the hæmaturia, the eggs of the parasite remained. In some cases, the discharge of blood was so great as to cause the urethra to become blocked by clots; and occasionally vesical catarrh was produced. He had never met with a case in which death could be traced directly to the presence of Bilharzia; it was, however, uncertain what influence it might have in the production of inflammation of the liver. In cases of long standing, nephritic colic was liable to occur; perhaps from the impaction of a clot of blood in the ureter, but more often from renal calculus of phosphatic nature. He had not been able to arrive at any satisfactory explanation of the cause of the affection. Griesinger had attributed it to the use of fish, bread, and fruit; but was not supported by facts. Its cause probably lay in the water used for domestic purposes. With regard to the supposed relation of the endemic hæmaturia to the Natal sore, he believed the latter to be an expression of general debility, but not to be connected with the

hæmaturia. New comers were much more liable to the Natal sore than the old residents; and he did not think that the two diseases co-existed in the same person. He had not met with hæmaturia from Bilharzia among residents in Durban; but it was not rare in the rural districts of the infected regions where impure water was used. European females above puberty were not liable to it; but it occurred among European males, especially hunters and overseers of labour, who often used impure water. The Bilharzia affected the ox, sheep, and other animals as well as man; in those animals, it differed in size from that of man, and the ova were cylindriciform at both ends. In 1851, the parasite was discovered in Cairo by Bilherz, who at first called it distoma; it had, however, been thought better to give it a name derived from that of its discoverer. In 1864, Dr. John Harley made an interesting series of observations on its clinical importance. It had since been found in India; and was extending in Egypt. Some of the patients had resided near the so-called "Sweet Water Canal," and had been attacked a few days after drinking the water. As regarded treatment, three methods had been proposed; the heroic plan, the do-nothing plan, and the rational plan. Under the heroic system, medicated injections into the bladder had been carried out to an extreme degree. One author had recommended the injection of two drachms of a saturated solution of alcohol; this set up violent cystitis, and caused the patient great agony for twenty-four hours or even more. It had been concluded, because the patients did not return after this treatment that it was successful; but a patient who had been subjected to it told Dr. Cobbold that he would rather endure the most severe torment than have it repeated. The do-nothing plan was based on the supposition that the patients would outgrow the disease. In 1870, he had under his care a patient aged 6 years, who was passing myriads of ova, and apparently bleeding to death. Under the use of iron, with a nourishing diet of milk, cream, eggs, etc., the fatal result was averted. He would, in cases of endemic hæmaturia, recommend supporting the system by nutritious food, and by the administration of iron and quinine. Buchu was also most valuable in soothing the irritation of the bladder. In severe cases, it would be worth while to try strong parasitocides. In some recent experiments on the larvæ of the Bilharzia, he had found that they were instantly destroyed on coming into contact with a very dilute solution of corrosive sublimate; one part in 10,000 had a decided effect. He did not agree with Dr. Sonsino in thinking that any bad results would follow this treatment.

Dr. RADOLIFFE CROKER referred to the case of a boy, æt. 12, who, at the beginning of the year, passed much blood with his urine, but now scarcely any; a few ova, however, were still voided. The boy was born in the Orange Free State, and contracted the disease in Natal. Specimens of the ova were exhibited.

Dr. JOHN HARLEY, in reply, said that what they had to deal with was one or two nematode worms in the mucous membrane of the bladder, or in the prostate gland, or at the sides of the urethra. As to the mode of introduction of the Bilharzia, various suggestions had been made, but it most probably entered by the urethra during the act of bathing. It was rare among females, but was common amongst school-boys. The natives of South Africa prevent its ingress by tying a piece of tape round the penis while bathing. The affection in Natal was mostly confined to the pelvic organs, while, in Egypt, the parasite was no doubt taken in with the drinking water, and affected the blood generally. He had early advocated injection of the bladder, and had found that, when properly carried out, it not only relieved but cured the patient. In the *Medico-Chirurgical Transactions*, he had described the case of a colonist in Natal who had the disease in a severe form. Solution of iodide of potassium was injected once or twice a week, and, at intervals, male fern. Both these medicines were well tolerated by the bladder. Whether iodide of potassium killed Bilharzia he did not know, but a weak solution killed a leech. The oil of male fern, injected in doses of about a drachm, in barley-water, was retained three or four hours; it was then expelled with an abundance of *débris*. The patient above mentioned, under this treatment, was cured of his malady; and he had remained hearty and active since 1870. Even after the disappearance of the hæmaturia, the patient might still carry the parasite. Dr. Harley referred to the case of two sons of a medical man who had suffered from hæmaturia. Both were apparently in good health, but in the urine he found ova. He afterwards had to attend them for

nephritic colic. He expressed his great satisfaction with Dr. Lyle's paper, which he had the honour of bringing before the Society. The author was apparently the only medical man who had undertaken the investigation of the disease in South Africa.

THE LIFE-HISTORY OF THE LIVER-FLUKE IN SHEEP.

Mr. A. P. THOMAS, of Oxford, exhibited and explained drawings and preparations illustrating the life-history of the liver-fluke, and the mode of its introduction into the bodies of sheep. This parasite caused a great loss among flocks, amounting in 1879 and 1880, it had been calculated, to three millions. Sheep were especially liable to it, especially those fed on low-lying grounds; but, though experiments had been made, especially by Leuckart, to discover its source, none had succeeded. In 1879, the Royal Agricultural Society offered a grant of money for the prosecution of researches on the subject. It was suggested that the late Dr. Rolleston should make the investigation: he, however, could not do so; and it was, therefore, entrusted to Mr. Thomas. He began to work in two directions; he tried to find whether there was an intermediate host, and, if so, what it was. He had made infection experiments on all the common molluscs, and on some small crustacea. He visited every field near Oxford where the parasite had been found, and examined the fauna very carefully, but could not for some time obtain a clue to the history of the fluke. He found in a field that had been badly infested a *Limnæus truncatulus*, which he subsequently found to harbour a peculiar cercaria, the origin of the liver-fluke. This cercaria had the habit of encysting itself on objects; the body became spheroidal and covered by a mucous exudation, presenting granules similar to those which he had observed in follicular organs at the sides of the animal. For some time afterwards he had not been able to find the *Limnæus*; but, on visiting the fields after the floods last July, he had found an abundance of specimens. The floods had cast these snails over the lower lying grounds, and, in receding, had left them there. One cause of the difficulty of investigation was the fact that the *Limnæus* was amphibious. The eggs of the liver-fluke, which was very prolific, passed with the bile into the sheep's intestines, and were dropped over the field. If the ova were dropped into the water or were washed into a ditch, development proceeded. He had watched the hatching of the embryos in water. The head-end was always turned in the direction of the operculum of the egg; this operculum suddenly gave way, and the embryo escaped and began to move about in the water. It moved very rapidly, and, when in contact with an object, stopped as if examining it. When it came in contact with the right snail, it began to bore into the animal, in which it became embedded. It was not all snails that it would enter; only the *Limnæus truncatulus*. When it had entered the snail, the body contracted and became elliptical; an outer covering of cells with cilia was formed, and the spots, which the embryo had possessed, became detached. It thus became a degenerate spore-cyst, with a number of germinal cells, which increased in number and broke up into rounded masses, the germs of the second generation. These increased in size, became oblong, and provided with a pharynx and intestine, assuming the form of a *Redia*, which forced its way through the spore-cyst. The spore-cyst was developed in the pulmonary membrane of the snail; the *redia* reached the liver and fed on the liver-cells. A further formation of spores took place in the *redia*; one end was formed into a tail, while at the other the cells arranged themselves so as to form a sucker. A *Cercaria* was thus formed, which was very active, until it came into contact with some body, when it became encysted. In this way it became encysted on grass, and was devoured by sheep; it then escaped from the cyst and wandered into the liver of the animal. It might be asked whether and how far this investigation would lead to the prevention of the disease. Mr. Thomas believed that it would. The real preventive was salt, which, in a solution of 0.75 per cent., killed the snails. It should be scattered over all spots of soil infested with the worm. It was also very advantageous to feed the sheep on salt. Mr. Heath, a veterinary surgeon, had divided a healthy flock into two parts. Both flocks were placed in an infested pasture-ground. To one he gave daily half-a-pint of corn with half-an-ounce of salt, well mixed. When they were killed, in the next summer, not one of the sheep that had been fed with salt had a single fluke; while of the others, not one was free. It was long

known that salt prevented the disease; but its action was not understood, and farmers were slow to use it. When the sheep had once become infected, there appeared to be no real cure; the only thing that could be done was to keep up the strength of the animal.

Dr. COBBOLD remarked that he had been interested in the subject many years. Even the elephant and giraffe were affected with flukes, and these were also found in whales, dolphins, and porpoises. He thanked and congratulated Mr. Thomas for his researches. Before Mr. Thomas announced his discovery (and it was a real discovery), it had been stated that Professor Leuckart had found that *Limnæus truncatulus* was the intermediate host of the liver-fluke. It had, however, been ascertained that the snail on which Leuckart made his experiment was not *Limnæus truncatulus*, but *Limnæus pergeri*. In Leuckart's experiments, the snails were infected, but the embryos did not arrive at the cercarial stage. It was reserved for Mr. Thomas to throw a flood of light on the subject, and to work out the entire process of development; and it would be an honour to him to have his name associated with that of Leuckart in the work.

Dr. GEORGE HARLEY said that in 1879 a labourer, set 52, was admitted into the Dorset Hospital with anomalous symptoms. He had pain in the region of the liver, with sickness, but no jaundice; there was also abscess. He died in four months. At the necropsy, twenty-six flukes were found in the hepatic duct. He had not been in the habit of eating meat; his ordinary diet consisted of bread and cheese, with which he often ate water-cress.

Dr. T. J. MACLAGAN said that a gentleman, residing near Dorchester, had informed him that in 1879 and 1880, when many sheep were lost, the whole of a flock that had been fed with corn and salt was preserved.

The PRESIDENT, in expressing the thanks of the Society to Mr. Thomas, said that his researches clearly showed the close relation between diseases of man and those of animals; much might be expected from their combined study. They also pointed to the extreme importance of prevention in preference to attempts to cure.

Specimens.—The following microscopic specimens illustrated the discussions.

Dr. COBBOLD showed: 1. Specimens of *Bilharzia hematobia*; 2. Eggs and living embryos hatching out (the living embryos were very active in this specimen); 3. *Distoma heterophyes*, the small Egyptian fluke, from the only known case (presented by Professor Leuckart); 4. *Anthomyia* or *Homalomyia scalaris*, from the human intestine (this parasite has been figured, but not named, by Dr. Lionel Beale). Dr. Cobbold also exhibited Lung-sputum full of fluke's eggs; Human liver with flukes; *Filaria Bancroftii*, in the adult state, commonly spoken of as the *Filaria sanguinis hominis* of Lewis, removed from a tumour (helminthoma elasticum) of the axilla by Dr. Bancroft; Five samples of urine containing eggs of *Bilharzia* from patients from Egypt and Natal.

Dr. RADCLIFFE CROCKER showed: 1. Ova of *Bilharzia hematobia* from blood from bladder of a boy set. 12; 2. and 3. Ova and embryo in process of hatching.

Dr. BASTIAN showed: 1. *Trichina* from the muscles of a wild boar; 2. *Syngnathus* (a nematode allied to *Pleodera*, causing tubercular nodules in the roots of cucumbers); 4. Embryos of guinea-worm (*Dracunculus*), stained with Bismarck brown.

Dr. STEPHEN MACKENZIE showed: 1. *Filaria sanguinis hominis* (embryo), from stomach of Australian mosquito; 2. The same, from stomach of Chinese mosquito; 3. The same, from human blood; 4. The same, embryos stained to show sheath.

Mr. A. P. THOMAS showed specimens of the liver-fluke in sheep (*Fasciola hepatica*): 1. Eggs of *Fasciola hepatica*; 2. Free embryo; 3. The same, stained with picro-carmin, the embryo being very transparent; 3. *Redia* (one of the nurse-forms of the liver-fluke), containing cercariae and germs of cercariae; 4. Cercariae of the liver-fluke killed in the act of forming their cysts. Also specimens of the shell of the univalve mollusc *Limnæus truncatulus*, the intermediate host of the fluke.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.
MONDAY, NOVEMBER 6TH.

Mr. S. LEE RYMER, President, in the Chair.

SOME interesting casual communications were made by

Messrs. A. Coleman, Chas. Tones, and Redman. The latter showed an upper molar, the pulp cavity of which was almost completely filled by a mass of secondary dentine. The patient, a lady, had suffered for several years from acute attacks of pain, which she referred to this tooth; but it appeared so perfectly sound that none of the dentists whom she had consulted would consent to extract it. Mr. Redman also could find no evidence of anything wrong until he directed a very strong light upon it. He then noticed that, whilst the neighbouring teeth appeared slightly translucent, this one was opaque; he therefore diagnosed calcification of the pulp, and an examination after extraction proved this to be correct.

Dr. ALFRED CARPENTER, of Croydon, read the paper of the evening, entitled

A CONSIDERATION OF SOME OF THE CAUSES WHICH LEAD TO DENTAL DECAY.

Dr. Carpenter first traced the history of dental caries, so far as it could be gathered from early writers and from a careful examination of ancient burial-places, showing that, although never so generally prevalent as it was now, caries was not a new disease, and that the evidence thus obtained went to prove that luxury, indolence, and vice tended very much to promote the development of this disease. He then went on to discuss some of its predisposing causes. There could be no doubt as to the effects of inherited tendencies, such as the syphilitic and gouty, or of others of a less distinctly-marked character, which showed themselves in the form of defective nerve power, or of inefficient nutritive force. These, then, were the consequences of accidental injury to the fetus, or young child, to wear and tear of the organ itself, to improper diet, and other causes, which might be conjoined with the hereditary tendency, and produce still more serious results. Most of these causes acted chiefly in early life, but improper diet was not an uncommon cause of disease of the teeth in later life. The most marked example of this was seen in the loss of the teeth from scurvy, but less striking cases were frequently met with in which loss of these organs were caused by gouty inflammation of the periodontal membrane, brought on by indulgence in a too highly albumenised diet. Dr. Carpenter then discussed in turn the effects produced on the teeth by hereditary tubercular syphilitic strumous and gouty taint. The bad results of the first seemed to be due to imperfections of growth, certain groups of cells undergoing fatty degeneration instead of the normal calcification, producing structurally weak dentine, in which caries made rapid inroads unless promptly checked by proper treatment. Syphilis and struma produced marked effects upon the teeth, as they did upon other parts of the cutaneous system. The effects of the gouty diathesis were not so distinct, which might be due to the fact that the disease was not usually fully acquired until an age at which procreation had ceased. Of the effects of the rheumatic diathesis upon the teeth little was yet known. In conclusion, he called upon the dental profession not to be satisfied with improving their methods of treatment, but to look forward to the time when the prevention of disease would be considered by the dental surgeon of greater importance than its radical cure.

The discussion on the paper was postponed until the next meeting.

WE are happy to notice the steady decline in the epidemic of typhoid in Paris, which last week was further reduced to 112 fatal cases, against 250 three weeks previously. Diphtheria appears to be on the increase in several Continental and American cities, notably in Berlin, St. Petersburg, and Baltimore.

In our obituary column of to-day will be found an announcement of the death of a very venerable and much-respected member of the profession at the age of ninety-two. The deceased, Dr. Francis De Grave, had retired for many years to Croydon, where he resided at the house of a relative. He was at one time President of the Society of Apothecaries.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLIAMS and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 6½ dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 22, 1882.

HYGROMA.

It would be wholly incorrect to speak of the advance of medicine and surgery as being characterised by the discovery of new diseases, because it is impossible for us to imagine a condition of mankind with which existing forms of illness would be unassociable. There can be no question, on the other hand, but that in former times the general *facies* of human ailments has differed materially from that distinctive of our own period; whilst it is equally certain that in the ages to come familiar diseases of to day will yield to other and now unknown forms, whose evolutionary phases lie impenetrably hidden in the mysteries of futurity. Why this is so, and how it is, we owe the understanding of to the mighty genius of him who gave new life to latter-day biology, and through his magnificent conception, in its universal applicability, enabled even the pathologist and the physician to elucidate, by aid of the hypothesis of evolution, very many of the darkest problems of disease. Now the philosophical student of physical signs, exhibited during life and after death, is armed with the means of ascribing something more to them than a merely indicative value to guide him to the experimental application of the particular empiricism he affects. Rather they become for him the record of a series of changes of indefinite extent, but of very definite tendency; and he knows, too, that accordingly as he reads, aright or incorrectly, the story these signs are able to reveal he is approaching towards, or receding

from, the goal of his aspirations, a perfect system, namely, of otiology.

But, although the duration of the historical period is of too limited a nature to permit our accepting the idea that new diseases have arisen within it, it is yet abundantly clear that each step in advance in scientific medicine is marked both by a fuller appreciation of the signification of recorded facts, and the recognition, sometimes for the first time entirely, of forms of disease which either occur unfrequently, or have been hitherto confounded with others of like appearance. There are many reasons why we are compelled to accept the latter explanation as applying in reality to all such cases; and even also in those diseases which almost seem to be created *de novo*, to attend the introduction of new industries or a new mode of living. Within recent dates the history of myxœdema affords an example of this confusion of diseases, and without mentioning many that will occur to each reader of this page, "hygroma" may be cited as a somewhat older but not less typical instance.

The reflections indulged in above have been suggested by the report of cases of "congenital cystic hygroma," read to the Medical Society of London by Mr. Edmund Owen, F.R.C.S., on the 6th inst. Mr. Owen refers to a description of the subject of his paper contributed in 1839 to the Medico-Chirurgical Society by Mr. Cæsar Hawkins; and which he regards both as the first treatise on the subject, and the most complete, pathologically. The tumours to which this term "hygroma" is given are cystic in character, and, in so far as they appear to be usually filled with a pellucid fluid, deserve the name they have received. In the Clinical Society's Transactions for 1880 (vol. xiii.), Mr. Thomas Smith records two cases of congenital cystic hygroma, successfully treated by the induction of local inflammation by the agency of fine silk setons. Both he and Mr. Owen regard the disease as not very uncommon, and express surprise that it is not more generally described in works on surgery. If their conclusions are correct, it is indeed surprising that so little is heard respecting a disease which carries with it such evident and dangerous symptoms as these so-called hygromata. It is difficult to imagine that two surgeons, to each of whom cases are even frequently brought, should monopolise the treatment of a disease, and hence it seems very necessary to discover a sufficient reason for the silence of other observers.

These either do not discriminate any remarkable evidences of unusual classificatory value in the tumours, and unhesitatingly rank them with other and more familiarly named growths, or they fail to accept the distinctions conferred by the possession of so circumscriptive a title as "cystic hygroma." In this we cannot help being, to some extent, in sympathy with them, for even in its strictest etymological meaning the term hygroma scarcely seems to be happily used in connection with a cystic tumour. The invention of the affix *oma* was never intended to cover the mass of confusion it serves to cloak under existing arrangements. It is doubtful if a thought is ever given, when it is being delightedly applied to this, that, and the other root, to the fact that its utmost limitation includes so much as, and no

more than, its original form, *ow*, to make. Much as we are indebted to Virchow's nomenclature, the olla podrida of growths included under his *omata* tends oftener than not to perplexity and confusion.

In the twelfth volume of "Transactions of the Clinical Society" there is recorded a case under the care of Sir James Paget and Mr. Norton which, in the light of strict appropriateness, is much fitter to be described as a hygroma than any to which the term has yet been applied. In this case the patient, a lady, was long troubled with copious discharge of a thick, watery fluid from one nostril. As much as sixteen or twenty ounces might thus be lost *per diem*, and after some time Sir James Paget cured the excessive flow by the employment of zinc sulphate internally, and as a wash. Subsequently, the patient having died from another cause, post mortem examination of the skull was made, under the impression that the discharge might have been from the intra-cranial cavity. Nothing was found, however, to confirm this view, but on the wall and floor of the left antrum were found several polypi, which resembled very thin-walled cysts, but were, in reality, masses of very fine membranous or filamentous tissue infiltrated with serum. Other masses, presenting the appearance of collapsed, degenerated polypoid growths appeared, and so unusual was the whole structure that it was preserved, and may now be seen in the museum of the College of Surgeons.

As a "maker" of moisture—the literal meaning of hygroma (*ὕγρως*, moisture)—this example of polypus of the antrum is unequalled; but it was not, properly speaking, a cyst at all; nor is it reconcilable with pathology and etymology both to speak of a "cystic hygroma" under the character of a continuously existing tumour. The pathology of these bodies, too, notwithstanding Mr. Owen's inspiring confidence in the prescience of Mr. Caesar Hawkins when writing for us forty years ago, is still capable of receiving explanation to make it more completely "understood by the multitude." By Mr. Owen's own discovery, the majority of practitioners are shockingly neglectful of "congenital cystic hygromata." Would they be so if the "pathology, diagnosis, and treatment" of the disease were as well known as they ought to be if forty-four years have added nothing to our knowledge of them?

MEDICAL OFFICERS AND HONORARY QUEEN'S CADETSHIPS.

THE subject brought to notice by the question which Dr. Lyons, M.P., addressed to the Secretary of State for War with reference to the exclusion of the sons of medical officers from the privilege of obtaining honorary Queen's cadetships in recognition of the "long or distinguished service" of their parents, is but another phase of the "combatant" and "non-combatant" grievance to which, in relation to sick leave and half-pay resulting from wounds or ill-health, the attention of Mr. Childers has been called more than once, and which the right honourable gentleman promised nearly two years ago to take into his consideration.

Two years in the official life of a cabinet minister, threatened with the vicissitudes of popular favour, is a very long span; and it is not unreasonable that the many whose prospects are so seriously involved should expect either a distinct refusal based upon substantial grounds, or a liberal concession, the result of that mature reflection for which there has, without doubt, been ample time. Should any longer period elapse without some utterances on the part of the Secretary of State in redemption of his promise publicly given to Mr. Findlater, M.P., in March, 1881, or should Mr. Childers during a further postponement, as rumour suggests, pass to another department of the State, leaving his pledge unfulfilled, medical men must learn the unpleasant truth that official veracity is to be relied on only in proportion to the number of votes imperilled by a broken vow, and that at present the chief main-spring of honour is the caucus. The word "combatant" in its original meaning, no doubt, denoted those who came into personal conflict with the enemy, and certainly this signification could not embrace the duties of medical officers; but of the thousands who have of late received medals and decorations, how many could be said to have ever been within striking distance of the foe?

To exclude, therefore, the members of a department whose duties compelled them to be present with the fighting line at Tel-el-Kebir because they had not been sent into that dangerous position for the purpose of personal encounter, is to seek, by adherence to an obsolete title, to deprive medical officers of the privileges and advantages for which they have in all justice qualified.

LIMITATION OF OVER-POPULATION.

THE difficulty of providing for an unlimited family with a limited income is felt in all civilised countries, where the unhappy *pater familias* too often realises the truth of the Irish lamentation, that "children are not pigs, and don't help to pay the rent." We find the difficulty encountered in different ways in different places. In these countries and in most parts of Europe Nature is allowed to take her course; and a long, weary, and too often a losing, struggle is bravely kept up by many an unknown hero or heroine. In France, and in parts of the United States, particularly among the native Americans, the families are seldom allowed to exceed three or four; and in each of these countries the object is accomplished in a different way. In France well-known preventive means are employed; but in the United States the difficulty is often approached by systematic abortion, which we fear we must add is not entirely unknown to certain members of the medical profession. In the Proceedings of the Detroit Academy of Medicine of the 7th of last March, reported in the *Detroit Lancet* of last month, a paper on "Abortion" was read by Dr. Petershausen, and was followed by a discussion, in the course of which Dr. Noyes is stated to have said:—"I will mention a case that came under my observation. Within two years, a young man, prospectively

deh, married a young woman, prospectively rich ; they were married but a short time when he came into my office and said he was in distress. I asked him what was the matter. He says : 'My wife has missed her turns, and she declares she will not eat or drink until they are brought about. She says she will die before allowing this thing to go on.' This is only one of hundreds of such cases. *As I have said, I have never produced criminal abortion in my life.* I asked him how long she had passed her time. He said, 'about two or three days.' 'Well,' I told him, 'just let her sit in a tub of hot water, and give four compound cathartic pills.' That is all I said. Whether she did use the hot water and pills or not I do not know, but the turns came on all right. I mention this case as a striking illustration of cases that could be adduced if only known. As I said before, why is it that even the wealthy and the educated resort to this thing, who are able to bring up children in good health? There must be some cause for it. It seems to me preaching from the pulpit is sadly lacking in these days. These persons are members of churches ; some of them are ladies in society ; in the church-work of churches ; they hear nothing from the pulpit but the great evil ; society is poisoned from top to bottom. I have known ministers apply for means of prevention of having children. Dr. Andrews mentions a reason, and a very plausible one—that the husband does not want children because it forbids greater indulgence in sexual appetite ; and I think the woman does not want to be laid up or kept out of society, as they say it spoils the figure. We all know these things exist."

This is pretty plain speaking, and inference made tolerably plain (whether so meant or not), both to professional and lay hearers. Still more remarkable are the observations of Dr. Cleland, who said :—"A very common way among women is the hot water douche. They will buy a large fountain syringe and sometimes use it for hours at a time, and ultimately bring on expulsive pains. I think, as far as my observation goes with women in that way, it is the most innocent way and least likely to induce trouble." Another speaker described the case of a young lady who consulted him for painful menstruation ; and in whom, on examination, he discovered what he thought was a congested and tight os, but which was in reality the early stage of pregnancy. He dilated this os, and abortion instantly followed. He concluded his case by a complaint that he had thus been "taken in by this young girl,"—who evidently had had some very effectual advice, medical or otherwise, as to the best method of getting out of her difficulty. It is but right to add that each and every speaker deprecated in the strongest manner the idea that he would have anything to say to criminal abortion ; and one of them put the case in the following clear way :—"If the people had this matter properly presented to them by the physician, this crime would not be so frequent. Intelligent people very many times have no idea of the thing they are asking the physician to do for them. A woman comes to me, says she has too large a family—too many children ; she supposes herself pregnant again. If I say—'Very well,

the older children cost the most, and you have too many children, just bring your eldest little boy and we will shoot him,' it presents it in a very different aspect."

We have read the whole discussion with pain, for it plainly proves that abortion for the decrease of population, one of the cardinal sins of the decayed Roman Empire, is making way among a certain class on the other side of the Atlantic. In the United Kingdom abortion is sometimes produced to save the life of the mother, and mostly where a contracted pelvis renders delivery impossible, and in cases of dangerous exhaustion from continued gestative vomiting. It is always done after proper consultation, in the open light of day ; and the child's life is always, if possible, saved. No medical society in these countries would listen to some of the speeches delivered at the Detroit Academy ; nor would any of our profession undertake abortion unless legitimately, properly, and under the conditions just described.

Notes on Current Topics.

The Academy of Medicine of Ireland.

THE penultimate and most important step in the formation of the Academy was taken on last Saturday when the Fellows met to elect Sectional Councils and Honorary Officers. It had been already decided that there should be four such Councils to preside respectively over the Sections of Surgery, Medicine, Pathology, and Obstetrics, there being also Sub-Sections in Anatomy and Hygiene. Each of these Councils consists of ten Fellows, and each will elect a Secretary and two other of its members as delegates to the General Council of the Academy. As we have said, the Sectional election took place on Saturday, and over one hundred Fellows voted, none being permitted to do so who had not paid their subscription of two guineas. For the Surgical Council there were fourteen candidates, the President of the College of Surgeons being *ex officio* President. The following gentlemen were successful :—Messrs. Colles, Porter, Hamilton, Stokes, H. G. Croly, Mapother, Wheeler, A. H. Jacob, O'Grady, and Thornley Stoker.

For the Medical Sectional Council there were twelve candidates of whom the following were chosen. The President of the College of Physicians being *ex officio* President of the Section, viz. : Drs. Gordon, H. Kennedy, Grimshaw, J. W. Moore, J. H. Benson, Finny, C. Nixon, Cameron, R. Hayes, and A. Montgomery.

For the Pathological Council there was no contest, the following ten candidates only having offered themselves :—Messrs. MacDonnell, Foot, Corley, T. E. Little, Duffey, Coppinger, Story, Abraham, Bennet, and W. Smith. Dr. J. M. Purser was chosen President.

In the Obstetrical Section the contest was hottest, there being two candidates for the Presidency, Drs. Denham and Kidd, for the presidency, and fifteen for the ten seats on the Council. Dr. Denham was elected President, and the following for Council :—Drs. Johnston, Athill, Macan, Kirkpatrick, Madden, Churchill, Jones (Cork), Purefoy, Neville, and W. J. Smyly. Several of the

members of the Council of the Obstetrical Society who had resisted the proposal to merge the Society in the Academy lost their seats.

The Sectional Councils will meet at once to elect their secretaries and delegates to the General Council, and the Academy will, we believe, be in a position to hold its first Sectional meeting at latest on next Friday week.

A New Electrical Danger.

OUR contemporary *Iron* draws attention to the promise held forth by theatrical managers of new effects to be introduced into this season's pantomimes with the aid of electricity. The plan held in view is, it seems, to arrange manners so that the tinsel splendours associated in the past with fairies' dress and surroundings, shall give place to actual points of light emitted from electric lamps constructed for the purpose. That the effect thus produced will be unusually brilliant and beautiful there can be no question; but the possible cost at which the improvement must be made is of a nature to raise the strongest feelings against its adoption. The pecuniary outlay involved is the least consideration in this respect, and one, too, on which managers may be safely allowed to embark at their option; but the risk to life is quite another and a far more serious matter. In order to produce the promised result with electricity, free use of conducting wires—all more or less exposed, because all subject to constant motion—must be made, and thus the probabilities of even fatal accidents will be increased a hundredfold as compared with former years. An impossible suggestion has been made to the effect that the electricity required for personal illumination in pantomimes shall be supplied by means of accumulators carried by the performers—a mode of obtaining it unlikely to succeed until a much more portable accumulator than any yet devised has been invented. In the interests of public safety, therefore, it is urgently necessary that a prompt and efficient expression of adverse opinion should convince the more enterprising theatrical caterers that their proposal to enlist the services of electricity in a way that will grievously endanger the lives of their *employés* is repugnant to the better feeling of their patrons, as it is unmistakably inimical to safety.

Royal University of Ireland.

THE Senate of the Royal University have adopted the following regulations with respect to the student-ships:—The first examinations for student-ships shall be held in the autumn of the year 1883. In 1884 one studentship shall be awarded for proficiency in Experimental Physics and Chemistry, and the courses for the examinations shall be those which shall be prescribed for the examinations for the M.A. degree in that year in those subjects respectively. In 1885 one studentship shall be awarded for proficiency in Biology (including Physiology, Zoology, and Botany), and in Geology (including Mineralogy and Physical Geography).

Medical Courses.—The following alterations as to the courses for medical examinations were enacted:—1st. As to certificates of acquaintance with mental diseases, candidates will not be required to produce certificates of having attended courses of lectures on those diseases; but every candidate for the M.B. degree will be required

henceforth to produce a certificate of attendance for three months in a recognised lunatic asylum where clinical instruction is given. 2nd. After the year 1883, all candidates for the degree of M.B. shall be required to exhibit proficiency in the use of the ophthalmoscope and laryngoscope. 3rd. After the year 1883, all candidates for the degree of M.Ch. shall be required to present a certificate of having attended a three months' course of lectures on Operative Surgery. 4th. After the year 1883, all candidates for the degree of M.Ch. shall be required to pass a special written examination.

Lady Students of Science and Medicine.

WHATEVER explanation may be accepted of the fact, it is indisputable that the successes gained by female students at the outset of the movement in favour of admitting them to equal examination with males have not been maintained. In the Cambridge University Higher Local Examinations a marked decrease is yearly observable in the number of women who succeed in passing in the Natural Science group of subjects. Moreover, it would seem as though women are generally recognising the fact of their being better fitted to pursue other branches of study than the purely scientific, for in each year, though the total number of candidates for the Higher Local Examination increases, yet a steady diminution is going on in the numbers who take up the science papers. Thus, the total entries for examination were 882 in 1881, and this year 961. During the last three years, however, the number seeking to pass in the Natural Science division of the examination have shrunk from 99 in 1880 with 26 failures, to 39 in 1882 with 9 failures. In 1882, 17 failed out of 89 who presented. The examiners report that the candidates seemed to be at a loss respecting the meanings of the terms they employed in their answers; and in physiology very serious mistakes were commonly committed, and that too in matters of the utmost importance. Perhaps the most significant fact of all, however, is, that in September last a supplementary local examination was held for the convenience of candidates who sought to avoid the University Previous examination; some of these also, who intended to enter on the study of medicine. Of the latter class of students 19 entered for examination, not one of whom was able to satisfy the requirements of the General Medical Council in respect to registration.

A Retractation on Compulsory Notification.

It is an admitted fact that until the question of compulsory notification of infectious diseases by medical men was first mooted and resolutely opposed in these columns, the profession was quite unaware of the cankerworm which was making its insidious progress in their midst. Certain of our contemporaries ignored it altogether, and such of them as were subsequently compelled to refer to it—the *British Medical Journal* and *Lancet* to wit—sang psalms of joy in its favour, and commended it to the hearty acceptance of their readers. But gradually a little light was let in here and there from the practical experience of the one or two towns on which the Act had been ignorantly forced, and the profession began to perceive what an iniquity so-called sanitary legislation was capable of producing, and that our denunciations were the outcome

of personal knowledge and an earnest desire to protect their interests directly, and those of the public indirectly. We are, therefore, truly glad to be able to quote from the *Journal* of the British Medical Association (which was one of the strongest of compulsory notificationists) the following virtual recantation :—

Nothing can more strikingly illustrate the practical difficulties that surround the question of the compulsory notification of infectious diseases, than the result of proceedings in Liverpool, of which we published a report in a recent number. It is a very significant fact, and one which points strongly to the desirability of a full parliamentary discussion of the subject, that on this, the first occasion, when a decision has been come to after the consideration of evidence gleaned in towns subject to compulsory Acts, which, though *ex parte*, are not obtained entirely from those favourable to compulsory notification by medical men, it is practically opposed to any scheme which embodies that principle. The deputation from Liverpool wisely heard some few of the general medical practitioners of the towns which they visited ; and where this was done the existence of such an amount of "friction" was made manifest, as to render it obviously necessary that serious modifications be introduced into any system yet in force before it can be hoped to make it generally satisfactory, either to the medical profession or the public. It is very significant that the Vice-Chairman of the Health Committee of Liverpool, who last year made strenuous efforts to carry through a Bill to impose indirect compulsion on the medical men of that city, should this year be one of its strongest opponents, and should be reported to say, "Anyone who read the whole of the evidence," i.e., the evidence collected by the Liverpool deputations, "would come to the conclusion that the system in the towns where it was nominally compulsory was, in reality, voluntary, for the authorities winked at the infraction of the law ;" and that to impose compulsory notification on medical men was shown to be "neither equitable nor expedient."

The Unqualified Assistant System.

We are glad to find that the suggestions made in the articles on the unqualified assistant system which appeared in this journal earlier in the year, are being followed with the result pointed out by us. The advice we gave was, that whenever patients were imposed on by practitioners palming off on them the services of unqualified assistants, payment for visits so rendered should be steadily refused. In the City of London Court such a case came recently before Mr. Commissioner Kerr. In this instance, a medical man sued a patient for three guineas for professional attendance. One of the witnesses for the plaintiff was an unqualified assistant of the latter, who, in reply to a question from the magistrate, described himself as *sine diploma*, admitting at the same time that he, as well as his employer, had visited the defendant professionally. Mr. Commissioner Kerr at once decided that that practice was illegal, since the law insisted that no medical man could recover on account of services rendered by his unqualified assistant ; judgment was accordingly entered for the defendant, with costs.

It is impossible to exaggerate the importance of this ruling, or to over-rate the influence it may probably exercise in helping to crush out of existence the worst features of the unqualified assistant system. We trust that the widest possible publicity will be given to the case referred to, and that every person who may discover a similar imposition being practised on himself, will adopt a

like course of action to that pursued by the defendant referred to, and decline payment for services improperly and illegally rendered.

Erasures from the Medical Register.

THE Registrar of the General Medical Council has issued on behalf of himself and the Branch Registrars a notice, which will be found in our columns, to the profession at large, reminding them of the peremptory necessity that each practitioner shall notify to the Branch Registrar any change of address which he may make. Any man of business habits will naturally make this notification in order that he may appear in proper form in the next year's issue of the Register, but those who are too indolent to do so may be induced to comply with the Registrar's request when we remind them that by omitting to do so they leave themselves open to have their names erased altogether from the official list, and to lose thereby most of the privileges which they possess as registered practitioners. It is the duty of the Registrar, under the Act, to send letters of inquiry to every one who is believed to have disappeared, and—in case he gets no reply—to strike the name out of the Register, and if—with the knowledge that this must be done—any practitioner will not take the trouble to reply to the Registrar's communication, it serves him right, in our opinion, that he should lose his privileges.

Honours to the Army Medical Officers.

We are glad to be able to announce that the omissions in the list which Sir Garnet Wolseley submitted to Her Majesty for honours or promotion on the conclusion of the Egyptian campaign have been filled in, and that the Medical Department is now fairly represented amongst the recipients of honour in the official *Gazette* just issued. First comes Surgeon-General Hanbury, who will henceforth bear the title of Sir James Hanbury, K.C.B., the Queen having been pleased to approve of the bestowal of this honour on the head of the Medical Department of the expedition. The following are to receive the dignity of C.B. (Companion of the most honourable Order of the Bath):—Deputy Surgeon-General Colvin Smith, M.D., who was in medical charge of the Indian Contingent ; Deputy Surgeon-General James Ekin, M.D. ; and Surgeon-Major John Henry Beath, M.D. The following promotions have been also gazetted :—Brigade-Surgeon Jeffrey Allen Marston, M.D., and Brigade-Surgeon William George Nicholas Manley, to be Deputy Surgeons-General ; Surgeon-Major John Sarsfield Comyn, M.B., and Surgeon-Major Byng Thomas Giraud, M.D., to be Brigade Surgeons ; Surgeon-Major, with relative rank of Major, Thomas Francis O'Dwyer, M.D., and Surgeon-Major, with relative rank of Major, Laurance Corban, M.D., to be Surgeons-Major, with the relative rank of Lieutenant-Colonel ; and Surgeon John Godfrey Rogers, M.B., and Surgeon Benjamin Bloomfield Connolly, to be Surgeons-Major.

FROM the report of the Medical Officer of Health for Hastings just to hand, we learn that the death-rate during the past quarter was only 12·38 per 1,000 in a population of 44,000. This will compare favourably with any other health resort in the United Kingdom.

Metropolitan Water Supply.

DR. FRANKLAND reports that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies during the past month was in every case inferior in quality to that of the previous month. How could it be otherwise, when it is recollected that for weeks past the whole of the low lands situated above the intake of the water companies have been constantly flooded, and that with every partial subsidence of the flood tons weight of manure and all kinds of filth have been swept into the Thames, and which no filtration can be expected to remove. Nevertheless it is the kind of contaminated water London is compelled to pay for and drink. Can it be wondered at that typhoid fever is very rife at this moment?

Public Health Law in England and in Ireland.

WE read that the Local Board at Sandbach, near Crewe, have recently been threatened with dissolution for neglecting their duty. Some time ago the Local Government Board drew their attention to the fact that a supply of wholesome water was much needed for the town, and pointed out the grave responsibility which would rest upon the members should any evil consequences arise from their neglect. As the Sandbach Local Board took no notice of this warning, the clerk has just received a communication from the central authority stating that, if the Board does not at once move in the matter, it will become the duty of the Local Government Board to take steps for dissolving the urban authority of Sandbach, and resolving it into a rural sanitary authority. To those who know the extent and value of the public health system of Ireland, as administered by "gombeen" guardians, under the superintendence of the Irish Local Government Board, this paragraph is very entertaining.

In England a sanitary authority is threatened with dissolution because it omitted to provide a water supply for its district. In Ireland the wildest sanitary enthusiast would not venture on such a revolutionary suggestion as that a sanitary authority should trouble itself about so unimportant a matter as water supply. Probably there are not three boards of guardians in Ireland which could soar to such a consideration, most of them not being up to the level even of clearing the pig out of the parlour, the fowl out of the bedrooms, or the manure heap out of the parterre. But if they did rise to consideration of water supply, it would not in the least surprise us to find the Irish Local Government Board tabooing their action, and objecting to their expending money on such a luxury as clean water. The real truth is that the public health system in Ireland is a discreditable sham, in which the medical officers of health are forced to occupy a very sorry part. That it is a sham, and an imposition on the ratepayers, is the fault of the Irish Local Government Board, and no one else. By every means, legal and illegal, that Board has striven for the last twenty years to save itself the responsibility of sanitary administration, to snub the medical officer of health who displayed any assiduity, and to encourage boards of guardians who resisted the performance of their

duty. This is literally true, and the result of that policy is that Ireland is as dirty, as unhealthy, and as uncivilised to-day as it was twenty years ago, while the medical officers of health are paid an unwilling pittance on the strict understanding that they will give no trouble about sanitary matters. If Parliament cannot deal with the question in any other way, it ought either to sweep away Irish public health law altogether, or else supersede the Irish Local Government Board in supervisory functions which it has shown itself unwilling and incompetent to discharge.

The late Visitations of Examinations.

THE General Medical Council has issued in a complete form, in a volume of 300 pages, the Reports of the Visitors recently deputed by the Council to inspect the examinations of Colleges of Physicians and Surgeons, and the Apothecaries' Halls of England, Ireland, and Scotland. The Reports are prefaced by an introductory statement by Mr. Teale, and are divided into three parts:—I. The criticisms of the Visitors; II. The detailed description of the examinations; and III. The documents, examination papers, &c., which have reference to these examinations. To the Reports are appended the observations made by the respective Colleges upon the criticism of the Visitors, the whole volume being a very valuable contribution to contemporary medico-educational history. We believe that the General Medical Council is especially anxious to have the opinion of competent critics upon the points raised and suggestions made by the Visitors, and certainly the time expended in reading, noting, and discussing this volume will not be lost to those who take an interest in the future of our profession.

The Government and Mr. Wheeler.

IN our recent remarks respecting the parliamentary debate on the claim of the Vice-President of the Irish College of Surgeons for attending Mr. Carter at the request of the Irish Government we confined ourselves to pointing out that—considering all circumstances—the amount claimed by Dr. Wheeler is, in no sense, excessive, and that payment of it could not be resisted either on the ground of its being extortionate, or on the ground that the attendance was given without the full cognisance and sanction of government. On the law, departmental etiquette or precedent, or parliamentary aspect of the matter it is not our business to express an opinion, but we think it right to supplement our observations by saying that, in our view, Mr. Wheeler is fully entitled, as a matter of professional propriety, to demand his fees from Government, and, if refused, to obtain them by any means that the law or parliamentary procedure leaves open to him. We altogether dissent from the view that there is anything undignified in a medical practitioner using all legitimate means to obtain his rights, and we will add that, in our experience, Governmental departments are just as likely to require legal pressure to pay their just debts as any other debtors. We have an abundant knowledge of the readiness of such departments to avail themselves of any legal evasion to escape paying a fair claim, or to force a medical man to perform for nothing what it is his right to be paid for, and we do not think that

a medical man is acting meritoriously in permitting himself to be officialised out of his rights.

We are aware of a comparatively recent case in which two surgeons were sent by the Irish Government to visit at a considerable distance from Dublin, and were put off with a cheque for a little more than the third of their proper reasonable fee. They submitted rather than assert their rights, and we think that they did wrong, because they acknowledged thereby the principle which is now sought to be applied to Mr. Wheeler.

The late Dr. Spencer, F.R.O.S.I.

We understand that a subscription list has been opened for the purpose of presenting the widow of the late Dr. Spencer with a testimonial. Dr. Spencer was for a time Assistant-Librarian to the Royal College of Surgeons in Ireland, and was most courteous in the discharge of his official duties. Mr. Colles, 21 Stephen's Green, and Mr. Blake, College of Surgeons, have consented to receive subscriptions.

Alcoholic Droppings.

At an inquest held at Chester, before the City Coroner, on the 13th inst., it was given in evidence that the deceased, Joseph Carter, who was possessed of private means, had been more or less drunk for forty years. He and his wife and son had latterly been in the habit of drinking together, their beverage consisting of the droppings from the taps of the various vaults in the city, which they purchased at about a shilling a gallon. The inquest was adjourned in order that a post-mortem examination might be made, as the cause of the sudden death of Joseph Carter was somewhat obscure. The extraordinary fact was that he was sober the night before he died, and it seemed as if the temporary suspension of a life-long state of toxicæmia had proved too much for him. The craving for alcohol must be strong indeed when filthy tap-droppings are bought up at a shilling a gallon!

Statistics of Diseases in Prussia.

ACCORDING to the *Deutsch Med. Zeit.*, there were in Prussia on December 1st, 1881, 22,677 persons affected with blindness—at the rate of 8·3 per 10,000 of population. With regard to sex, the rate was 8·4 per 10,000 males, and 8·2 females. The rate amongst Evangelicals (Protestants) was 8·2, amongst Roman Catholics 8·4, amongst Jews 11, and amongst professors of other religions 15·3 per 10,000.

There were 27,794 deaf-mutes, or 10·2 per 10,000; 11·3 per 10,000 males, and 9·1 females. In regard to religion the rates among Protestants, Roman Catholics, and Jews were respectively 9·89, 10·37, and 14·34 per 10,000. The rate amongst professors of other forms of religion was 7·27. Of the separate provinces, East and West Prussia have the highest rate, 18·2 per 10,000; and Schleswig-Holstein the lowest, 5·9.

66,345 persons were affected by lunacy, or 24 per 10,000; the rate in males being 25 per 10,000, and in females 23. Amongst Protestants the rate was 24 per 10,000, amongst Roman Catholics 23·7, amongst Jews 38·9, and amongst professors of other religions 18. The rate was highest in Schleswig-Holstein, 33·7 and lowest

in the Province of Posen, 16·1. On the average, 28·5 per cent. were in asylums or other institutions, the highest percentage being in Brandenburg, 40 per cent., and the lowest in Posen, 13·4 per cent.

Belfast Royal Hospital.

At the nineteenth annual meeting of the Belfast Royal Hospital, last week, the Board of Management reported on the recommendation of medical and surgical staff and a special committee appointed by the board, that it had been decided to establish two new departments in the hospital—one for the treatment of diseases of women, and the other for the treatment of diseases of the eye and ear. The report was, after some dissent and discussion, adopted.

Pumpkin Seeds as a Tæniifuge.

A CONTEMPORARY, the *Pharmaceutical Journal*, gives Dr. Wolff's (Pennsylvania) method of preparing and administering the seeds of the pumpkin (*Cucurbita pepo*), a remedy pretty extensively used in the States for the expulsion of tape-worm. This property seems to be inherent not alone to the common pumpkin, but also to other species of the *Cucurbitaceæ*, and of other countries. Pepo has long been known as an anthelmintic, but it was brought more immediately to the notice of the profession in 1845 by Brunet, who extolled its virtues and published numerous cases which he had successfully treated with it. The peculiar principle upon which its action depends has not yet been uniformly established. It has been variously examined, and found to contain a resin, fixed oil, starch, pectin, protein compounds, free fatty acids, sugar, and even a glucoside. Dorner and other chemists claim to have discovered an alkaloid. Heikel maintained that the active principle is its resinous constituent, and that this chiefly resides in the menisperm; and having separated the resinous extract, he administered seventy-five centigrammes in pills, which expelled the tape-worm. Dr. Wolff's experiments have led him to entertain the views of Heikel; and he took a quantity of recently dried and well comminuted seeds and exhausted them with petroleum benzine—previously proven not to extract the active ingredient—and the residue he repeatedly treated with ether, chloroform, and strong alcohol. The product, on evaporation, was a soft resin of a greenish-brown colour and acrid bitter taste. This resin administered in fifteen-grain doses proved to be an active tæniifuge. As, however, neither the resin nor fluid extract was found to possess laxative qualities, it is necessary to administer in two or three hours afterwards a full dose of castor oil.

Promotions in the Royal Navy.

THE honours and promotions which fall to the lot of the Navy Medical Department at the close of the Egyptian Campaign, are of course fewer than those to the sister service. There are no Knighthoods, and but one C.B., this has been bestowed on Fleet-Surgeon Ingham Hanbury. The following promotions in the Royal Navy are gazetted:—Surgeons Charles Cane Godding, Herbert Mackay Ellis, and Evelyn Richard Hugh Pollard to be Staff-Surgeons.

A LEGACY of £1,000 has been received by the Adelaide Hospital, £500 by the Hospital for Incurables, and £500 by St. Mark's Ophthalmic Hospital, under the will of Miss Anna Graydon, of Dublin.

THE Hull General Infirmary celebrated the centenary of its existence on the 12th inst. A temporary erection was used for the first two years, until the present building was opened in 1784. In 1838 a large wing was placed at each end of the building at a cost of £3,000; and more recently there have been added a new block at the back of the main portion, and several detached fever wards.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Brighton 12; Wolverhampton, Leicester 15; Norwich 16; Edinburgh, Newcastle-on-Tyne 17; Bolton, Derby, Halifax 18; Bradford, 19; London' Oldham, Huddersfield, Portsmouth, 20; Bristol, Birmingham 21; Sheffield, Salford, Plymouth, Nottingham, Glasgow 22; Birkenhead, Blackburn 24; Hull, Preston, Leeds 26; Dublin 27; Liverpool, Cardiff, Manchester 28; Sunderland 32.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 27, Bombay 24, Madras 37; Paris 36; Geneva 18; Brussels 18; Amsterdam 25; Rotterdam 27; The Hague 20; Copenhagen 22; Stockholm 23; Christiania 16; St. Petersburg 41; Berlin 23; Hamburg 19; Dresden 21, Breslau 27, Munich 24, Vienna 22, Prague 26, Buda-Pesth 22, Trieste 26; Rome 20; Naples 30, Turin 19, Venice 24; New York 22, Brooklyn 19, Philadelphia 17, and Baltimore 31.

THE annual death-rates per 1,000 in the large towns last week, from diseases of the zymotic class, were:—From scarlet fever, 1·8 in Sunderland, and 3·6 in Cardiff; from measles, 1·6 in Hull, 1·8 in Cardiff, 2·4 in Birkenhead, and 3·5 in Sunderland; from whooping-cough, 1·2 in Norwich and Birkenhead, and 2·1 in Preston; and from fever, 1·1 in Newcastle-on-Tyne, 1·8 in Sunderland 2·0 in Liverpool, and 2·4 in Portsmouth. The 38 deaths' from diphtheria included 19 in London, 6 in Glasgow' and 4 in Edinburgh. Small-pox caused 4 deaths in London, one in Wolverhampton, and one in Newcastle-on-Tyne.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.—The directors of this hospital, at their last meeting, elected Dr. Carmichael, of 22 Northumberland Street, to be one of the ordinary physicians of the hospital. They also elected Dr. Burn Murdoch, St. Bride's, Morningside, to be one of the extra physicians. We congratulate Dr. Carmichael, who is also a lecturer on the diseases of children at Minto House Medical School, on his appointment. We would also suggest that a course of clinical lectures systematically delivered at the hospital would be of immense importance to the students. The advantages which the hospital affords are unfortunately

not fully appreciated by students, who are apparently unaware of the value of a knowledge of the diseases of a large proportion of their future patients.

THE MEDICAL SCHOOL, EDINBURGH.—The classes at the Extra-Mural School, except that of anatomy at Minto House, show a large falling off in numbers this year. This is owing, not to a weakness on the part of the Extra-Mural teachers, but to the tacit recognition by the students of the fact that a sound general knowledge of their profession obtained from sources open to all is not so requisite as being well posted in the crotchets of their future examiners. The great success of Edinburgh as a medical school is certainly due to the powerful vitality of the Extra-Mural School founded a century or more before the Medical Faculty of the University was conceived. This vitality is threatened with extinction, on the one hand, by the weakness of the Colleges, who fail to support the school to which, and not to the intrinsic value of their diplomas, they owe their incomes and existence, and on the other hand, to the concupiscence of the Professors. The truth of these statements is to be found in the fact that a brisk traffic is done in the sale of the Professors' notes. Notes valuable to the taker cannot but give a most superficial knowledge to the purchaser; yet the knowledge so acquired is sufficient to obtain the highest degrees in the University. If the Colleges had the wisdom to see and take advantage of the present state of matters, they could show that their diplomas are of more value than those acquired by the slavish pandering of the unfortunate student to his examiner. To indulge in such a hope in the face of the constitution of the governing body of one at least of the Scottish corporations is an unrealisable dream. As long as men indulge the idea that they owe no duty to the future, and only seek to aggrandise themselves, no hope of progress can be entertained, and one can only feel that a just future will appreciate their acts, and punish them with the contempt they so richly merit.

MEMORIAL TO THE LATE SIR C. WYVILLE THOMSON.—The acting committee of this fund have now resolved to provide a bust for Edinburgh University, and it has been resolved to place a stained glass window in the old church of St. Michael at Linlithgow, of which congregation Sir Wyville was for long a member.

MEDICAL CANVASSING.—It is not too much to say that exact modesty of statement is not expected of a medical candidate for offices vested in laymen in urging his claims. Yet there is a limit to this sort of thing; and the limit has been distinctly exceeded lately in Glasgow in the case of the most recently contested appointments. One well-known and distinguished aspirant after public appointments stated that his "professional standing" was such as to render canvassing unnecessary, when it was well known that the friends of this gentleman were strongly using their influence on his behalf. The gentleman in question has written several papers of a kind, and he modestly assured laymen that he had the satisfaction of knowing that some of them were translated into at least *three* languages. There is one language into which none of them, so far as we know, has yet been translated—viz., the English!

JOHNSTONE.—NEW FEVER HOSPITAL.—The Johnstone Town Council, on the 13th inst., agreed to ask several of the neighbouring local authorities to join with them in the erection of a fever hospital for Johnstone, Kibbarchan, Houston, and Lochwinnoch, in view of the serious epidemic of scarlet fever. Dr. Wilson was appointed medical officer to the burgh.

ST. ANDREWS.—INAUGURAL ADDRESS BY PROFESSOR M'INTOSH.—Dr. W. M'Intosh, the recently-appointed Pro-

fessor of Natural History in the University of St. Andrews, delivered his inaugural address on the 18th inst. His subject was "The Progress of Zoological Science," one of the most conspicuous features of which in recent times, he remarked, had been the fitting out of well-equipped surveying and dredging expeditions by various Governments, and the diffusion of the same mode of exploration on a less costly scale amongst the natural history and scientific societies of their own and other shores. He advocated the erection of zoological investigation stations in different parts of the country, and pointed out there were few cities in this or any other country, so far as was known to him, better adapted on the whole for a combined zoological station and laboratory than St. Andrews. St. Andrews was also finely situated as a centre for researches on the habits and life-history of marine fishes, and it was the nearest University to the Tay, the finest salmon river in this country.

EDINBURGH.—HEALTH OF THE CITY.—For the week ending with Saturday, the 11th inst. the mortality in Edinburgh fell from 96 to 65, and the death-rate was 15 per 1,000. There were 15 deaths under one year, and 19 above 60, of which two were above 80 years. Diseases of the chest accounted for 32 deaths, and zymotic causes for 4. No death was reported from fever or scarlatina, the intimations of these diseases being respectively 17 and 84.

DEATH-RATE OF GLASGOW.—The death-rate of Glasgow for the week ending with Saturday, the 11th inst., was 24 per 1,000 per annum.

PRESENTATION OF AN HOSPITAL TO MUSSELBURGH.—At a meeting of the Musselburgh Town Council, held on the 14th inst., an offer of £700 was made by Mrs. Hope, of Inveresk Lodge (sister of the late Sir David Wedderburn), to build an hospital for the treatment of patients suffering from infectious diseases. It was agreed to tender a hearty vote of thanks to Mrs. Hope for her generous donation.

THE MEDICAL FELLOWSHIPS OF THE ROYAL IRISH UNIVERSITY.

We learn with much dissatisfaction that the Senate of the Royal Irish University, having adjourned the election of Medical Fellows for many months, has at last decided upon a step which illustrates the slight esteem in which they hold our profession. The Senate was empowered—as our readers will recollect—to appoint a number of Fellows at salaries of £400 a year each, it being arranged that, in case salaried officers of the Queen's Colleges were appointed, they should only receive such supplement to their collegiate income as would raise it to £400. Having hatched the Medical Fellowships for several months, they have now decided to grant such honours at the munificent emolument of £100 a year, with the proviso that the Fellows so appointed shall act as Examiners. This determination, coming at the moment when the University has made its *début* as a graduating body chiefly upon the strength of its medical, surgical, and obstetrical graduates, is inexplicable and most ill-advised. The Senate has, in fact, resolved to grant no Medical Fellowships, but to use the powers entrusted to them to create, under the name of Fellow, certain Examinerships, at an emolument which, even or an Examiner, is very insufficient. The Senate is, it appears, about to apply for a Queen's letter to enable it to make eight such Fellows. We understand that the entire proceeding was energetically but unavailingly resisted by the medical members of the Senate, and we think with good reason, inasmuch as the course adopted is a manifest alight to the profession.

IRISH PRISON SURGEONS.

We have reason to know that the working of the medical department of the Irish Prisons Service under the Prisons Act of 1878 and the New Rules formed upon that Act, is anything but satisfactory, and has given rise to much irritation amongst prison surgeons. It is not that there is anything very material to complain of in the rules themselves if they were administered in a liberal and conciliatory spirit, but that they are interpreted and enforced by the General Prisons Board in the most irritating way, every point being used by certain of the inspectors and by the central office at the Castle to gail the medical officers when possible. Hostile reports are made at every hand's turn, and the correspondence thereon couched in uncivil language is passed to the medical officer through the hands of other prison officials. We are not at all disposed to champion any officer who shows an unwillingness to perform his duty cheerfully, or who stands too closely by the letter of the regulations when prison efficiency is at stake; but we know of no medical officer of the department who can be fairly charged with this policy. On the other hand, we protest against the meddlesome officialism which induces certain Jacks-in-office to air their importance at the expense of the medical officer. The Irish Prisons Department has from the first been noted for more or less of this sort of bureaucracy, and—in so far—has shown that those in command are neither diplomatists nor successful administrators.

The Lord Lieutenant of Ireland, Earl Spencer, has made the following appointments to the Viceroyal Court:—As Physicians, Dr. Hatchell and Dr. Nedley; as Surgeons, Mr. Smyly and Dr. Mapother; as Surgeon-Dentist, Mr. Corbet. All of these gentlemen held office during Earl Cowper's Viceroyalty excepting Mr. Smyly, who, however, was one of His Excellency's Surgeons-in-Ordinary during a former tenure of the Viceroyal office.

Correspondence.

HINTS OF EXPERIENCE.—I.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Towards the autumn or winter of life the medical practitioner has acquired many glimpses of things not stated in lectures or text-books, and which might be preserved with advantage for those who come afterwards. As the farmer after the chief labour of the autumn is over retires to his chimney corner in the long and lengthening evenings of winter time, and thinks over the experiences of the former spring or of many preceding seasons, so any intelligent professional man at the sunset of life passes in review his experiences, and finds many things worth noting that were no part of his instruction at college, and are no part of the knowledge of the day. Many of these experiences recorded in memory are suggestive of questions such as "Why is such the case?" there being no doubt in the mind of the questioner as to the facts upon which his query rests. Other experiences are in the nature of observations which may rest on local circumstances and inferences which, though true of those circumstances, are false when generally applied. The observer then who desires to serve a scientific purpose will not place too much confidence in his observations or inferences, but will prefer to say that he *thinks* so-and-so. In this spirit and without dogmatism the writer proposes to record some observations and inferences which seem to him to be true. These will derive interest from the observations of others even if they may be contradicted by the experiences of others. Truth will be served in either case, whether the writer's observations are found to be correct or no.

Experience has led me to think that physiology has not

sufficiently emphasised the relations between man and the lower animals, especially in cases of disease. Anything which affects one of the limbs of a radiate animal has a certain effect upon all, and influences which affect one part of the human body seem specially to affect those parts which are their analogues. Now, in my limited sphere, it has seemed to me that the teeth are the analogues of the ova, and that women with badly-arranged or deformed teeth are usually sterile. On the other hand, where sexual passion is greatly developed decayed teeth are prevalent. The eye and the testicle seem to be analogues of each other; the nose and the penis, or the corresponding organ in the female. The syphilitic poison which attacks the one also attacks the other. The hands and feet are likewise analogues, and the gout that inflames the one is transferred suddenly to the other. The uterus and the stomach, and many other organs, seem to me to have similar relations, of which illustrations crowd upon my mind as I write.

In particular districts of the country medicines seem to me to derive special efficiency when combined with certain agents. For example, in the cotton districts nitrate of potash seems singularly useful in combination with all sorts of other medicinal substances; in the iron districts, sulphuric acid seems to exercise a similar special influence; while in the coal countries nitric acid seems to be specially necessary. It would be interesting to know to what extent my experience in this respect is confirmed by others, and whether any changes, and if so, what alterations time produces.

In my early days, bleeding either from the arm or by leeches, or by cupping-glasses, was considered a life-saving operation in many cases; and as a young dispensary surgeon I have taken bucketful of human blood out at the back-door in a morning from patients who had been submitted to phlebotomy by order of the physicians or surgeons. Now it would be interesting to know whether any, and what consequences, had been observed to arise from the discontinuance of this practice. My opinion has been that the women who were bled most *bred* most, and that large families followed extensive bleeding.

There may be something or nothing in these experiences of past medical work, but they can be sifted and taken for what they are worth.

Yours, &c.,

ALTER BROWN,
Surgeon retired from practice.

Literature.

DR. BALFOUR ON DISEASES OF THE HEART. (a)

In preparing a second edition of this work on Diseases of the Heart and Aorta, Dr. Balfour has been careful to include in it a description of the improvements introduced into this branch of medicine between the dates of the two editions, and has further enhanced the value of each by adding accounts of the progress made by living cases narrated in the earlier issue to the later one. The lectures included in this volume, seventeen in number, deal with the clinical phenomena exhibited during the progress of all well-recognised forms of disease affecting the heart and its arterial outlet. In the opening chapter on the general diagnosis of cardiac diseases, ample instruction and anatomical explanation is given in reference to the meaning of, and mode of eliciting signs of diagnostic value.

In lecture ix., on the variation and vanishing of cardiac murmurs, Dr. Balfour offers a good deal of sound advice to practitioners, many of whom, he very justly remarks, are not at all aware how frequently complete restoration to health may follow after perfect development of regurgitation through either, or even through both valves. The curious phenomenon of variation in the same murmur, which may completely disappear one day to be present again the next, and the failure to appreciate its significance, have sometimes led to erroneous and embarrassing statements of opinion of the most contradictory nature. Perceiving the great desirability, therefore of avoiding this confusion, Dr. Balfour gives directions for conducting a thorough examination of the

heart in such a manner as shall prevent all possibility of deception being caused by such murmurs, and during which the stethoscope need not be employed at all. "If we trust," he urges, "to auscultation alone, as it is generally understood and applied to the heart—that is, if we attempt to diagnosticate the exact nature of any given cardiac lesion by the discovery and discrimination of murmurs, assigning to each its appropriate physical cause in accordance with the position on the cardiac area at which it is best heard, as well as with its rhythm or relation in time to the several acts which constitute a cardiac pulsation, without being actually misled, we shall yet often fail in attaining an accuracy of diagnosis, which is perfectly possible and frequently important." It would do much to clear the future of errors like those witnessed in the past in connection with the treatment of heart diseases, real and imaginary, if every student and practitioner were duly impressed with the value to himself and patients of a right appreciation of Dr. Balfour's warnings and instructions.

The action of digitalis and the general therapeutics of cardiac disease form the subjects of discussion in the fourteenth lecture. The value of strychnia as a stimulant of the intrinsic ganglia is pointed out, and a strong defence of arsenic as a neurotic is presented. Dr. Balfour, moreover, insists that no drug can replace digitalis in the treatment of cardiac disease, and places little trust in ergot and belladonna in this connection. In earlier portions of the book the advantages attending the employment of particular drugs are pointed out under the headings of the various diseases in which they may be adopted with most benefit, the description of angina pectoris and its relief having afforded an opportunity (lecture xii.) of descanting on the marvellous effects produced by nitrates of amyl. Dr. Balfour ascribes these effects, not to a reduction of blood pressure produced by the amyl, but to the action of a volatile narcotic which escapes from the drug with lapse of time, so that only freshly-prepared specimens are potent to afford relief.

The diagnosis of aortic aneurism has a chapter devoted to its consideration, and is followed by another on the iodide of potassium treatment of aneurism, which Dr. Balfour describes as perfectly safe and free from risk, while being equally certain as any more dangerous plan to afford relief. He has "not yet seen any case where relief was not attained, though naturally enough that relief is not always to be got instantaneously, but requires the treatment to be continued for some time." He is, however, towards the end of the chapter, careful to warn us against expecting absolute cure, or indeed anything more substantial than relief, except in favourable cases which come early under treatment, and in which adjuvant treatment, such as rest, &c., can be carried out. Dr. Balfour's words are: "I do not claim that we can perfectly cure aneurism by iodide of potassium, or by anything else, yet I am quite certain that at the present day we possess no other remedial agent or mode of treatment which so surely gives relief, and so frequently prolongs life, as the iodide of potassium."

This work is worthy of the confidence reposed in its teachings, and derives a great additional value from the illustrative cases with which its author assists his descriptions, while at the same time he refrains from unduly crowding his pages with such examples of successful treatment or of suggestive failure. The thoughtful physician could find very much to interest him in the book; every practitioner will gain invaluable instruction from its perusal.

GUY'S HOSPITAL REPORTS. (a)

This will be found to be a most interesting volume of the well-known "Guy's Hospital Reports," and quite up to the level of previous issues. It commences with a paper by Mr. Hilton Fagge on "Purpura Hemorrhagica Accompanying the Growth of Multiple Sarcoma," and including a large proportion of the fatal examples of purpura which have occurred in that hospital for the last twenty years. Mr. Fagge holds strongly to the belief that multiple sarcomata, as in the cases detailed, are often developed in the connective tissues throughout the body, just as a number of nodules of molluscum fibrosum are found beneath the skin, altogether independently of any infective process. One interesting point in the cases recorded in this com-

(a) "Clinical Lectures on Diseases of the Heart and Aorta." By George William Balfour, M.D. St. And., F.R.C.P., Ed. &c. Second Edition. London: J. & A. Churchill.

(a) "Guy's Hospital Reports." Edited by H. G. Howe, F.R.C.S. and Frederick Taylor, M.D. Vol. xiv.

munication is that in two of them (the patients being men), the thymus gland was enlarged, and apparently infected with the growth.

Dr. Stevenson contributes an interesting account of the "Origin of the Three Common Thermometric Scales," and mentions the fact—not generally known—that Fahrenheit originally made use of the temperature of the axilla or mouth of a healthy man (96°) as a basis of his scale. We are glad to mention incidentally that medical men, who have so often been accused of an ignorant conservatism in their favouritism of the old Fahrenheit scale, are at last tending towards the universal adoption of the more recent and much more convenient scale of Celsius, known as the centigrade scale.

Mr. Davies Colley contributes a short paper on "Reduction *en masse* in Ilium," in which he gives the details of three most instructive cases. We are inclined to believe that this accident is of much more frequent occurrence than is generally supposed, as surgeons are usually not disposed to place on record cases of a fatal nature, even though the untoward result might not be in any way attributable to their unskilfulness. We are not aware that any writer has pointed out, as Mr. Colley has done, the risk of returning the intestine into an extra-peritoneal pouch, and we agree with him in thinking it very important that these cases should be placed on record, so that others may be made aware of the possibility of such an occurrence.

Mr. Carrington gives us some information about the "Anatomy of the Triangular Ligament of the Urethra," and clearly establishes the fact that the posterior layer is formed by the obturator fascia, contrary to the statements found in most of our anatomical text-books.

The volume contains many other papers of great interest, to which want of space prevents us from alluding, and it concludes with an inquiry into the "Physiognomy of Phthisis by the Method of Composite Portraiture," by Messrs. Galton and Mahomed. The method of producing these composite portraits has already been well described elsewhere, but we may mention that they are made from the individual negatives by throwing upon a photographic plate disposed in a special form of camera, the images of several negatives in succession, an equal fraction of time being given to each, instead of the whole time to one. A single plate that has been thus exposed to several negatives yields what is called a *composite*. The paper is illustrated with a number of these composite pictures, which are of very great interest. The result, however, of this inquiry lends no countenance to the belief that any special type of face predominates among phthisical patients, nor to the generally entertained opinion that the narrow, ovoid, or "tubercular" face is more common in phthisis than among other diseases. The conclusions arrived at are, therefore, negative, but, as the author remarks, it may be that they are no less valuable, as they at least succeed in refuting a commonly accepted error.

In conclusion, we may state that this volume of Reports will well repay perusal, and is worthy of the reputation of the staff of Guy's.

AN INDEX OF SURGERY. (a)

In the preface to this work we are told that the "Index" is intended to be used by the senior student, shortly before he presents himself for his final examination, and after he has carefully studied a complete text-book of surgery. If we could feel certain that the book would be used in this way only, we would not have anything to say against it; but we greatly fear that for the one student who will make use of it in this way there may be hundreds who will use it simply with a view to hurriedly cramming themselves for examination purposes with a mass of undigested facts, to the exclusion of a sound knowledge of the principles of surgery, and who will, consequently, neglect the larger text-books, by the study of which alone they can become reliable practitioners.

We are told that the work is a complete collection of facts, suited to take the place of the notes which the

student usually makes for himself; and which, according to Mr. Keetley, "being made with unripe knowledge, and consequently with the bad judgment which such immaturity implies," are often necessarily thrown aside as useless. But, on the other hand, every experienced teacher knows that the value of note-taking consists mainly, if not entirely, in the effort made by the student to generalise and mentally digest the mass of facts which have come under his observation; and that, unquestionably, the value of the notes for subsequent reference is merely of secondary importance.

Although this industrious compilation contains a great deal of really valuable information on surgical matters, yet errors of a grave nature are easily to be discovered in it. We may point, for example, to the treatment recommended for the relief of that serious surgical condition produced by stricture. No student could possibly be benefited by being directed to transform a bulbous bougie into a filiform one by the simple process of "snipping off" the bulb. Again, the treatment by trocar and canula of compound palmar ganglion will not recommend itself to experienced surgeons, who are familiar with the dangers that attend operative interference with this disease.

On the whole, we cannot but regret that such an amount of labour should have been expended on a work which we cannot but feel will be as much a source of detriment as of advantage to the student for whose benefit it is intended.

PASS LISTS.

Royal College of Surgeons of England.—The following candidates having passed the required examination for the diploma, were admitted Members of the College on Monday, November 13th:—

Atkins, George, L.R.C.P. Lond.
Baker, William Brain, L.S.A.
Bozal, Robert, L.R.C.P.
Bromley, Henry Urgent.
Butterworth, Samuel, L.R.C.P. Ed.
Coombe, Charles Frederick.
Furnival, Francis Henry, L.S.A.
Heathcote, Ralph G., L.R.C.P. Ed.
Herman, Christian L., M.B. Ed.

Lister, Joseph Herbert, L.S.A.
Littlewood, John Osceott, L.S.A.
Priestley, John, L.S.A.
Shirley, Matthew B., L.R.C.P. Ed.
Smith, W. A. Winwood, L.S.A.
Statham, Reginald W., L.S.A.
Waring, John Arkle, L.R.C.P. Ed.
Wilson, George, M.B. Ed.
Wyborn, Samuel, L.S.A.

The following were admitted on Tuesday, Nov. 14th:—

Aslanian, Bedros, L.S.A.
Banham, William Wilfred.
Beasley, William C., M.B. Dub.
Bown, Arthur Thomas.
Dacre, John.
Dale, Walter F., L.R.C.P. Lond.
Guinness, Thomas Archibald.
Harriss, Henry Jones.
Hall, Alfred.
Hind, Wheelton.
Hoar, O. de Sambler.

Horrocks, William Henry.
Maye, John, L.S.A.
Myles, James P., L.R.C.P. Lond.
Porter, Guy David.
Price, Thomas William.
Satter, George H., L.R.C.P. Ed.
Sells, Hubert Thomas.
Smith, J. E., L.S.A.
Sunderland, Septimus.
Winder, William Henry.

The following were admitted on Wednesday, Nov. 15th:—

Bailey, Charles Frederic.
Caiger, Frederic Foord.
Cardwell, Thomas.
Crick, William T., L.R.C.P. Lond.
Cuff, Robert.
Dakin, William Radford.
Davis, John Warren, L.S.A.
Dun, Walter A., L.R.C.P. Lond.
Ellison, William Augustine.
Fraser, James Alexander.

Harrison, John, L.R.C.P. Ed.
Hodges, Herbert Chamney.
Jennings, William Munro.
Kinch, George H., L.R.C.P. Ed.
Leon, Greville Ewing, L.S.A.
Masters, Edgar Ernest.
Mead, Herbert R., L.R.C.P. Ed.
Smith, Howard Lyon.
Tallier, George Arthur.
Woodhouse, Alfred E. Clayton.

Royal College of Surgeons, Edinburgh.—During the October sittings of the Examiners, Mr. Joseph Henry Zepeto, Trinidad, passed his first professional examination, and the following gentlemen passed their final examination, and were admitted Licentiates of the College:—

Schmidt, Alfred E., London.
Kirkham, F. W., Tilney, Norfolk.
Fletcher, Howard B., Lincoln.
Robertson, John M., Galston.
Wilson, William, Edinburgh.

Logan, John, Milngavie.
Gettings, John S., Staffordshire.
Snell, W. S., Stonehouse, Devon.
Hutchinson, Creighton, Kilrea.
Clark, John Robert, Coburg.

William Thomas Elliott, Diss, passed his first professional examination for the Licence in Dental Surgery of the College; and the following gentlemen passed their final examination, and were admitted L.D.S.:—

Thomson, Joseph S., Dublin.
Furdie, Hume, Alford.
Blandy, Henry, Chesterfield.

(a) "An Index of Surgery." By O. B. Keetley, F.R.C.S. London: Smith and Elder. 1882.

Notices to Correspondents.

THE CHARGE OF MANSLAUGHTER AGAINST AN ASYLUM OFFICER.—In our last we expressed regret at the announcement made in the public press of the committal of a former medical officer of the Gloucester Lunatic Asylum on a charge of manslaughter by violence on a patient. We are happy on unimpeachable authority to announce that our contemporaries were misinformed, and that the person so charged was a former male attendant at the Asylum, not medical officer, as reported.

ANXIOUS.—We cannot be of any assistance to you in the matter.

MR. SCOTT (Cornwall).—Mr. Sampson Gamgee's address, entitled "What has Vivisection done for Human Surgery?" will give you exactly the information you require. It is published, price sixpence, by Messrs. Churchill. Prof. Owen's recently published "Experimental Physiology" (Longmans) is a crushing refutation of the miserable pretensions of the anti-vivisectionists. In this country the law enacts that any scientific inquirer desiring to resort to experimental proof of physiological problems shall obtain a licence to do so from the Secretary of State. Such licences are, as a rule, refused, and thus the study of experimental physiology is "boy-cotted." In other countries scientific men are not insulted in this way, but research is encouraged, with the result that the lead once taken by England is being usurped by Germany and France. There is no vivisection society, but recently an "Association for the Advancement of Medicine by Research" was formed in London, with the object of teaching the public how they are being imposed upon by the mercenary pretensions of self-styled humanitarians.

POSTERIOR THORACIC.—Your information is not at all correct. You will find the facts accurately detailed in the *Medical Press* for July 17.

AMBIDEXTER.—No. It was Mr. Charles Reade who raised the discussion. The novelist who is ill is Mr. Anthony Trollope.

GNORRHOEAL COMPLICATIONS.

J. W. D. writes: A patient of mine, who suffered from gonorrhoea some ten years ago, complains now of scrotum sweating after going to bed, with darting pains in part (the pains are only very slight, something like what he calls prickling). Could you advise me as to treatment? I have had him on pot. iodid. and tonics for a month or so without any change for the better.

[The data given by J. W. D. are rather meagre, but it seems most likely that the symptoms depend on some defective innervation of the region affected—probably vaso-motor in character. We think a judicious course of arsenic, with the local use of some weak belladonna ointment, would meet the requirements of the case as it is described.—ED.]

A POLITE HINT FOR CONTEMPORARIES.—The *Deutsche Med. Zeitung* (Nov. 9th) prints in "big" type the following paragraph:—"We most respectfully request those esteemed editors who use or reprint verbatim our original reports or excerpts, always to mention the *Deutsche Med. Zeitung* as the source whence they are taken."

MR. S. WILSON (Liverpool) should write to the Secretary for information. We believe election is merely a formality if proposed and seconded by two members.

LIEBIG'S EXTRACT OF MEAT.—The somewhat protracted suit of the Liebig's Extract of Meat Company v. Anderson, for an alleged invasion and colourable imitation of their labels and rights, has been decided in favour of the defendant. Dr. Pettenkofer, who gave evidence in the case, stated that the prepared extract of meat was first invented by a French chemist, Proust, in the year 1801, and, therefore, Liebig was not the real inventor of what is sold under his name as "Extract of Meat."

MR. C. B. (Dublin).—It is necessary to have a personal interview with the head of the department, and this is not easy to obtain. We will, however, represent the case in the proper quarter and see what can be done for you.

CERTIFICATES IN SANITARY SCIENCE.

ARRANGEMENTS have now been made by the King and Queen's College of Physicians for granting a certificate in sanitary science to Licentiates in Medicine of the College. The first examination will take place in January, 1883, in the following subjects:—1. Engineering—including hospital and house construction, sewage, drainage, ventilation, water supply; 2. Law—the Acts relating to public health, duties of health officers; 3. Etiology and Prevention of Diseases—epidemiology, contagion, infection, hereditary influence, accommodation and conveyance of the sick, management of hospitals; 4. Chemistry—air, water, food; 5. Meteorology and Climatology, and Vital Statistics.

WAKEFIELD.—Thanks for the information; the mistake was an unfortunate one on the part of the newspaper press; not an unusual occurrence when they essay matters medical.

DR. C. THEODORE WILLIAMS will deliver a lecture at the Brompton Consumption Hospital to-day, at 4 p.m., "On Phthisis with Emphysema." Members of the profession will be admitted on presentation of their cards.

DR. R. N. (Hampstead).—The matter has not been forgotten; it is simply waiting its turn with other reviews.

THE UTILITY OF DRUNKENNESS.

MR. MATHIEU WILLIAMS writes in the *Popular Science Review* on this subject, holding that drunkenness is not an unmixed evil, but from a Darwinian point of view is really an important factor in the development of the species. He argues "that the survival of the coarser, more brutal, and purely animal specimens of the human race is prejudicial to its present interests and future progress. They must consequently be removed so as to permit the survival and multiplication of the more intellectual and refined specimens. This happy result is accomplished by the spontaneous self-extinction of the coarser specimens in a manner presumably pleasant to themselves by

means of the immoderate use of intoxicating liquors." This is truly a happy way of looking at the subject. By an extension of the same principle we may come to congratulate ourselves on typhoid, phthisis, gout, &c., as beneficent means of clearing out all the dirty, delicate, and gluttonous population.

MEETINGS OF THE SOCIETIES.

CLINICAL SOCIETY OF LONDON.—Friday, Nov. 24th, at 8.30 p.m., Dr. Cavay, "On two Cases of Symmetrical Congestive Mottling of the Skin" (patients will be shown).—Mr. J. E. Adams, "On a Case of Lumbar Nephrectomy for Carcinoma."—Mr. R. J. Godlee, "On Two Cases of Intussusception in Infants treated by Abdominal Section."—Dr. Dyce Duckworth, "On Two Cases of Subcutaneous Rheumatismal Nodes" (one of the cases will be exhibited).

HARVEIAN SOCIETY OF LONDON.—Thursday, Nov. 23rd, at 8.30 p.m., the first of the Harveian Lectures, "On Ophthalmic Medicine and Surgery in relation to General Practice," by Henry Power, M.R.C.S.

Vacancies.

Dewsbury Infirmary.—House Surgeon. Salary, £80, with board and lodging. Applications to be sent to the Secretary not later than Nov. 29th.

Dundalk Union, Carlingford Dispensary.—Medical Officer. Salary, £100, and £25 as Medical Officer of Health. Election, Nov. 25th.

Galway Union, Arran Island Dispensary.—Medical Officer. Salary, £10, and £15 as Medical Officer of Health. Election, Dec. 1st.

Kingston Union.—Medical Officer. Salary, £80. Applications to be sent to the Clerk on or before Dec. 4th.

Seamen's Hospital (late "Dreadnought"), Greenwich.—Matron. Salary commencing at £80, with board and lodging. Applications to be forwarded to the Secretary on or before Nov. 27th.

Wolverhampton and Staffordshire General Hospital, Wolverhampton.—House Physician. Salary, £100, with board, &c. Also House Surgeon. Salary, £170, with board, &c. Applications to be addressed to the Chairman of the Medical Committee not later than Dec. 4th.

Appointments.

BARR, T. M.D., C.M., F.F.P.S. Glas., Aural Surgeon to the Sick Children's Hospital, Glasgow.

CAMPBELL, W., M.B., C.M., House Surgeon to the Royal Infirmary, Glasgow.

COATS, J., M.D., F.F.P.S. Glas., Pathologist to the Sick Children's Hospital, Glasgow.

DAVIDSON, J. H., M.B., C.M. Ed., House Surgeon to the Royal Infirmary, Glasgow.

FINLAYSON, J., M.D., F.F.P.S. Glas., L.R.C.S. Ed., Physician to the Sick Children's Hospital, Glasgow.

FORBETH, E., M.D., M.Ch. Glas., Medical Officer for the Birral District of the Dewsbury Union.

GELLATLY, A., M.B., M.Ch. Ed., Medical Officer for the First District of the Ashton-under-Lyne Union.

HUDSON, E., M.R.C.S., Junior Assistant House Surgeon to the Sheffield Public Hospital and Dispensary.

LAWRIE, W. J., M.B., C.M., House Surgeon to the Royal Infirmary, Glasgow.

MCNIVEN, E. O., M.B., C.M. Ed., House Physician to the Royal Infirmary, Glasgow.

NEWMAN, D., M.B., C.M., F.F.P.S. Glas., Extra Dispensary Surgeon to the Western Infirmary, Glasgow.

REID, T., M.D., F.F.P.S. Glas., Ophthalmic Surgeon to the Sick Children's Hospital, Glasgow.

RICH, A. C., M.B. Lond., M.R.C.S., Pathologist to the Liverpool Royal Infirmary.

SEMPLE, A., M.B., C.M., House Physician to the Royal Infirmary, Glasgow.

WILLOOCS, F., M.D. Lond., M.R.C.P. & M.R.C.S., Assistant Physician to Charing Cross Hospital.

YOUNG, C. S., L.F.P.S. Glas., Assistant Medical Officer to the Barnhill Hospital, Glasgow.

Births.

HARTE.—Nov. 17th, at 30 Athenum Street, Plymouth, the wife of Fleet Surgeon M. A. Harte, R.N., of a son.

HILL.—Nov. 17th, at 55 Wimpole Street, London, W., the wife of Berkeley Hill, F.R.C.S., of a son.

KIDD.—Nov. 15th, at 12 Montpelier Row, Blackheath, the wife of Walter Kidd, M.D., of a daughter.

LONGMORE.—Nov. 14th, at Woolston, Hants, the wife of Surgeon-General T. Longmore, C.B., of a son.

Marriages.

ADAMS—WILLIAMS.—Nov. 16th, at St. Mark's Church, Lyncombe, Bath, Henry Adams, M.R.C.P.E., of Greenwich, to Fanny Garrigues, granddaughter of the late Venerable Archdeacon Williams, D.D., of Jamaica.

DALY—VON DONOP.—Nov. 16th, at St. Andrew's Church, Bath, Edward Owen Daly, M.A., M.B. Oxon., eldest son of Dr. Owen Daly, F.R.C.P., Hull, to Alice Brenton, youngest daughter of Vice-Admiral R. P. Brenton von Donop, Bath.

Deaths.

BRICKWELL.—Nov. 9th, at Somersham, Hunts, Henry Brickwell, M.B.C.S., aged 66.

CRISP.—Nov. 15th, suddenly, Edwards Crisp, M.D., of 16 Beaufort Street, Chelsea, aged 78.

GULLIVER.—Nov. 17th, at Canterbury, George Gulliver, F.R.C.S. and F.R.S., formerly Surgeon Royal Horse Guards (Bde), and Hunterian Professor at the Royal College of Surgeons, aged 78.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.
Surgeon to the London Hospital.

(Continued from page 436.)

A QUESTION arises in regard to the powers of locomotion exhibited in these cases, whether the bladder was ruptured through all the coats at the time of the injury, or whether a partial rupture became complete some hours or days afterwards. Dr. Andrew Dewar, of Dunfermline, (a) has narrated a case in which it is probable that the bladder received some damage during a scuffle, and gave way the next day, at the time of a fall, and, perhaps, in consequence of it. William Niblo, 27, received some blows in a drunken brawl. He assisted in unloading a vessel for an hour without complaining of any injury. He staggered home at midnight, and went to bed. He rose in the morning, twice drank spirits, and was seen wandering about in a state of apparent intoxication. About mid-day he fell on smooth ground, and could not get up without assistance. He was carried home and put to bed, and never rose again. Dr. Dewar thinks that the bladder was not ruptured in the scuffle, but when the patient fell, and in this view I entirely concur. The occasional occurrence of ruptures involving only the mucous and muscular coats is shown by the appearances in Gruber's case (b). In addition to a complete intra-peritoneal rupture an inch and a-half long, there was a second tear lower down, involving only the mucous and muscular tissues. Another explanation has been offered to account for Dr. Harrison's case. At the post-mortem the recto-vesical *cul de sac* was seen to be shut off from the general cavity of the peritonæum by adhesions between the lower intestines and the bladder, and contained a quart of colourless urine. It has been conjectured

that the retention of the urine in the *cul de sac* would not be attended with the same immediate disturbance to the system as its diffusion through the general peritoneal cavity. This explanation, though possible, does not appear to me to be so probable as the occurrence at first of a partial rupture, afterwards becoming complete. Dr. Max Bartels alludes to the latter method of explanation, and appears to lean towards it. In Dr. Harrison's and Dr. Gillespie's cases I believe that the peritonæum did not give way for two or three days after the injuries, and that in Mr. Crossley's case the interval was much longer. As soon as the shock, pain, and peculiar feelings occasioned by a ruptured bladder have subsided, the subject of the injury, who had previously felt an urgent call to void urine, and may have been on his way to satisfy the call, experiences, perhaps, a temporary feeling of relief. Very soon, however, he begins to be tormented with a strong and frequent desire to make water. On attempting to do so, nothing comes away; but straining may cause a few drops of blood or bloody urine to issue from the urethra. Accompanying this distressing condition, pain will be felt in the hypogastric region, or there may be constant acute pain at the umbilicus, or all over the body, the pain being intolerable in the erect position. Pallor and anxiety of countenance, restlessness, thirst, difficulty in movement, nausea and vomiting, depression, and feeble pulse will be the evidences of grave constitutional disturbance. In this condition the patient is seen by his medical attendant, who introduces a catheter, and draws off blood, or a variable quantity of blood and urine combined, or fails to remove anything at all. The desire to micturate may not be relieved by the catheter. If the patient is not the subject of stricture, or of fracture or displacement of the pelvic bones interfering with the urethra, the catheter will pass readily enough into the empty and more or less contracted or collapsed bladder. Separation of the innominate bones at the symphysis may cause a deflection of the catheter to one or the other side. Having entered the bladder, the point of the catheter may impinge against a sound part of the viscus, and then it will be found difficult to rotate the instrument, and to depress it between the patient's thighs, but, if the rent be on the posterior wall, on withdrawing

(a) *Edinburgh Medical and Surgical Journal*, 1829.

(b). Quoted in Dr. Thorpe's paper, *Dublin Quarterly Journal*, vol. xiv., page 813. Reference given to *Dub. Hosp. Gaz.*, vol. v., page 263.

the catheter a little and altering its direction, it may suddenly slip through the rent into the peritoneal cavity, become freely movable, and withdraw, probably, a large quantity of fluid in place of the small quantity of blood, or the few ounces of blood and urine previously removed. When the rent in the bladder is large, the end of the catheter will most likely at once pass through it, entering the urethra up to the hilt, and drawing off a large quantity of bloody urine, mixed, perhaps, with serous fluid from the peritonæum. Mr. Poland's case is instructive on this point. Two days after the accident, five ounces of bloody urine were drawn off by Mr. Poland, but six hours later Mr. Durham removed with the catheter three quarts of bloody urine, and evidently from the abdominal cavity. So, also, in Mr. Cusack's first case. The catheter, when introduced on the second day, drew no water, but, on altering its direction with the finger in the rectum, three pints issued. In Fergusson's case, a very small quantity of bloody urine was drawn off, but shortly afterwards about 102 ounces. The amount of blood mixed with the urine is also variable. Occasionally pure blood passes, or blood-clot speedily blocks up the eyes of the catheter. Rarely the urine, though scanty, is clear. The quantity of blood in the urine diminishes steadily, and the urine will become clear by the second or third day, or, at most, be of a dull brownish red colour, or have the appearance of coffee-grounds. The quantity of urine drawn on occasions subsequent to the first introduction will vary, according to the frequency of catheterising and the position of the extremity of the instrument. A catheter confined to the cavity of a ruptured bladder will not remove more than a few ounces of urine—rarely, I think, more than four or six at the most; but whenever it traverses the rent, half-a-pint to thirty ounces, and even more fluid, may be expected to issue. The character of the stream issuing from the catheter is important. As the contraction of the muscular coats of the bladder no longer assists the flow, and as the abdominal muscles will probably be exerted only for the purposes of respiration, the urine will either well out gradually, and run down by the side of the catheter, come out almost *guttatim*, or pass from the instrument in an intermittent stream during the periods of expiration. It may be necessary for the medical attendant to compress the abdomen before he obtains any urine, but compression does not always assist the flow. As a general rule, the patient from the first is unable to pass water, and continues to display this inability to the end. In a few cases water has been passed voluntarily by the patient, either at the outset, or at some period during the progress of the case. Mr. Hiley's patient passed water several times in a stream at 5 a.m. on the third day, and at 10 a.m. made water, which ran down to his knees. This was accompanied by an evident improvement in the patient's condition. The pain abated, pressure on the abdomen could be borne, and he could turn over in bed without pain; vomiting ceased, his spirits revived, and a little later he voided three ounces of urine. The next day he relapsed, and speedily sank. One of Mr. Ellis's patients passed a little water on the second and third day. One of Dr. Ramsbotham's patients passed a small quantity of urine on the second day. Dr. Lente's patient, a lad of 18, is said to have discharged urine two feet from the meatus on the second day. Mr. Drake's patient passed water on the third day, and Mr. Bower's patient passed one and a half ounces of water voluntarily on the second day. On the first day Mr. Wathen's patient got on a night chair and passed one ounce of bloody urine, and on the ninth day while at stool he passed some ounces in a regular stream. In Mr. Le Gros Clerk's case on the sixth day, and in my second case on the fourth day, the patient rallied and passed water freely himself. In Mr. Hird's case two or three tablespoonfuls of urine dribbled away on the evening of the accident. All the foregoing were intra-peritoneal ruptures. A few of the patients with extra-peritoneal ruptures passed some blood when trying to make water, one passed a spoonful of urine, another half a pint

on the second day; a female passed a small quantity mixed with blood, whilst half a pint dribbled away, and in the course of her illness, she voluntarily passed urine more than once; another patient is said to have made water on the second day with tolerable freedom. In my fourth case, where the rupture was situated just above the prostate, there was at first *incontinence of urine*, and in a recent case of idiopathic rupture behind the prostate, brought before the Hunterian Society by Mr. Tay, urine seems to have dribbled rather freely from the urethra. In Dr. Kneeland's case the patient, on the third day, passed water standing with his feet on the floor, his hips resting against the edge of the bed, his body leaning forward, and his hands pressed on the abdomen. Drawing in a full breath and bearing down forcibly urine started in a full stream. When he expired the stream would stop, and on making a full inspiration would again start in a full stream. He complained of it hurting him over the bowels and being very hard work.

The primary symptoms which have been enumerated, pain in the abdomen, a feeling of something having given way within that cavity, difficulty in standing and walking, a certain amount of shock or depression, temporary relief to the desire to make water followed by a more urgent desire but inability to do so, and the results of catheterism in bringing away blood or bloody urine, or nothing whatever, are common both to the intra- and extra-peritoneal ruptures. Here, however, the two classes of cases diverge from each other. In the intra-peritoneal ruptures the symptoms are decidedly more severe. The shock at first is greater, and the symptoms of peritonitis, as a rule, set in within a few hours and increase in severity. A surgeon called to a case of the kind, having noted the history, will at once proceed to an examination of the patient's abdomen. Only in a severe injury or one occasioned by great force and accompanied by other lesions is he likely to observe any external mark of violence. "No sign of external injury" is a frequent note. But he will find most probably that the abdomen is swollen or prominent in front, tender on the slightest pressure, and tympanitic, but in the hypogastric region for a variable distance, and sometimes extending toward one or both of the iliac fossæ, the percussion note is likely to be dull, more especially in the erect position. There may even be a more or less defined swelling resembling the bladder between the umbilicus and the pubes, due, I believe, to the circumstance that the urine is temporarily confined by the disposition of the coils of intestine. A tumour of this kind was noticed in the case under Mr. Spence, who brings forward several arguments to show that the tumour was really formed by the bladder itself, distended with urine which had been confined accidentally within the organ owing to the peculiar character of the rent, and to temporary adhesion or occlusion of its edges. That the urine was really outside the bladder is proved, I think, by the details of other cases in which a swelling of the kind has been noticed. In Dr. Ramsbotham's second case of rupture in a woman in labour, it is stated that no vesical tumour was perceptible, but an irregularity was observed on the uterine tumour like a bent knee or elbow. In Mr. Partridge's case, which was complicated with stricture, there was a tumour in the region of the bladder, and, under chloroform, twelve ounces of urine were drawn off. Mr. Partridge was sent for on the second day after the admission of the patient because the house-surgeon could not pass the catheter. He cut into the bladder and found it empty, and observed that the catheter had evidently been passed through the rent. In a female under Mr. Stokes there was a large circumscribed tumour, very much resembling the gravid uterus, and very dull on percussion, filling the hypogastrium, and extending upwards to within an inch of the umbilicus. The woman had not passed water since the receipt of the accident; yet, when the catheter was introduced it drew off only one ounce of urine, slightly tinged with blood, which trickled slowly through the catheter. The tumour increased in size, and

was larger the next day, but on the third day it is noted that the tumour was larger, but no longer circumscribed, showing that the urine was gradually becoming diffused.

In the case under Mr. Heath, who made a very careful examination of the abdomen, the following particulars were observed:—"The abdomen is prominent in front; no bulging in the flanks; it is firm and tense to the feel, and very painful on the slightest pressure, notably over the hypogastrium. There is dulness above the pubes to a point midway between the pubes and umbilicus. The left flank is dull on percussion; the right resonant. There is no bruising of the back, but there is tenderness in the left lumbar region." The dulness was evidently the result of the effused urine, for directly an incision was made through the anterior abdominal wall a gush of urine followed. Examination per rectum will elicit tenderness and pain, and in some cases the finger may be able to detect a collection of fluid in the recto-vesical *cul de sac*. I could not feel this in either of my own cases, and Mr. Spence, whose attention was particularly directed to this point, found, at the post-mortem, that a little turbid urinous fluid, and some folds of small intestine occupied the inferior *cul de sac* of the peritoneum, but no fluctuation or distension could be detected, on examination with the finger, in the rectum.

In Mr. Hird's case the collection was readily demonstrated. The abdomen of the patient was distended, but did not evince the circumscribed form observable in cases of distended bladder from retention. A full-sized catheter was introduced, and withdrew two or three tablespoonfuls of water only. The bladder was contracted, and greatly opposed the moving of the catheter. On examination per rectum Mr. Hird could distinctly feel a swelling between the bladder and intestine, yielding to pressure, and returning to its original size.

In a typical case of intra-peritoneal rupture the patient will exhibit all the symptoms of peritonitis, in addition to those proper to the lesion itself. He will lie in bed, with his knees drawn up, or be propped up with pillows, to relax the abdominal muscles. He will have a pinched, anxious, haggard expression of countenance, look pale and anæmic, and be tormented with a frequent or constant desire to pass water, leading him to make ineffectual efforts to empty his bladder. He will suffer from thirst, and sooner or later be troubled with vomiting, bringing up a greenish yellow fluid, and even the water which he had drunk copiously to quench his thirst. Vomiting is sometimes present at the outset, sometimes sets in on the second day, or appears towards the termination of the case. Usually it increases in urgency, from its appearance till death ensues. With vomiting, hiccup is frequently associated. The pulse will be small, feeble, and rapid, ranging between 90 and 130 degrees. The temperature will probably be a little over the normal. The respirations will be hurried, accompanied, perhaps, by dyspnoea, or a feeling of oppression at the chest. The abdomen will be tense, tender, tympanitic above, dull, and possibly fluctuating below. The tongue will be furred and dry, and the bowels confined. Occasionally there may be rolling of the intestines and distressing tenesmus. Purgative medicines will probably produce foetid stools, and enemata may give exit to flatus, occasioning relief to the feeling of distension of the belly. Unless stupefied with alcohol, the patient may be expected to pass the first night after the injury in much torture, vainly endeavouring to obtain rest and sleep. Throughout the illness there will be marked restlessness and insomnia. As the case proceeds, the symptoms become aggravated, the swelling and tension of the abdomen increase; clammy sweats appear on the skin; the hiccup and vomiting become more urgent and distressing; the pain is intolerable; the countenance sunken and ghastly; and the patient may sink into a state of collapse, or into a typhoid condition, attended with delirium and coma. Not infrequently, after a few days, especially about the fifth or sixth, if the patient survive so long, there are marked signs of amendment. Nature has commenced the repair of the rent in the

bladder, and the edges of the rent have become agglutinated, or blocked by the sigmoid flexure, or a coil of small intestine. The patient passes water voluntarily, takes food without rejecting it, sits up in bed, is free from pain, and comparatively cheerful. An error in diet, or a purgative acting on the bowel, or the course of the disease itself, dispels the deceitful improvement; the former symptoms recur, and the patient may expire on the very day which follows the signs of hopefulness and recovery. In one or two cases, stercoraceous vomiting has occurred; and in a case at St. Bartholomew's Hospital, a coil of intestine entered the rent in the bladder, and gave rise to symptoms of intestinal obstruction which masked the symptoms of rupture of the bladder.

(To be continued.)

TREATMENT OF NEURALGIA. (a)

By CHARLES R. FRANCIS, M.B. Lond., &c., &c.,
Formerly Professor of Medicine in the Medical College, Calcutta.

My object in the present paper is to give a sketch of the treatment which, in common with many others, I have found beneficial in the management of idiopathic neuralgia, and of neuralgia which, of traumatic birth, has become persistent from habit after removal of the original cause. No new remedy is proposed, but I venture to suggest, in addition to other suitable treatment, the value of combining those that are already in use, giving them in sufficiently large doses, and at particular times.

It is not necessary to say much on the pathology of neuralgia. Gentlemen present are quite as familiar as myself—some even more so—with the work and writings of those who have told us all that is yet known (practically nothing) on the subject. Sir C. Bell, Rowland, Downing, Anstie, Chapman, Latham, Liveing, &c., in England; Eulenberg, Romberg and others in Germany; and Charcot, &c., in France, are names well known in connection with neuralgia and other diseases of the nervous system. The most exhaustive account, perhaps, of the disorder is to be found in the eleventh volume of Ziemssen's "Cyclopædia of Medicine." What may be the exact condition of the nerve in neuralgia is not known with certainty. Post-mortem examinations of persons who—victims to it during many years of life—have eventually died of something else, reveal nothing. The pain, variously described as boring, burning, plunging, shooting, crushing, cutting, dragging, a feeling as if the nerve were being drawn through a narrow ring, &c., may have been most agonizing; but no sign is left. Dr. Woakes says, that there is effusion of liquor sanguinis from arterioles in the track of the nerve affected, and that the sentient nerve fibrillæ are compressed by it. Doubtless there are such cases; and ergot of rye, which Dr. Woakes recommends, by restoring the vaso-motor function—the suspension of which had allowed the effusion to take place—acts beneficially. But this can hardly be the pathology in every case of neuralgia. Vascular spasm is the more probable condition. Considering that the disorder is, in those who are subject to it, most rife in cold, damp weather, we may, I think, fairly infer that the nerve is—so to speak—limp, irritable, and readily worried by the spasm of vessels which lie in its course. An old lady of 80, who had been a martyr for sixteen years to sciatica which had made her quite lame, thus expressed herself to me after taking one or two full doses of an anodyne antispasmodic and nervine tonic:—"Look, I am not a bit lame, now; the leg feels so much tighter. See, I can kick it out, and feel no pain!" and she kicked with vigour. The anodyne had unlocked the spasm, whilst the tonic gave temporary vigour to the nerve. Doubtless, there was more than

(a) Read before the Harveian Society of London, Nov. 16th, 1882.

mere spasm in this case, though it was a prominent feature.

Although in the practice of medicine a physician is guided by certain general rules which are applicable to the various classes of diseases, he finds by experience—with reference to the deranging influence of idiosyncrasies, &c.—each disease requires to be specially studied and dealt with on its own merits. True as this is of disease in general, it is especially so of neuralgia. Once started, the pathology of the disorder is probably the same in most cases; but not so the cause that started it. Now, it is cold; now, warmth; now, some local irritation which is tangible and capable of removal; now, the mischief is deep-seated, and either beyond our ken or removable with great difficulty. Uterine derangements are constantly associated with neuralgia—now as a cause, now as a consequence. The *fons et origo* of an attack is as often mental as physical; and frequently there is no apparent cause at all.

For the successful management of some forms of neuralgia there are two paramount requisites—*time* and *patience*. No true physician will be content with merely relieving the pain which, in chronic cases, will assuredly return again and again with unabated, and often with increasing, vigour.

There is almost always something preventively wrong in the *habits* of patients so afflicted, or in circumstances beyond their immediate control. So little importance, however, do patients attach to these circumstances, even if they be aware of their existence, that it is often only by patient investigation, which necessarily occupies more time than busy men have at their disposal, that the fact is elicited; but its elucidation makes all the difference to the patient. The outcome of a nervous temperament—the nervous constitution involving a proneness to neurotic disorders—that cannot be altered. But the condition, which enables the neuralgia to acquire a more powerful hold of its victim, may frequently be removed or ameliorated; so that the opportunities hitherto enjoyed by the disorder for effecting an invasion may become reduced to a minimum.

In the general treatment of neuralgia there are certain principal indications, one or other, or all, of which need to be fulfilled—viz., to eliminate, to soothe, and to strengthen. Besides these there is another more difficult of fulfilment—breaking through the habitual recurrence of the pain. In some cases elimination alone will effect a cure, as with decayed teeth, worms, or an over-loaded colon; in others—the nervous system being unusually irritable—soothing remedies suffice, as the hypodermic injection of morphia; in others, and these are the most intractable, a combination of remedial measures is required. In these last cases elimination, soothing, strengthening, and habit-breaking must frequently, more or less, all be had recourse to. The three first are the principles that guide the rational practitioner of hydropathy which, in the hands of such an one, becomes so valuable an adjunct to the medical armamentarium in the treatment of nervous exhaustion, amongst the victims of which neuralgia so frequently appears. Without taking up the time of the Society with any more prefatory remarks, I will now proceed to give the outline of a few cases in illustration of them.

Of the cases which come under the two first heads it is not necessary to say much. Neuralgia depending upon a decayed tooth disappears with removal of the offender, though too many teeth, alas! have been removed as supposed originators of the neuralgic pain, when they have had nothing whatever to do with it. The pain that is felt in a particular spot is sometimes so intense that malignant disease is suspected. And herein occasionally exists a difficulty in diagnosis. We now know that the pain of neuralgia may be quite as intense as that of malignant disease; and it is not always easy to decide which is which. Some who are present this evening may remember a case where, for supposed malignant disease, a kidney was extirpated.

The operator, holding up the organ before the vast assemblage of spectators, said: "Gentlemen, I am bound to admit that I never saw a healthier kidney."

Mr. M., a merchant in Calcutta, suffered intense pain over the centre of the middle portion of the left serratus magnus muscle. The pain was more or less intermittent, and the patient had been exposed to malarial influences. Nothing could be felt; there was no pain on pressure, nor any indications, personal or otherwise, of malignant disease. And, so, neuralgia of malarious origin was diagnosed, and he was treated accordingly. Six months afterwards, coming to England for further treatment, Mr. M. died of melanotic sarcoma affecting the part of the muscle before mentioned.

A married lady in India, subject to occasional attacks of neuralgia, was treated for severe pain affecting the right side over the hepatic region, and the whole of the right arm from the shoulder to the tips of the fingers. There was no increase of pain on pressing over the liver, nor any special indication, except one—of hepatic abscess; and yet the lady died (I believe, there was no post-mortem) of this disease opening into the lungs. The single indication was acute lancinating pain in the right hypochondrium; and it was most intense, the patient throwing herself on the floor in her agony. Had this acute pain occurred *suddenly*, as we sometimes see in the course of an attack of hepatitis, it would have been recognised at once as probably indicative of supuration. As it was, the case was diagnosed as one of neuralgia.

In cases under the second head, where there are no complications, and where a few hypodermic injections permanently relieve the patient, the disorder is probably not of long-standing, and without periodicity. In those that are more chronic it is necessary to continue the anodyne. The pain then returns after a time with regularity; and finally the case degenerates into the third category. Doubtless it has often become a question of anodyne or neuralgia. And in this way many, I believe, have taken permanently to opium.

I proceed to give illustrations of cases under the third head.

When living in Surrey in 1878, I was hurriedly summoned, one Sunday afternoon, to see my neighbour, Mr. A., who was said to be in a fit. I found him lying on his back quite unconscious, with a composed but death-like aspect. There were no convulsions, no lateralism, no foaming at the mouth, nothing beyond stertorous breathing indicative of—as supposed by the family—an apoplectic seizure. In truth, he was narcotized from having taken a variety of intoxicating drinks, with which he had endeavoured—only too successfully—to combat a severe attack of neuralgic pain. He had inhaled chloroform besides. Mr. A. had been a martyr to neuralgia for thirty years. Originating in an accident to his face, it for several years located itself in (I presume from the description) the facial branches of the superior maxillary nerve. It then left the face and settled in the abdomen, where it steadily remained till some eight or ten years previous to the time of my seeing him. Then, altogether leaving the abdomen, it reverted to the face, attacking not only the old locality, but worked its way round by the cervico-facial nerves to the back of the neck, which would be held during the paroxysm as if in a vice. Sometimes the heart would feel at that time as if it were turned upside down, and it would apparently cease to beat altogether. When the paroxysm was over, the pulsations would recommence with a strong thump. Some very curious symptoms witnessed by Sir C. Bell are recorded in his book, as illustrations of the effects of the nervous irritability which is found to so great an extent in the victims of neuralgia. In one, the patient saw all sorts of images, heard all sorts of noises, and vomited, in imagination, all sorts of creatures. In another, the patient would through sheer nervousness swallow a huge morsel, as an egg, entire, declaring that during

mastication it would suddenly go down ; nothing could stop it ! Niemeyer mentions the case of a gentleman who always had an attack of neuralgia with the first mouthful at a meal. Unwilling, of course, to lose his breakfast or dinner, or whatever the meal might be, he would munch a crust beforehand, and so get over the attack in good time ! The attacks in Mr. A.'s case usually commenced soon after midnight, and lasted in successive paroxysms of pain for several hours. He would be thus tortured for two or three nights in succession, when the pain would cease, leaving him free for a week or ten days, at the end of which time it would return with unabated force. Mr. A. had consulted several medical practitioners, but had derived little or no benefit. Indeed, the attacks were becoming more severe. There was no history of malaria, but there was clearly periodicity ; yet no effort had, I understood, been made to break through the habit. Quinine had indeed been given, but merely as a general tonic ; and hypodermic injections of morphia had been relied on for relief of the pain. Nor had he received any special instructions about food. Mr. A. breakfasted at 8 a.m., dined at 2 p.m., and, beyond a light meal consisting of a thin slice or two of bread and butter and a cup of tea at 5 p.m., he took nothing till breakfast next morning. The neuralgia availed itself of the open door, and appeared, as stated, soon after midnight, when the power of resistance was least. Amongst the working classes supper is often the principal meal of the day ; but it will be found that they who suffer from neuralgia chiefly at night go, practically, supperless to bed. They never eat much, and have more or less shifting and bearable pain during the day. If unchecked the pain reaches its acme in a succession of paroxysms about 2 a.m. or 3 a.m. I induced Mr. A. to eat more heartily—he was a poor feeder at the best—and to take plenty of fat ; to make the intervals between his meals more uniform ; not to go to bed on an empty stomach ; and always to have by his side something nourishing to take during the night—a sandwich, or an egg-flip, or a glass of milk. I prescribed the following draught :—

Quinæ sulph., gr. xx ;
Liq. potass. arsen., ℥xx ;
Nepenthe, ℥xx ;
Water, ad ʒij.

He was to take half on getting into bed on the night of the expected attack (long experience had taught him when this would probably be), and the remainder directly the pain appeared. The night he took the dose there was no pain till towards 6 a.m., when, feeling its approach, he finished the draught ; and, in Mr. A.'s own words, "the enemy fled at once." For safety's sake the anti-periodic was repeated for three successive nights ; and he remained free for a week. This one period was, therefore, tided over. I cautioned Mr. A. against exposing himself to cold, and particularly damp cold, which, regardless of his age and neuralgic tendencies, he was very apt to do ; and added that he was not to consider himself cured, as the pain would assuredly return. All that we could hope to effect, for the present, at any rate, was to postpone the date of its advent, and to soothe and strengthen the nervous system meanwhile by smaller daily doses of the same remedy, including cod liver oil. My patient took the medicine, but not the advice. Fancying himself better than he really was, he became more careless than ever. The attacks were repeated, though at longer intervals, and Mr. A. then determined to leave our village—a cold locality on a clay soil—for a warm seaport town. The attacks still recurring, he embarked in the month of February on a four months' cruise to the Mediterranean ; but, encountering one day when heated a cold wind that came sweeping down from the Alps over the Gulf of Venice, he had a sharp attack of pleuro-pneumonia, and quickly succumbed.

The result in the following case, where the patient was younger and more tractable, was very encouraging.

Hearing of the benefit—so far as it went—derived by his father, Mr. A.'s son placed his young wife under my care. This young lady, a bride of less than a year's standing, 22 years of age, had for the previous seven years suffered acutely from neuralgia in the right arm from the shoulder to the tips of the fingers and thumb. The pain would recur every fortnight, the attack lasting two or three hours, from about midnight to 2 a.m. or 3 a.m. It would thus return, as in the case of her father-in-law, for from two to four nights in succession. The poor girl would walk about the room suffering excruciating agony. She, too, had consulted several medical practitioners, and tried various nostrums, but without much relief. There was no catamenial or other irregularity, and the cause of the neuralgia could not, at the time, be traced. This patient, too, ate very little ; the body was imperfectly nourished. No doubt the matrimonial year was a trial to her "nervous constitution." She was treated much in the same way as her father-in-law, cod-liver oil being freely given ; and the arm and fingers, after being well rubbed with a soothing and stimulating embrocation (warmed), were swathed in flannel every night. This patient got rapidly well. The attacks—the date of their advent being pushed further and further back—finally ceased altogether. One day, some little time after she had come to consider herself cured, the lady felt a slight irritation in her right breast ; and this reminded her that, a few years previously, the point of a needle had been broken off and remained there ever since. Her husband now took her home, and shortly afterwards I heard that, by the aid of constant poulticing and a bistoury, the bit of needle had been recovered. Doubtless, it was the original cause of the neuralgia, which, I presume, was after a time kept up by habit ; for had the steel continued to cause irritation, quinine would hardly have availed to counteract its influence. It had probably shifted its position. It is, of course, possible that this may have happened only when the lady came under treatment, and that the cessation of pain which was credited to the measures employed was in reality due to its withdrawal. But the evidence in favour of the medicine was, I think, too strong to justify this idea.

(To be continued.)

ON TRANSFUSION.

By J. F. LE PAGE, L.R.C.P.E.

CONVINCED that in the conservative practice of the future transfusion will hold a place of no little importance, and will be more and more extensively resorted to, and seeing that this means at present at our disposal for the performance of the operation are not altogether satisfactory, I have devised an apparatus in which there is an endeavour to combine absolute safety with great facility in use.

Of the transfusors which have been at our service, that of Dr. Aveling is, perhaps, all things considered, the most serviceable ; but it has the disadvantage of requiring very complex manipulation. To put it concisely, each of them requires in its use for the surgeon to be aided by skilled assistance, whilst at the same time there is no safeguard against the injection of a minute quantity of air, however careful and adept the operator may be ; an accident which in all probability would prove fatal to the patient.

The accompanying illustration shows how these disadvantages are overcome. One hand alone is needed to operate the transfusor, and the other hand is at liberty to attend to the efferent tube ; whilst the attention of the surgeon may be divided between the recipient and the donor of the blood. If any portion of air should at first remain adherent, and, of course, unseen, on the inner surfaces of the tubes, and, during the passage of the blood, be carried along with the stream, its course

is with certainty arrested by the glass air receiver into which it must rise. As to the *modus operandi*. The case contains the apparatus, knife, forceps, and a small bottle, which latter is intended to hold a compound powder, composed say as follows:—Carbonate of soda, ten grains; phosphate of soda, two grains; chloride of sodium, thirty grains. One-fourth of the powder should be dissolved in about two ounces and a half of water at a temperature of 100° F. A few drops of alcohol may be added, and the vessel containing the solution placed in another vessel partly filled with water at a temperature somewhat higher. Then, having attached the receiving and delivering tubes, the two extremities of the instrument must be placed in the inner vessel with the air chamber downwards. Now press the lever, press the elastic ball, release the lever, release the elastic ball, and after repeating that process once or twice, turn both taps. It is now ready for use. Raise the patient's arm to the horizontal position so as to facilitate the transmission of the blood to the heart, and having inserted both tubes, one into the supplying vein, and the other into the receiving vein—the right median basilic is, perhaps, the

best—turn the taps, and, in the same order, press the lever, press the ball, release the lever, release the ball, and so on. Precisely one-quarter of an ounce passes out each time. It is expedient, having commenced the transmission of blood, to complete the process without arrest, lest coagula should form. The apparatus is made by Messrs. Arnold and Sons, and their name is quite sufficient guarantee for excellence of workmanship. I must, however, say that my thanks are due to them for so faithfully, so well, and with such precision and care, elaborating from my drawings an instrument of some elegance.

A word as to the cases in which transfusion is indicated. My special intention is that of supplying the obstetrician with a safe and facile means of transfusing blood after post-partum hæmorrhage, where the diastolic system is practically dead, and the heart is dynamically incapable of action in consequence of the absence of fluid to act upon. But transfusion is indicated in many other cases than that of uterine hæmorrhage leading to this condition. For instance, when, after excessive hæmorrhage, the vital fluid is not reproduced, and the nutritive process is so impaired that the persistent anæmia would be the forerunner of phthisis or other grave disease, did we not supply red corpuscles to carry oxygen with which to re-establish those functions which are essential factors in the formation of hæmoglobin. And it is certainly indicated in some cases of hæmorrhage from the bursting of an aneurism, or where a main artery has been divided. With its aid life may at least be prolonged, where the stomach and rectum refuse to retain nutriment in the exhaustion from marasmic disease. It may also be resorted to in the asphyxia of new-born infants, the injection being made through the umbilical vein, having previously allowed a little blood to escape from the umbilical artery. For this purpose a small quantity of blood taken from the placenta and defibrinated will answer very well.

In chronic as well as in acute anæmia we may transfuse, for where the whole blood is altered by toxic or pathological causes it is manifestly advantageous to

improve its quality by the admixture of healthy blood. It may also appear indicated after hæmorrhages from the stomach and intestines, hæmoptysis, and some surgical operations. I would go so far as to suggest, on physiological grounds, its occasional indication in hæmorrhagic fever. In the young who are robust, absorption and nutrition will soon replace the normal quantity of fluid, although for a time it will be inferior in quality to that which was lost, containing less than the due proportion of oxygen carriers, the red corpuscles.

In those previously suffering from anæmia, and in the aged, whose blood is very slowly reproduced, it appears to me that the operation may, with very great promise, be repeated even more than once, at intervals of a few days. In cases of poisoning, when the nature of the poison is unknown, or when an antidote would not be effective, or in pyæmia, might not occasionally a life be saved by alternate depletions and injections of pure blood? In epilepsy it has been used with marked success. And, as in puerperal eclampsia we may presume an excess of carbonic acid and a deficiency of oxygen, may we not here also find it of no little service? I should remark that Dr. Schäfer has most conclusively shown that the action on the blood corpuscles of beef peptones, milk, and some other fluids, when used in lieu of blood, is most injurious.

It has been urged in disparagement of the operation that during transfusion very painful symptoms are experienced, followed, after its performance, by alarming prostration and hæmorrhagic fever. This we may admit to be, in some cases, substantially correct. But what is the cause of all this, but that the vital powers are so stimulated to reassert themselves that the heart and arteries, certainly with intermissions, are making very violent efforts to drive along the small quantity of blood which the system contains? The inference is clear that this most valuable operation has not been so frequently performed as it should have been, and that many invaluable lives have been lost which might have been saved by the immediate restoration of the failing powers of the heart and nervous system which it most strikingly effects.

Durham, November, 1882.

Clinical Records.

TWO CASES OF THE SUCCESSFUL RESECTION OF INTESTINE.

Under the care of Dr. JOULLIARD, of Geneva.

THE first case reported was that of a woman, æt. 63, who had had a hernia which had become strangulated and left a preternatural anus; the second that of a man with left inguinal hernia that had become strangulated. At the operation in the latter case the intestine was found to be gangrenous and perforated in numerous spots; the testicle was also found to be gangrenous. 25 cm. of intestine were removed, together with the testicle, and an artificial anus was established. After the parts had recovered a healthy tone, and not till then, an attempt was made to unite the divided ends of intestine, an attempt that was followed by union by first intention.

He distinguishes between primary and secondary enterotomy. The former designation he applies to resection performed on account of gangrene of intestine, and the latter to similar operation for artificial anus.

He considers the latter much more easy of performance, as well as safer to the patient. The operator, in the latter case, does his work with an empty and dry intestine to work upon, whilst in the former case the bowel may be full of *feces* constantly forcing their way down and impeding the operation. In the latter case, moreover, the gangrene has done its work, and it is perfectly certain that it will not spread beyond the sutures, and the patient is freed from the double risk of strangulation and operation at the same time.

For these reasons Professor Joulliard thinks it a safer course, in cases of hernia with gangrene of intestine, to first

make an artificial anus, and afterwards, when tone and strength have been recovered, to resect and restore the continuity of the gut. In further proof of the correctness of his views, he adduces 25 cases of resection for artificial anus with but 8 deaths, whilst of 44 cases (besides unpublished ones) of primary intestinal resection, 23 were fatal.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 24, 1882.

The President, Professor LISTER, F.R.S., in the chair.

Dr. JOHN CAVAFY on

SYMMETRICAL CONGESTIVE MOTTLING OF THE SKIN.

In this paper two cases of a curious affection of the blood-vessels of the skin are described. The first was a young woman, *æt.* 22 (shown to the Society), who was first seen in March, 1882, when the condition had existed for three years. It began as a reddish mottling of the left shoulder, which gradually spread down the arm, and soon afterwards appeared on the right arm, the cheeks, and both thighs, gradually increasing in intensity. At the date of her first visit the skin of both cheeks was mottled with blotches and irregular rings and streaks of a bluish-red colour; most marked on the right side, not prominent, and covered by normal epidermis. Similar dull, bluish-red maculae and irregularly confluent blotches and streaks, forming reticulated, annular, and gyrate figures, occupied the extensor surfaces of both arms and forearms, and the backs of the hands, being especially distinct over the left wrist. The front and outer surface of both thighs near the knees was similarly mottled, but in a much less degree. The blotches and streaks were not sharply circumscribed, and disappeared completely on pressure, leaving, in some spots, a delicate fawn-coloured pigmentation; the marking also disappeared from the arms when they were held up, and again returned when they were allowed to hang down. The neighbouring skin was normal in all respects, and the general health perfectly good. The girl had rheumatic fever a year before the mottling commenced, but the heart was unaffected; the only departure from perfect health was a liability to "dead fingers" and occasional dyspepsia. She continued to attend for a month with no change in the state of the skin; the markings were always intensified by cold, never completely disappeared, and were throughout unaccompanied by pain, numbness, tingling, or any abnormal sensation. She is still in the same condition. The second patient (also shown to the Society) is a healthy young woman, *æt.* 21, who has been under observation since August, and in whom the affection has existed eighteen months. It began over the ankles, and gradually spread to the legs and thighs; twelve months later the arms became affected, and quite recently blotching has begun on the waist; the face has remained free. The mottling is an almost exact counterpart of that in the first case, but more extensive, and of a deeper bluish red colour over both legs and the front of the thighs, especially near the knees; it is situated on the extensor surfaces chiefly, but also extends slightly over on the flexor sides. The congestion is much increased by cold in this case also. The condition above described is obviously due to venous stasis, or passive congestion of the skin, and appears to be an exaggeration of the marbling often seen on the skins of children and young persons after exposure to cold; but in the above cases, although cold intensifies the marbling, the congestion remains more or less evident at all times. It is probably due to a vaso-motor neurosis, but the share taken in its production by arteries and veins is not easy to apportion. The affection appears to be quite harmless, and has not led to any changes except pigmentation, and that only slightly; but the disfigurement, especially when the face is attacked, is considerable. The treatment employed has not influenced the condition in any way.

Dr. S. MACKENZIE remarked on the rarity of such cases, which, however, presented some resemblance to those in which exposure to the cold induced a mottling of the skin, the effect, however, in the latter being much less in degree.

Dr. CAVAFY's explanation of them was doubtless correct; they bore some resemblance to the mottling produced by heat from fires, but differed in being increased in intensity by the influence of cold. Dr. WEIR MITCHELL had offered an explanation of these cases, which, in Dr. Mackenzie's opinion, might possibly be of vaso-paralytic origin, the peculiar condition set up disappearing as soon as the force to which it was due ceased to act.

Dr. GLOVER asked if the treatment by bandaging had been tried. He had obtained excellent results by this mode of treatment.

Mr. LISTER suggested that the symmetrical character of the mottling pointed to a neurotic origin.

Dr. CAVAFY rejected the explanation that the mottling arose from the toasting influence of fire, his patients having emphatically denied that they were accustomed to expose themselves in this way. The slight amount of pigmentation and ready disappearance of the marbling on pressure, pointed to the same conclusion. In connection with the reason for the appearance which had been proffered, he related that one of the two patients exhibited, frequently suffered from "dead fingers," while the other fingers frequently became numb, but never white. Both patients were quite healthy. The suggestion of a neurotic origin deserved consideration. Treatment by bandaging was impracticable, the principal site of the mottling being the upper limbs and face.

Mr. JAMES E. ADAMS on a

CASE OF LUMBAR NEPHRECTOMY FOR CARCINOMA.

Patient, male, *æt.* 39. Intermittent hæmaturia for two years, pain in right loin. Laterally profuse hæmorrhage from kidney, leading to marked anæmia. Blood-pus, triple phosphates, and epithelium in urine. The disease was clearly located in right kidney, but its exact nature was not certain. The operation was undertaken in order to explore, and if necessary, to remove the right kidney. By an incision parallel with the lower border of the last rib, the kidney was easily exposed, and found to be the seat of a new growth, which had increased its size to about double the normal. In order to extract the organ, it was necessary to enlarge the incision upwards; the organ was adherent to the peritoneum, and in separating it the serous cavity was opened. Owing to the size of the tumour, the ureter and vessels could not be tied separately, but were encircled *en masse* by a whip-cord ligature. The peritoneal wound was closed with a catgut suture; the skin wound was freely drained. The hæmaturia ceased at once. The wound healed in a few weeks, but the patient gained no strength; suffered much throughout from cough, and was transferred back to the care of the physician, and died forty-four days after the operation, with effusion into both pleurae plugging of left renal vein, and numerous secondary deposits in lumbar glands and on ribs.

Mr. CLEMENT LUCAS, while congratulating the operator on the success of his proceeding, regretted that the case was otherwise an unfavourable one for it. So many of these cases afforded the typical symptoms of calculus that it would probably be found a number of so-called cases of renal calculus, would on proof turn out to be quite other diseases. Last year he had himself twice discovered such errors of diagnosis; in one the patient experienced a rigor the night preceding the operation for exploring the kidney, in which, when punctured to a depth of one and a-half inches, no stone was found to be present. The kidney, which did not bleed when pricked, was puckered up, and was probably strumous in character. Mr. Lucas would strongly encourage physicians to aid their diagnosis in connection with kidney disease by employing the needle to explore the organ. In both the cases mentioned primary union took place without pain or immoderate discomfort, and the temperature was never over 100°. He was convinced there was no more danger in exploring the kidney than in making a like incision into the calf of the leg.

Mr. GOLDING BIRD asked whether the enlargement of the original opening mentioned by Mr. Adams was made in the vertical direction or not; and, further, whether he would recommend the lumbar or the abdominal operation?

Mr. FOWLER related particulars of a case in the Middlesex Hospital in which calculus disease of the kidney was suspected. On exploring the organ, however, this was found not to exist. The wound subsequently healed well.

Dr. DOUGLAS POWELL declared his belief that even when a calculus did exist in the kidney, and operation with a view

to its removal was resorted to, the result was disastrous. What should be desired was a better means of diagnosis without exploration, whereby at least some risk would be removed. Cases did occur in which calculi existent in the kidney passed away to the bladder, and improvement should be sought for in the direction of diagnosing the size of such stones as might be present. He believed that pain as acute as that experienced from the presence of a large stone in the kidney, might co-exist with a small calculus, and in proof cited the case of a patient in the Middlesex Hospital in whom excruciating pain attended the presence of a small stone, which, having been passed naturally, subsequent exploration of the kidney showed to have been the sole exciting cause of the pain.

Mr. BARKER considered that Dr. Powell had offered in his objection, viz., difficulty of diagnosis, an argument in favour of exploration. Nephrectomy would have to be decided by the condition of the kidney in regard to tissue destruction.

Dr. WILBERFORCE SMITH recommended copious ingestion of water with the object of assisting the excretion of calculous deposits in the kidney.

Mr. WARINGTON HAWARD wished to know whether, with a view to arriving at a diagnosis between stone and carcinoma, Mr. Adams had made a careful prior examination of his patient under an anæsthetic? By such means, detection of growths in the abdomen and pelvis was much facilitated, and a stone might have been felt even. Was the frequency of micturition observed independently of the presence of blood in the urine? Renal calculus in itself usually created vesical irritation.

Mr. HOWARD MABSH asked whether a large kidney really was to be detected under anæsthetics? Last year he and his colleagues had failed to make out any increase of size of this organ in a patient examined during anæsthesia, and yet on subsequent post-mortem examination such enlargement was plainly found.

Mr. JAMES ADAMS explained that the first opening made during the operation he had described was enlarged by means of a second vertical incision joining it at right angles. He would adopt the abdominal method if the kidney were a large one. He did not agree with Dr. Powell as to the disastrous results of renal surgery, or that exploration was too rashly resorted to. Such operations were undertaken at the request and by advice of physicians, and then only in desperate cases which offered no prospect of other relief. Removal of the kidney would be made dependant on the condition of its structure. His patient had been carefully examined while under the influence of anæsthetics. He thought a large kidney in a large patient might easily be overlooked.

Dr. DYCE DUCKWORTH ON

TWO CASES OF SUBCUTANEOUS RHEUMATISMAL NODULES.

Case I.—S. C., æt. 24, domestic servant, came to St. Bartholomew's Hospital on account of painful swellings upon the right hand and knee. She had had no serious illness, no rheumatic fever or chorea. Suffered for eight years past with pains in the joints and limbs. Cracking in the larger joints was noticed. The nodules began eight months previously on the right hand, elbow, and knee; and are found to be quite subcutaneous, painful on pressure, and attached for the most part to sheaths of the tendons or deep fasciæ. The fingers were knotty at the joints, and the right little finger was twisted outwards at the last phalanx (not as the result of injury). The first sound of the heart was found roughened and somewhat reduplicated. The urine was alleged to be occasionally thick. (The patient was exhibited, and casts of the right hand and knee were also shown). In three months' time it was found that some of the nodules had grown larger, and that new ones had appeared. Signs of slight hypertrophy of the left ventricle of the heart were noted, and the first sound was rough and reduplicated at the apex. Treatment by cod-liver oil and iodide of iron and potassium had not proved of material service, and there were still articular pains. The nodules ached more in damp weather. *Case II.*—E. L., æt. 9, a school girl, had suffered from pains in the feet, knees, and arms for two months, and at that time nodules were first seen on the ankles, elbows, and knees. The legs and hands were also swelled "as if dropsical." There was no history of chorea. Nodules of various sizes were found on the sheath of extensor tendon, on the metacarpus, on the olecranon, on the spine of a dorsal vertebra, on both patellæ, and on an external malleolus. The nose and finger-ends were clubbed. The

cardiac physical signs indicated mitral regurgitation. In three weeks the nodules on the patellæ appeared larger. The child ceased attendance, and its parents could not be traced subsequently. A cast of one knee was taken at the first visit.

Remarks.—Both cases were well-marked examples of rheumatismal subcutaneous nodules. Both occurred in females, as is found to be the case in most instances. The nodules have persisted longer in the first case than has hitherto been previously noticed, fourteen months against five, and the age of this patient is more advanced than in most cases recorded. The heart was affected in both patients. All the points noted supported the previous observations of Drs. Barlow and Warner as communicated last year to the International Medical Congress.

The PRESIDENT observed that it was remarkable such a disease should only recently have been recognised, and that "rheumatic nodules" were certainly a novelty. He had been struck by the fact that the heart should be affected in patients suffering from a form of chronic rheumatism, cardiac lesions being assumed to be associated with acute developments of the disease.

Dr. H. GREEN had seen but a single similar case, that of a boy with subacute rheumatism. In it the nodules were very marked, but produced no symptoms of which the patient complained. There was, however, distinct mitral disease, which was in clear relation with the growth of the nodules.

Dr. BARLOW said a few of the cases observed bore resemblance to rheumatoid arthritis; in the majority, however, heart mischief occurred and should always be suspected. Some years ago he had a boy under treatment for this disease, in whom large nodules appeared on the elbows, and as these increased, so, at the same time, did signs of heart complication present. The treatment adopted was by salicylates. In all cases the heart affection should be carefully watched for.

Mr. GODLEK asked if it had been ascertained what structures exactly were the seat of deposition of the nodules? He wished to know because he had treated a case in which such growths occurred in the palm, and were considered to be ganglions.

Dr. BARLOW explained that he had satisfied himself the nodules were attached to the deep fasciæ, and not, as asserted by French writers, to the periosteum.

Mr. BARKER inquired at how late a period in life the nodules might appear?

Mr. STOKES mentioned the case of a woman, in whom, at middle age, such nodules made their appearance, but subsequently they disappeared. Salicylic treatment was unavailing in this case.

Mr. GOLDING BIRD adduced evidence in support of a theory that the deposits were allied to thickenings of the fasciæ.

Dr. DUCKWORTH described the growths as consisting of delicate fibroid tissue, occurring as a rule in young persons under eighteen, but sometimes met with in older patients. He thought the less surgical treatment they were submitted to, the better it would be.

PLAS NEWYDD, the ancestral mansion of the Marquis of Anglesey, which has been unoccupied for some time, has been leased for a term of years for adaptation into an establishment for dipsomaniacs.

IN addition to the distinction of C.R. mentioned in our last as having been bestowed upon Surgeon-Major Scott after the Egyptian campaign, Her Majesty has also personally decorated this gentleman with the war medal and the insignia of the Order of St. Michael and St. George.

WE are glad to learn that at a meeting of the Sunderland Board of Guardians on the 16th inst., the recommendation of the Finance Committee that Dr. Ridley Dale's salary as medical officer for Sunderland parish be increased was unanimously carried, in consequence of increased duties efficiently performed.

Special.

STUTTERING, STAMMERING, AND LISPING. (a)

WHEN a member of the medical profession publishes a work the sole end and aim of which is an advertisement, and when the work is written in a popular style, i.e., addressed to the public, it naturally takes the form best adapted for the purposes for which it is intended.

If the work is adorned with an introduction, this will set forth in florid or extravagant language the delights of being free from the disease or affection treated of. It will then, in a harrowing manner, picture the torments suffered, and the immense disadvantages laboured under by those who have the great misfortune to be the subjects of the said affections. It will then give the anatomy and physiology of the parts implicated; then an attempted scientific explanation of the phenomena exhibited; then in a perfunctory and very imperfect manner the reader will be made acquainted with some of the routine of treatment; whilst throughout the work numerous references to the author's many years' experience, his theory, his researches, and his wonderfully successful treatment will meet the eye of, it may be, the anxious sufferer, who will, in his bewilderment, carry away but one idea from the perusal of it, viz., that there is balm in Gilead, i.e., wherever the author may live, that there is a physician there.

The work before us is constructed exactly on the plan sketched above. Thus, the introduction—"Human speech" (what other animals are possessed of the gift our author does not tell us)—"this wonderful union of function of mind and muscle is indisputably the most precious gift wherewith Nature has distinguished man amongst all things created. We win through the magic of our words, love, friendship, respect; in short, it is to speech that we are indebted as well for our spiritual as our bodily well-being." Dumbness, and even stuttering and stammering, on the other hand, are repeatedly spoken of as *Verhängnissvoll* (pregnant or big with fate). Physiology is spoken of as a knowledge of the human body and of the proper performance of its functions. The epiglottis is likened to the lid of a snuff-box that remains open generally, but can be closed at pleasure.

The book contains a concise and clear account of sound and its production, and of the production of vocal sounds in particular. The sound represented by each letter, or combination of letters, is treated of separately, and the mode of its production clearly explained, generally by means of an illustration, showing the relative positions of the various parts of the vocal organ in the act of producing the sound under discussion. From a scientific point of view this part of the work is much superior to any other.

When Dr. Coën comes to treat of the subject proper we find he differs in the nomenclature from those who have preceded him, and that he puts an arbitrary meaning on common words, so that he is obliged to explain them. Many people, professional as well as others, look upon stammering and stuttering as

different names for the same defect. For instance, M. Chervin, Director of the Institut des Bégues, Paris, says: "Some whose 'stammering' is in general only slight, under the influence of emotion find themselves unable to articulate a single sound." From the passage quoted it will be seen what is meant by the word "stammering." Dr. Coën calls this defect, "stuttering," "das Stottern," and by "stammering," "Stammeln," he means something entirely different. We cannot do better than quote his own words:—"We have already explained that the causes of stuttering are not to be sought in the organs of speech, but in those of respiration. When we make a stammerer speak or read we fail to notice in him the slightest trace of that peculiar spasm of the organs of speech, of the muscles of the face, or those movements of the head or arms which are always present when an individual stutters; but we see and hear the patient quietly and calmly speak and read. We see also that the stammerer has no free moments, as the stutterer has, the defects remain the same, on every occasion and always." He then goes on to describe what stammering is, and describes it as—

1. The imperfect formation of one or more vocal sounds.
2. The complete omission of some sounds.
3. The exchange of some vocal sounds for others.

As examples of stammering he gives the words *Frankreich*, pronounced *Flankreich*; *London*, *Nondon*; *Erde*, *Ende*, &c.

But enough has been said to show his meaning. We fail to see that his classification is more perfect than that of Colombat de l'Isère, or that of Godard and Chervin. McCormac said that the chief cause of stuttering was in the attempt to phonate with empty lungs. Our author says the same thing, and prides himself on it as a discovery. Godard and Chervin treated their patients by systematic drilling, commencing with respiratory gymnastics. Dr. Coën treats his patients in the same way, and professes to have hit upon a new method. Besides the ordinary defects of speech, the work treats of imperfect development of speech, dumbness without deafness, deaf-mutism, and the speech of imbeciles and idiots. In the chapter on deaf-mutism many interesting facts are recorded. He mentions from Von Frieriep some examples of deaf-mutes who distinguished themselves in various occupations; some as artists, copper-plate engravers, and mechanicians, one as a mathematician, several as writers, two as poets, and one as a musician! The latter wrote a work on the formation and variation of sound.

The work is scarcely satisfactory to the professional reader, as he feels a consciousness all the time of his reading it that it is really intended for an entirely different class. If he be indifferent to such feelings he will no doubt obtain both pleasure and profit from it; one of the items of profit being a correction of a widely-spread error, viz., that lisping and stammering (in the author's sense) are not due to any organic imperfection, but to involuntary imitation, or dulness and ignorance on the part of those who possess these graces of elocution.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Birkenhead 13; Bristol 16; Leicester 17; Plymouth, Derby, 18; Brighton 19; Portsmouth, Wolverhampton, Norwich 20; London, Edinburgh, Bradford, Salford, 21; Bolton, Cardiff, 22; Sheffield, Newcastle-on-Tyne, Birmingham, Leeds, Oldham, 23; Blackburn 24; Huddersfield, Hull, Nottingham, 25; Dublin 26; Liverpool, Halifax 28; Glasgow, Manchester, Preston, 29; Sunderland 30.

(a) "Das Stottern, Stammeln, Lispeln und alle übrigen Sprechfehler, so wie die Entstehung, Verhütung und Heilung dieser Uebel auf Grundlage vielfähriger Erfahrung nach den neuesten wissenschaftlichen Forschungen gemeinverständlich dargestellt." Von Dr. Rafael Coën, Spezialarzt für Krankheiten der Hals und Sprachorgane und Leiter der ersten österreichischen Heilanstalt für Sprachkranke in Wien. Mit 16 Abbildungen. Zweite verbesserte und bedeutend vermehrte Auflage. Wien, Pest, Leipzig. A. Hartleben's Verlag.

"Stuttering, Stammering, Lispings, and other Defects of Speech; the Origin, Prevention, and Cure of these Evils explained in a popular style, in accordance with most recent scientific investigations, upon the basis of many years' experience." By Dr. Rafael Coën, Specialist for Diseases of the Throat and Organs of Speech, Conductor of the first Austrian Institute for Defects of Speech, Vienna. 16 Illustrations. Second Edition, improved and considerably enlarged. Vienna, Pesth, Leipzig. A. Hartleben's Verlag.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 29, 1882.

"NEW DISEASES."

By a curious and undesigned coincidence the suggestions contained in our last issue on the subject of so-called new diseases were made at a time when this subject receives prominence in connection with more than one important event. Thus, the subject chosen by Sir James Paget as that of the Bradshaw Lecture to be delivered at the Royal College of Surgeons, on the 13th inst., is "New and Rare Forms of Disease," and at the Clinical Society on Friday evening last, Mr. Lister, while discussing a case of subcutaneous nodules reported by Dr. Douglas Powell, was led to express surprise that the "new" disease described had hitherto been so little recognised. Indeed, so frequently are we being reminded of the progress which is being made in medical research by the occurrence of "new and rare forms of disease" that there is some reason for declaiming against improper employment of terms only too likely to be delusive and misleading.

It is matter of fair inquiry as to what conditions serve to entitle disease to be regarded as new, since the most comprehensive view of medicine is powerless to include the majority of existing ailments. Properly, to define the term as now employed necessitates the separation, by a process of exclusion, of every known disease from that which is denominated by it; moreover, to effect any such operation, would be, under existing circumstances, an impossible task, inasmuch as those pathological distinctions which afford the most permanent basis of classification possess, even now, but a temporary

value, and are liable to material modification with the discovery of fresh signs. It is a fault of the pretentiousness of modern methods that every fact which is unfamiliar necessarily seems new; it is equally a consequence of modern perfection of scientific knowledge that innumerable phases of disease must for ever remain wholly unseen by the majority of practitioners. To this, added to the admirable diligence displayed by the crowd of enthusiastic observers, each year recruited by zealous spirits emulous of distinction in the field of research, we owe not only the tremendous benefits accruing from increased activity in the sphere thus peopled, but also a less satisfactory exhibition of name giving propensities which have lately received so marked an impetus.

Applied to the human organism, the term new, in relation to diseases, is a misnomer. Unless we are grossly deceived in our reading of natural laws by the light of Evolution, novelty is an incompatible element in this connection. We do not, when dealing with concrete discoveries of naturalists and physicists speak of them as new in the same sense as we speak of "new diseases," and yet the application of the term would be as rational to the one series of phenomena as to the other. A hitherto unknown asteroid, or worm, or planet is recorded as new to science, it is true; but only in such wise as being hitherto unrecognised is it so spoken of. There is no pretention in the use of the word; no suggestion that similar star fishes, or planets, or parasites have not existed for ages eternal; or that the discovery is anything more than a revelation of previous ignorance.

In medicine, however, there is a dangerous tendency in the opposite direction; all the more dangerous, too, because it is the tendency, not of the few to whom the real truth is apparent, but of the many who are unable or unwilling to reflect on the proper meanings that should be attached to accustomed phrases. The cultivated physician who puts the discovery of "a new disease" on record, doubtless appreciates the vanity of the title, and would be among the foremost to condemn its employment. But he pursues the customary course, nevertheless; possibly because it never has occurred to him to consider the mischief he is perpetrating—rarely, if ever, for want of perception of the unreality of his so-called novelty. The mischief, however, is at least as much, under whatsoever circumstances the title is bestowed; it imposes on the thoughtless, and excites impressions among them which will fatally bar their reception of truth when it is presented to their minds, for the majority of medical men are anything but discoverers. They accept in all literalness the announcement of new diseases, and, ignoring analytical methods, unhesitatingly regard the appearances described as new in the sense of primarily created and hitherto non-existent.

It would be rank injustice to ascribe any such unphilosophical intention to the originators of terms, descriptive of "new diseases." Sir James Paget has shown himself too diligent a student of the doctrine and teachings of evolution for it to be for a moment assumed that he is forgetful of the influence of evolution on disease as on every other condition of life.

That modifications occur in the modes of exhibition of morbid processes, and that the effects thereby produced on the organism will vary from generation to generation, is abundantly probable, even if it be even yet unproven. But this is entirely different from the admission that, according to conditions of which we possess any definite and present cognisance, diseases of the body can arise *de novo*; and yet if there be any meaning at all in the term, "new diseases," this is what it expresses, and this only. It cannot, therefore, but be hurtful to true progress so to hamper advance as to clog it with the introduction of gratuitous untruths. The path onwards cannot be swept too clear of spurious productions of every description, and nothing can be gained by making a pretence of knowledge to which no claim is possible. A new disease implies something that had no existence before, whereas, if it were spoken of as an "unrecognised" disease, it would be so at the expense of professional acumen; it would be an admission of previous failure to detect it. This explanation, it cannot be concealed, underlies the whole question; and when examined how unpromising a spirit it displays?

It would be interesting to examine the grounds on which these "new diseases" are dignified with the appellations they receive. It would be a task of some length, it is true, but one which might well be worth the performing, and we almost regret that we cannot enter on it now. Many of them have received, and are receiving, careful attention from investigators able and willing to assign a rightful value to the pretensions advanced on their behalf. Some few of them obtain current rank as well-identified diseases about which no difficulty can any longer be felt, and concerning which, once duly enrolled in the nosological index, further doubt would be vain. From the status of "new diseases" they have sunk to well-recognised maladies, which, now they have been faithfully portrayed and described, cease any longer to be either new or rare, and will in future centuries be as regularly included in text-books of medicine as the most ancient of all complaints.

This certainly ought in itself to be instructive, and to lead to the inculcation of a more philosophical spirit among the followers of the art and science of medicine; to such self-abnegation as is contained in the admission of "unknown" as a substitute for "novel;" and to the prosecution of such scientific study of disease as shall for ever prevent similar confusion of ideas. Such confusion alone could cause it to be imagined that the course of Nature might so far be interrupted as to give rise to a "new" disease, ready-made and characteristically marked to the hand of the first observer astute enough to turn the occasion to his own advantage.

All honour and every distinction to those whose learning enables them to extend the limits of our knowledge of diseases; but let us be honest and fair to Nature in making our description of them. No permanent advance can be looked for until explanations of phenomena in living animals are made in accordance with the laws which regulate all organic existence.

THE RIGHT HAND OF FELLOWSHIP.

AN important significance attaches to the banquet given last week by the members of the medical profession in civil life to their brethren of the Army, Navy, and Indian Medical Services who have returned from Egypt. That important significance rests in the *rapprochement*, which is thus inaugurated between the members of the great professional body whose sphere of labour is city, town, or country district within the limits of the United Kingdom and those whose sphere of action, whether by sea or land, embraces a very large portion of the inhabited globe. This is as it should be. The great object of medicine is the relief of human suffering. It is, therefore, right that one spirit of brotherhood should unite the several orders of that profession, alike in view to the general interests of the profession itself, the good of the public, and the well-being of individual members. In this sense the branches of the public service represented by the guests who on the 21st ult. partook of the princely hospitality of their civil brotherhood are prepared most heartily to accept the right hand of fellowship thus held out to them. They fully appreciate the honour thus done to them as a body, and they are happy to believe that in many ways and respects great benefits will accrue from the conditions thus happily begun. Never before has so great and pronounced demonstration of its kind taken place as on this occasion. Not alone the highest and most distinguished dignitaries of the profession in the metropolis were present to give countenance to it, but so also were the highest professional representatives from the Universities of Oxford, Cambridge, and Dublin, and men from distant parts of the kingdom. The Duke of Cambridge was, unfortunately, unable to be present. In a letter to the Chairman, His Royal Highness said that he should gladly have availed himself of this opportunity of showing his interest and cordial support to the Medical Department of the Army and to the medical profession at large; for he is well aware how closely and intimately our mutual professions are connected, and how impossible it is for the army to exist without the skilful aid of our medical friends. Sir Garnet Wolseley expressed the disappointment to him it was to be prevented from being present to do honour to those whose services and whose devotion to their military duties are so highly appreciated in the Army. Mr. Childers expressed his regret that he was unable to be present, as he should have specially wished to do honour, as far as in him lay, to the medical officers who served in Egypt with so much distinction and ability.

Sir William Jenner having proposed the usual loyal toasts, Sir James Paget proposed "The Navy, Army, and Auxiliary Forces." He observed that they were proud of the men of their profession who, along with their scientific and medical knowledge, showed, as members of the Army Medical Department, courage, self-denial, and endurance for their country's good whenever they were at war. The Earl of Morley, in reply, observed that very many officers of the highest distinction had testified to the zeal and untiring energy of the Medical Department throughout the late campaign. In proposing the toast of the evening, Sir William Jenner alluded to the nature of the duties of army surgeons in the field. He observed

that they were called upon to operate when shot and shell were dropping around them, and he feelingly mentioned the late Surgeon-Major George Shaw, who, at Kassassin, while at his post of duty, fell, pierced by a bullet. He remarked that to preserve a cool head and steady hand under such circumstances indicated high devotion, mental power, and training; and that all honour should be rendered to those who conducted themselves as medical officers under such trying circumstances. Therefore it was that this representative assembly composed of the most renowned practitioners of medicine, surgery, and midwifery, desired to express their conviction that those officers did their duty, that this is a sufficient reason why they should receive a hearty welcome, and that their civil brethren desire to draw closer the ties which unite them to the military members of their common profession.

An indication of the importance in regard to the profession among the public services at large of the demonstration in question transpired during the banquet, the incident being the receipt of a telegram from Berlin conveying the gratulations of the army surgeons assembled in the German capital. In the reply to that telegram, despatched forthwith, there was, no doubt, implied the extension to them also of that bond of union so happily established by means of the banquet of welcome to the medical officers returned from Egypt. May it long continue!

THE ARMY MEDICAL DEPARTMENT AND MILITARY COMMAND.

Few things sound more plausible to civilian members of the profession and to the public generally than the stock arguments so loudly advanced by military officers and the military press against the concession to medical officers of military command of any description. It is earnestly proclaimed that medical officers will become the subjects of such ecstasy that they will at once seek to obliterate all traces of that profession which it has cost them four years, and much money, to acquire; that they will regard the title of "Dr." as an indignity, and endeavour to sink the appellation of an University degree in the hope of being temporarily mistaken for a subaltern of the line; that they will so clank their spurs by the bed-side of their most nervous patients as to produce the direst results; and will, when in confidential converse with their female patients under the most interesting conditions, so far imitate the much-resounding tones of the infantry adjutant as to call little spirits from the vasty deep; and much more in the same strain. Such are, in few words, the warnings uttered by military wisdom against the danger of conferring on medical officers the command of their own orderlies and their own hospitals. Let us inquire what is this mysterious power which, when entrusted to medical hands, produces such awful consequences. Doubtless, for the handling of bearer-companies, a knowledge of drill equal to that possessed by a captain of the line, and shared in unequal proportions between him and an intelligent lance-corporal would be indispensable. This would necessitate scarcely more mental effort than called into action in acquiring the course of calisthenics

taught in a young ladies' boarding school. In addition to this must be learned the scale of punishments laid down for military offences; and then the medical officer will have added to his professional education the amount of military lore which every captain of volunteers masters in a few months during his leisure hours, and which has neither been found to incapacitate him from discharging his legitimate calling in life, nor has had the effect, like old Father William in Wonderland, of making him stand on his head. Surely it is time that, when questions of vital importance to the army and the nation are being discussed, a little common sense should be used.

Notes on Current Topics.

The Academy of Medicine of Ireland.

The Sectional Councils of the Academy the election of which we announced in our last issue have held their first meetings during the past week. The President of the Academy for the next three years is Dr. J. T. Banks, Physician to the Queen in Ireland, and Representative of the Royal Irish University on the General Medical Council. Mr. Thomson, of the Richmond Hospital, was elected General Secretary, and Dr. Robert MacDonnell, Treasurer. At their first meetings the Sectional Councils have appointed their secretaries and their delegates to the General Council of the Academy, as follows:—Surgical Section: Secretary, Mr. Stokes; Delegates, Mr. Porter, Surgeon to the Queen, and Dr. A. H. Jacob. Medical Section: Secretary, Dr. Montgomery; Delegates, Drs. Finney and Grimshaw. The Presidents of the foregoing two sections are the Presidents of the Colleges of Physicians for the time being. Pathological Section: President, Dr. Purser; Secretary, Dr. Bennett; Delegates, Dr. T. E. Little and Dr. Foot. Obstetric Section: President, Dr. Denham; Secretary, Dr. Neville; Delegates, Drs. Atthill and Macan. The first meeting of the Academy will be that of the Pathological Section, which will take place on Friday next, at 8 p.m., at the College of Surgeons, and Dr. Purser will then deliver an inaugural address. The Academy has enrolled already over 150 Fellows, besides several Members and student Associates, and everything seems hopeful for a successful career.

It may be well to remind the profession that if they desire to be admitted to the Academy they must send in their names before the last day of the year, or else pay an entrance-fee and submit themselves to a subsequent election by ballot. All subscribing members of the four co-operating societies are entitled to come in as Fellows or Members if they send in their names before the 31st of December, with the subscription of £2 2s. or £1 1s. respectively. Those who are not subscribing members of a Society or Fellows of either of the Colleges, and all those who allow the year to pass without placing their names on the roll, will have to be elected by ballot of the General Council, as we have said, one black bean in four rejecting.

Some excitement has been caused in the Academy by the circumstance that the name of a certain Dr. Beaney, a remarkable practitioner residing in Melbourne, had been submitted for the Fellowship of the Academy. The visit

of this gentleman to Dublin some years ago, his entertainment at Trinity College, his dinners to himself, and various other circumstances in connection with his professional career, are in the knowledge and recollection of our readers. It was certainly not expected that he would venture to present himself for any place of honour in the Academy, and we believe that his name has not been submitted in any regular form, and we hope, therefore, that the Council of the Academy will be spared the necessity of expressing any opinion as to the eligibility of Dr. Beane.

It has been suggested that the inauguration of the Academy might well be marked by some special festivity, and a *conversazione* has been proposed; but the Council has not, as yet, we believe, arrived at any determination on the subject. We think the suggestion an excellent one, and that, if it were carried into effect, the Academy would receive a great stimulus and be materially aided in its work, and we therefore trust that it may be found possible to arrange such a celebration.

A Very Serious Charge.

A MEDICAL practitioner in large practice at Melbourne has been called on by the Chief Secretary of the Colonial Government of Victoria to resign certain official appointments held by him, in consequence of the unusual circumstances attending the death of a patient under his care. Dr. Barker, the gentleman referred to, was consulted by a married woman for relief from trouble produced by varicose veins; she had previously, according to the statement of two other women, expressed her intention of seeking to be rid of a child with which she was pregnant, and Dr. Barker avers also that she solicited him to procure the abortion, but that he, of course, at once refused to do so. Unfortunately, the woman died during a visit to his surgery, the cause of death being certified as epilepsy and varicose veins. With lamentable want of discretion, Dr. Barker took steps for the burial of the body, at his own expense, and without first causing an inquiry into the circumstances to be held, the coroner, who should have insisted on this formality, himself a medical man, so far assisting the proceeding as to give an order for the purpose. The facts, on becoming known, naturally excited much comment, and eventually the body was exhumed, six weeks after death, and examined prior to a regular inquest. It was then found that a wound, evidently made *ante mortem*, existed in the mucous membrane (its exact situation not being stated); and the jury decided that deceased had visited Dr. Barker with the object of having abortion procured, but that the cause of death could not be ascertained. This, it will be at once seen, virtually throws aside the certificate of death given by Dr. Barker, who consequently labours under a suspicion of the very gravest character. At the inquest neither the physician nor the husband of the deceased appeared as witnesses, an omission which complicates the unsatisfactory features of the case, and one which it is impossible to overlook. We cannot but regret the facts, and the necessary publicity they have attained; but at the same time it should be recorded that Dr. Barker has demanded a full and impartial inquiry, which will doubtless be made without delay. He

has also written a long letter in explanation of his conduct, which, together with the result of the pending investigation, will, we hope and assume, entirely clear him from all blame in the matter.

The Medical Reform Bill.

ON Wednesday last a deputation from the British Medical Association had an interview with Lord Carlingford, President of Council, with whom was Mr. Mundella, the Vice-President, with reference to the amendment of the law relating to medical education and practice. The deputation, which was introduced by the Duke of Westminster, consisted of Dr. Strange, President of the Association; Mr. Wheelhouse, President of Council; Dr. Wade, Treasurer; Dr. E. Waters, Chairman of the Medical Reform Committee; Dr. Chadwick; Dr. De Bartolomé; Mr. C. Macnamara; Dr. A. P. Stewart; Mr. Ernest Hart; Dr. Glover; and Mr. A. T. Norton. Dr. Waters made a statement on the subject of medical reform, after which remarks were made by Dr. Glover, Mr. Ernest Hart, and Mr. Wheelhouse.

We are unable to enter upon the subject of this deputation in our present issue, but we have to express our satisfaction that the medical reformers are making manifest intention to keep the subject alive during the next session of Parliament. The occasion is favourable for medical legislation—Parliament has before it the advice of the Royal Commission. It has no obstructive "burning question" in view to hinder the progress of domestic legislation. It will have—let us hope—effectually silenced by the procedure rules the mulish hindrance to business offered by the Irish irreconcilables, and it is thus in a good position to grapple with the wants of our profession. No difficulty exists in making a fair working law on the subject save the opposition of the Scotch colleges, who will undoubtedly fight hard to save their pockets and maintain the educational abuses on which they have fattened under the benign *régime* of the Medical Council. But such opposition can avail nothing if the profession is united and active. We expect it will show itself so.

Death of Professor Pirrie.

ON Tuesday, the 21st inst., Dr. W. Pirrie, ex-Professor of Surgery in Aberdeen University, died at his residence in Union Street. This news will be received with great regret by a very large circle to whom the deceased professor was well known either officially or personally. It is but recently that Dr. Pirrie concluded a period of fifty years of service in the University of Aberdeen, and it was hoped that the increased repose thus obtained, and rendered necessary by failing health, would have resulted in complete restoration of strength. The end was hastened, however, by an acute attack of inflammation of the prostate with supervention of septicæmia, beneath which he gradually sank. Professor Pirrie's name is well known in connection with his work on surgery, and by the success with which he operated in cases of disease involving the elbow-joint, over one hundred resections of this part having been performed by him before the first publication of his results. An obituary will be found in another column.

No Thanks to the Doctor.

In the House of Commons, last week, Sir Trevor Lawrence asked the Secretary of State for War why the name of Surgeon-General Hanbury, commanding the medical branch of the Egyptian expedition, had been omitted from the Parliamentary vote of thanks to the general officers and others; whether Surgeon-General Hanbury did not hold the relative rank of Major-General, and was of the same rank as the other Majors-General whose services were specially acknowledged in the despatches of the General the Commander-in-Chief of the expedition. In reply to the first question, all Mr. Childers had to say was: "Speaking for the First Lord of the Treasury and the First Lord of the Admiralty, who with myself were responsible for the language of the vote of thanks, we followed the precedents, according to which it is not usual to name departmental officers, and I see no reason for enlarging the already long list of names embodied on these occasions." As to the second question, he admitted that Surgeon-General Hanbury does hold the relative rank of Major-General. We venture to say that, as the purpose of a Parliamentary vote of thanks is to encourage meritorious service, it is an exceedingly bad "precedent" which makes it "not usual to name departmental officers." Such a rule is a stray relic of the happily past age of army purchase, old fogginess, stocks and pipeclay, and Mr. Childers would distinguish himself, and act up to the traditions of his party, if he would wipe out an effete rule which acts so unfairly. Parliament wants to know who has well and faithfully served his country, and does not want to be limited in its thanks by "precedents," and there can certainly be no justice or equity in confining the acknowledgments of our rulers to the *soi-disant* combatant branch of the service.

False Certificates.

ON Thursday last, Mr. Benjamin Thornton, L.S.A., who practises as a surgeon in Hackney, was charged at Worship Street Police Court with having wilfully made and given a false certificate of death. The prosecution was instituted by the registration authorities in respect to the death of a certain child, whom, it was alleged, the defendant had not seen within the meaning of the declaration on the certificate, an assistant having attended the case. For the defence it was contended that no intentional fraud had been committed, and that Mr. Thornton was unlikely to subject himself to such imputations as would follow from his designedly acting in the manner charged against him. The magistrate, Mr. Hosack, held that the Act of Parliament was most explicit in such matters, and that Mr. Thornton had knowingly, but not corruptly, broken the law. He, therefore, imposed a penalty of £5, with 2s. costs. The money was, of course, paid. We must congratulate Mr. Hosack and his brother magistrates on the determined way in which they are dealing with every infringement of the Registration Acts brought before them; and we trust the lessons that are being so frequently taught to practitioners in this connection will be fruitful of good results. In the particular instance above recorded Mr. Thornton was doubtless without any desire to commit an illegal act; but it is difficult to see why, the assistant according to the evidence being qualified, his

employer should not have been content to let him sign the necessary certificate. Under the circumstances no particular advantage attached to Mr. Thornton's signature any more than to that of the person who ought to have certified the death. On the contrary, it afforded the appearance at least of deception; and the prompt punishment accorded to the legal offence committed is a satisfactory evidence that we may hope for speedy improvement in what has admittedly become a frequent practice.

Extravagant Specialism.

In a lengthy and amusing letter addressed to an imaginary gynaecological specialist by a brother practitioner, in the *New York Medical Record*, the writer makes some very pertinent observations, which might with equal appropriateness be addressed to British authors. The following concluding paragraph is especially applicable in this respect:—"In your zeal to restore damaged perineums, and to sew up or cut down cervixes, remember that it sometimes falls to the lot of the plain doctor to effect a cure of the *patient* by restoring the general functional health, even where a specialist has had full swing and failed to cure the *disease*. So, if you will be a specialist, try not to forget what you used to know as a plain doctor."

Honours to Army Medical Officers.

THE Queen has been pleased to grant to the following officers of the the Army Medical Department Her Royal licence to accept and wear the insignia of the several classes of the Orders of Osmanieh and the Medjidie which His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan, has been pleased to confer upon them, in recognition of their distinguished services before the enemy during the late campaign in Egypt:—
Second Class Medjidie: Deputy Surgeon-General and Local Surgeon-General J. A. Hanbury, C.B. *Third Class Osmanieh*: Deputy Surgeons-General J. Ekin and Colvin Smith (Madras); Brigade-Surgeons W. G. N. Manley, V.C., and J. A. Marston, M.D. *Third Class Medjidie*: Brigade-Surgeons O. Barnett, C.I.E., E. G. McDowell, E. McGrath, and R. W. Jackson, C.B., with Surgeons-Major J. H. Beath and G. S. Davie. *Fourth Class Osmanieh*: Surgeons-Major J. Dallas Edge, M.D., G. W. McNalty, M.D., and W. N. Keeper (Bengal).

Treatment of Placenta Prævia.

DR. HOFMEIER, Assistant Physician at the Gynaecological Department of the University Klinik, Berlin, met with forty-six cases of placenta prævia in a little over one year. His experience has led him to reject the expectant plan of treatment, and we will not withhold our congratulations on his arriving at such a happy decision. Thirty-seven out of the forty-six cases were treated actively from the moment operative treatment was practicable. He did not wait till the cervix was *sufficiently dilated*. The bi-manual method of turning was employed thirty times; in three of the cases a foot was already down; three times internal version was performed; and in one forceps were used. It was observed in every case that the hæmorrhage ceased whenever traction was employed on the fœtus. He considers that the principle of

earliest possible intervention should not be departed from, even when the cervix is contracted and the external os tolerably small. In these cases the finger should be thrust through, regardless of placenta, and a foot drawn down. When the placenta is centrally situated, or whenever the hæmorrhage is copious, the danger to the mother is so great that danger to the child should not be brought into comparison with it. When once a foot is down, however, there is no longer any need for haste. On the contrary, too much speed may now bring about the very danger it has been the attendant's main object to escape from. Thus rapid delivery now—too rapid delivery—might, and would, cause laceration of the cervix, and this, in the bruised and wounded condition of the part would undoubtedly be the cause of serious, harassing, and, perhaps fatal hæmorrhage. For these reasons, then, extraction, after a foot is once down, should be slow. Hofmeier is in the habit of injecting subcutaneously 0·4 grmm. of ergotine, and after delivery syringing out the uterus with a 5 per cent. carbolic solution. The results obtained were brilliant, and were just what might be expected where early and rational treatment is adopted. One death only occurred in the thirty-seven cases treated in the above manner, and in the fatal case death took place on the seventeenth day from phlegmon and phlebitis; she had, moreover, been treated by tampons for twenty-four hours before labour. These results compare well with those usually met with in placenta prævia, viz., a mortality of from 30 to 40 per cent. Of the thirty-seven children, seventeen were already dead when delivery was commenced. Of the remainder, six died during delivery—three of them were premature children, and three died in consequence of the perforation of the placenta. Perhaps Dr. Hofmeier is hardly fair to himself. The danger to the child from deprivation of oxygen is in placenta prævia so great that it is more than probable that a larger proportion of infants would have died had any other method of treatment been followed out.

Proposed Students' Club for Dublin.

WITHIN the last fortnight a general meeting of students of the School attached to the Royal College of Surgeons of Ireland was held in the large lecture theatre to consider the desirability of forming a Students' Social Club in connection with the School. There were present Professors Mapother, Stoker, Roe, Stokes, and Cunningham; Dr. Thompson, Dr. Myles, Dr. Knott, and Dr. Jacob. Professor Cunningham occupied the chair. Professor Roe said for a long time he had thought that a club of the kind proposed would greatly add to the comfort of the medical student. It was proposed to get some place where students could meet together to have luncheon, to smoke, or read the papers. He would like to hear the opinions of some of the senior students on the subject. Professor Cunningham then referred to the Students' Club in Edinburgh, which had luncheon and dining, reading and smoking rooms, a study and lavatory, a post-office where letters are received free of charge, and a lodgings' register. After some discussion, in which several students took part, as to whether students from other schools should be permitted to participate in the management of the club, it was resolved that a committee of ten should

be elected, six of which should be students of this school, the remaining four to be elected by other schools. The following students of this school were elected on the committee of management:—Messrs. O'Brien (1st year), Fitzgerald, McKay (2nd year), Kennedy, Greig, and Sprent (3rd year). F. J. Greig was elected honorary secretary. Professor Cunningham said it should be a matter of honour to every man present to push on this club. He would speak for his colleagues on the council, who, he was sure, would aid them in the matter. A vote of thanks was then passed, thanking Dr. Cunningham and the other professors for attending the meeting.

Shortening of Round Ligaments for Cure of some Displacements of the Uterus.

AN important paper was read on the above subject on the 23rd ult., before the Liverpool Medical Institution, by Dr. William Alexander. Considering the great number of cases of prolapsus of the uterus and retroversion that are practically incurable, Dr. Alexander sought for some other method of treatment that had at least the one merit that it had not already proved its uselessness. After many operations and investigations on the dead body, he decided finally to try the effect of cutting down on the inguinal ring, seizing the round ligament, drawing out the "slack," and then, after ascertaining the exact redression of the uterus, fixing the ligament thus tightened in its new situation. The results obtained were very encouraging, and in some earlier instances have, after a lapse of six or eight months, lost none of their encouraging character. His first paper on the subject was published in the *Medical Times and Gazette* of the present year. The method certainly shows a fertility of resource that is deserving of success. In the present stage, it is too early to say that the operation has proved anything; but bearing in mind the impossibility of retroversion or prolapsus occurring simultaneously with anteversion, and the apparently undoubted power that is hereby given us of producing anteversion artificially, and that the latter affection is much less serious and unbearable than either of the former—bearing all this in mind, we may say that the new operation appears likely to enable us to choose the lesser of two evils in a class of distressing cases in which hitherto we have had no choice at all. The idea is not altogether new, but was very nearly practised by Koeberlé, of Strasbourg, in 1869, when he attempted to attach the broad ligament to the abdominal wall in a case of retroversion.

THE annual death-rates per 1,000 in the large towns last week, from diseases of the zymotic class, were:—From scarlet fever, 1·4 in Birmingham, Sheffield, and Newcastle-upon-Tyne, and 1·5 in Liverpool; from measles, 1·6 in Hull, 2·4 in Cardiff, and 5·3 in Sunderland; from whooping-cough, 1·4 in Plymouth, and 1·6 in Preston; and from "fever," 1·3 in Hull, 1·4 in Brighton, and 1·8 in Sunderland. The 44 deaths from diphtheria included 21 in London and 9 in Glasgow. Small-pox caused 4 deaths in London, and 5 in Newcastle-upon-Tyne, but none in any of the other large towns.

Supposed Suicide of a Medical Man.

WE are sorry to learn from Howden-le-Wear, Durham, of the death of Mr. C. H. Wainwright, M.R.C.S., of that village, who was found in an unconscious state against the door of his bedroom a few days since, having, as it subsequently transpired, taken an overdose of laudanum. Medical aid was immediately procured, and the usual remedies applied, but notwithstanding the efforts of three neighbouring practitioners he died in a few hours afterwards. Mr. Wainwright was the parochial medical officer of Howden, and as a charge of neglect of duty while under the influence of drink had been preferred against him, it is supposed he wilfully took his own life, rather than submit to the disgrace which an inquiry entailed.

Money Value of Sanitary Precautions.

IN these days of active sanitation one looks back with pain on the accounts we have of the hospitals of London and Paris towards the close of the 17th century and for years after. That able statistician, Sir Wm. Petty, shows that the deaths in Guy's and St. Thomas's Hospitals were about 13 per cent. on the admissions; in La Charité, in Paris, 14 per cent.; while in the great Hotel Dieu it reached 26 per cent. Now he also shows that, calculating the value of a life at that of an Alger slave in that day, £60, the deaths in the Hotel Dieu beyond those which occurred through natural necessity, and being the result of mismanagement, cost France a total of £210,360. He further calculated that a proper expenditure of £3 per bed occupied during the year, amounting *in toto* to £12,501, would have saved France annually £197,859. Here is matter for consideration by our corporations and boards of guardians. The adage *occulte veniente morbo* applies to their functions as well as to those of the physician, and a wise outlay of money to meet expected epidemics is true economy. What would have been the saving to the ratepayers of Dublin if at the outbreak of the small-pox epidemic the guardians had promptly provided full and fitting hospital accommodation, houses of recovery, and house-to-house vaccination! and had the municipal authorities been more active in the removal of nuisances, the cleansing of houses, and the other various duties of a sanitary authority, over which there was expended so much long-winded oratory!

DR. MANSON FRASER, one of the resident medical officers at the Metropolitan District Fever Hospital, is the Howard Medallist of the Statistical Society for the present year.

THE new (Wayneffe) Chair of Physiology in Oxford University has been filled by the appointment of Dr. J. Burdon Sanderson, F.R.S. This Chair is the first to be filled under the new arrangements following the Report of the University Commissioners.

AN anti-vaccination riot took place at Leicester on Friday at a sale of goods seized by the police for non-payment of vaccination fines from six houses. The chief constable and about forty policemen were present in the sale-yard to protect the auctioneer; but they were

overpowered by the crowd, and some of the furniture offered for sale broken to pieces, while the auctioneer was pelted with Cayenne pepper and missiles. Resolutions were passed condemning both the proceedings and the Vaccination Act.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 24, Bombay 24, Madras 34; Paris 23; Geneva 25; Brussels 20; Rotterdam 21; The Hague 23; Copenhagen 18; Stockholm 20; Christiania 14; St. Petersburg 39; Berlin 22; Hamburg 19; Dresden 22, Breslau 31, Munich 25, Vienna 23, Prague 32, Buda-Pesth 22, Trieste 25; Rome 20; Naples 25, Turin 18, Venice 23; New York 25, Brooklyn 20, Philadelphia 18, and Baltimore 23.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE CLASSES IN THE UNIVERSITY OF EDINBURGH.—The classes in the University are becoming so large as to seriously impede the work of education, and in one of them, the chemistry, the noise is so constant and loud as to prevent those students who are anxious to learn from hearing the lecturer.

THE EYE DISPENSARY, EDINBURGH.—The Trustees and Governors of the Eye Dispensary of Edinburgh have appointed Mr. George A. Berry, F.R.C.S.E., at present Assistant Surgeon, to be Acting Surgeon, in room and place of Dr. Argyll Robertson, resigned.

THE SPREAD OF TYPHUS.—Dr. James B. Russell, medical officer of health for Glasgow, in his report, submitted last week to the authorities, traced in a very instructive manner the propagation of typhus from one centre to fourteen distinct cases. He noted that a girl of 13, who is somewhat weak both in mind and body, became ill on 25th September, but the nature of her disease was not at first suspected. From that date the house must have gradually become saturated with typhus. Of the 11 inmates 7 have had typhus, and 1 has died. Three houses, one on the same stair, the others on two different stairs opening off the same court, were infected, and one case removed from each to hospital. Another house was infected in Old Wynd, the appearance of a married daughter belonging to the original family making a call while Dr. Russell was in the house being enough to show the track of the infection. One of the girls in the original house worked at paper box-making; she was at work until she sickened on the 14th October. Two girls who worked beside her—living, one in Anderston, the other on the south side of the river—were seized within the next fortnight. The nurse who received one of the first patients removed to hospital, and assisted in undressing him, spoke of the offensive animal odour of their clothes. She was nurse of the enteric fever ward, to which he was sent for diagnosis. She sickened with typhus in six days after, and died last Saturday. So that to this centre in Stockwell is traceable 14 cases of typhus in all—seven in the house, and seven in seven separate points in the city, and two deaths. The transference of the disease in the wearing apparel of the girl to her workshop is only a recent illustration of a feature of typhus which Dr. Russell has seen illustrated by similar cases in former years. People living in overcrowded houses and whose personal habits are uncleanly are magazines of such disease as typhus. There

fore, if you turn them out with their wearing apparel upon them to disinfect the house, they carry the disease into the house where they receive temporary shelter, and return with it to the house which has been disinfected.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 18th inst., was 89, and the death-rate 20 per 1,000. Diseases of the chest accounted for 47 deaths, and zymotic causes for 6, of which 1 was due to fever and 3 to scarlatina, the intimations of these diseases being respectively 13 and 53.

EDINBURGH HEALTH SOCIETY.—The opening lecture of the series, to be given under the auspices of the Health Society of Edinburgh in the present winter was delivered by Professor Douglas MacLagan, on the 18th inst., in the United Presbyterian Synod Hall. The Earl of Rosebery presided, and there was a large attendance. Professor MacLagan, who dealt with the subject of ventilation, spoke during great part of his lecture of the more elementary facts upon which a knowledge of the subject was founded, his remarks being chiefly addressed to the working classes.

GLASGOW DEATH-RATE.—The death-rate of Glasgow for the week ending with Saturday, the 18th inst., was 29 per 1,000 per annum, as compared with 24 for the previous one. For the corresponding periods in 1881, 1880, and 1879 the rates were 23, 22, and 23 respectively.

LEGACIES TO PUBLIC INSTITUTIONS.—The trustees of the late Miss Jane Mudie have, through their agent, handed over the following legacies:—To the Royal Infirmary, Edinburgh, £150; the Royal Blind Asylum, Edinburgh, £100; the Dundee Infirmary, £150; the Building Extension Fund of the University of Edinburgh, £100.

DUMFRIES.—THE INFIRMARY DIRECTORS AND FEVER PATIENTS.—A conference was held on the 20th inst. between the infirmary directors and a deputation from the local authority with regard to the limited accommodation which at present exists for the fever patients in the Infirmary. The whole case was remitted to the Police Commissioners, when it was resolved to take no action until Dr. Gardner's report was received. The medical officer was instructed to report whether there had been such a prevalence of fever as called upon separate action being taken by the local authority.

THE MEDICAL PROFESSION AND THE COMPULSORY NOTIFICATION OF DISEASES BILL IN GLASGOW.—A meeting of the medical profession of Glasgow and neighbourhood was held in the Faculty Hall on the 24th inst. for the purpose of considering certain clauses in the Police Bill. Dr. Scott Orr, President of the Faculty, presided. The Chairman, in opening the proceedings, said that last spring the question of the notification of infectious diseases had engaged the attention of the profession, and it was the unanimous feeling that the responsibility of notification should be placed on the householder. Since then this Police Bill had been promulgated, which the Town Council were now engaged in discussing, and which they seemed inclined to push through with undue haste. He noticed, however, that a question had been asked last night whether the Lord Advocate was prepared to formulate a bill for the whole country, and his answer was that he expected to be able to do so next session. This might possibly bar the discussion now going on, and the perceptible haste with which this bill was being pushed forward. Dr. Fergus moved the first resolution. He said this Glasgow Police Bill was being hurried forward with undue haste, and he expected that after the declaration of the Lord Advocate the Town Council would withdraw the bill in the meantime. He distinctly objected to the duty of reporting infectious diseases being laid upon the medical attendant. Dr. Morton,

in seconding, said it would be a most iniquitous law, and a very injurious one, to place a medical man in any position which would render him obnoxious to his patients, or render him suspected, and there could be no doubt it would lead to that concealment of disease which prevailed too much already, and led to the spread of disease and increased mortality.

Literature.

THE INTERNATIONAL ENCYCLOPÆDIA OF SURGERY. (a)

A WORK so comprehensive and pretentious in its scope as this, naturally invites severe critical examination. It assumes to be, not merely a system of surgery, but an exposition of the most received opinions of the leaders of surgery and its allied sciences in all parts of the world. To say that the task of issuing such a *magnum opus* could not be performed in such a fashion as to satisfy all persons, is to utter a truism; but we may fairly state that the volume before us is as near an approach to what excellence is possible in the way of so representative a performance as we could hope for—in a first edition, at all events. Owing its birth and utterance to an American source, it is naturally enough tinged by its origin, and owes an amount of its contributions to American sources which is perhaps rather in excess of what might be desired, having regard to its assumption of internationality, and to the number of distinguished surgical writers who relatively date from the Old World and from the New.

In one respect it excels any previous work with which we are acquainted, namely, in its extremely comprehensive character, including as it does a number of topics which have heretofore been relegated to the domain of special works, but which are properly treated of in a book on general surgery when, like the present one, it is encyclopædic in character. In type and paper it leaves little to be desired, and the illustrations, though rather rough and coarse, are expressive and numerous, although we think that when but three coloured plates are included in the present volume, the last of them might have been devoted to a more suitable and necessary subject than the delineation of stumps, which could have been shown as well by a woodcut.

Of the first article, that on Disturbances of Nutrition, it is only necessary to say that it is written over the name of Stricker, to convey that it is a model of composition, learning, and research such as that great professor is likely to have produced. The article on Inflammation, too, is exceedingly good, although it comes from an author who is better known in connection with a special subject than a general one, and Professor Van Buren is to be congratulated upon being perhaps the first writer in a comprehensive work on surgery who has treated the antiseptic question in connection with the general one of inflammation, and has treated it well. His references to the researches of Koch, Burdon Sanderson, and others, are concise and clear, and one of his paragraphs we extract with pleasure from a book the editor of which shows evidences of an unhappy scepticism on the subject of one of the greatest advances which surgery has made in this century: "It may seem out of place in this connection to speak of the practical results of antiseptic surgery, but, in the present attitude of this important question the most available evidence as to the truth of the theory is furnished by the very considerable degree of success which has been attained by the antiseptic method of treatment. In striving to reach a correct estimate of micro-organisms as exciting causes of destructive inflammation, it is proper, therefore, to recognise that clinical experience tends to prove that the means which have been found hostile to the development of these organisms are also growing steadily in reputation as remedies for the destructive phases of inflammation." Again, later on: "Judging from results alone, without attempting a decision as to the theory on which it is based, placing himself on the legitimate ground of intelligent empiricism, and following the plan which promises the

(a) "The International Encyclopedia of Surgery: a Systematic Treatise on the Theory and Practice of Surgery, by Authors of various nations." Edited by John Ashhurst, Jun., M.D., Professor of Clinical Surgery in the University of Pennsylvania. 6 Vols. Vol. I. Macmillan and Co. 1882

most benefit to his patient, the surgeon of to-day is forced by the logic of facts to adopt the method of Lister."

In considering, in a later part of the book, the enormous fatality of the amputations recorded by Mr. Ashhurst in his own practice, we could not but wish that he might take the lesson of these paragraphs to heart and reform his practice by following the teaching of Lister. The introduction into this article of the topics of Diet and Nursing is commendable, and is a part of that comprehensiveness of detail in the whole work which we have previously mentioned.

The articles on Erysipelas, Pyæmia, and Hydrophobia are all concisely and well written, but we fail to see why "Ashhurst" should be given as the authority for the treatment of erysipelas by limited incision, which is well known to have been first taught by Dr. Copland Hutchison.

The name of Dr. Butlin is enough assurance that the subject of Scrofula and Tubercle is well and carefully treated. While we agree with him on the excellent effects to be gained by the use of Volkman's spoon for scraping the cavities and sinuses connected with diseased glands, we could wish that his experience had allowed him to express a more definite opinion in favour of the extirpation of enlarged glands, a proceeding we have generally found most advantageous.

The article on Rachitis is one which will repay careful study; and that on Scurvy, by Surgeon-General Wales, is all that could be expected from an authority of his eminence.

The "Reciprocal Effects of Constitutional Conditions and Injuries" are treated by Prof. Verneuil in a careful and logical spirit; and the essay on the "General Principles of Surgical Diagnosis," by Dr. Hayes Agnew, is exact and comprehensive, and is an excellent addition to the logical literature of surgery.

Dr. Mansell-Moullin contributes a carefully-written treatise on "Shock," and Dr. William Hunt one on "Traumatic Delirium."

The article on "Anæsthetics and Anæsthesia," by Prof. Syman, is very comprehensive and good. He treats the gradual recognition which ether, as compared with chloroform, is receiving in England, with even more delicacy than we could expect from an American writer, having in recollection the bitter jealousy as to priority of adoption of anæsthetics which has existed between the two countries.

"Operative Surgery in General" is the title of an introductory treatise by Dr. J. H. Brinton, which contains much excellent and novel matter relative to the qualifications of a surgeon, the use of anatomical knowledge, preparation for an operation, and other cognate topics. Dr. Brinton is to be congratulated for having produced an article both ethical and surgical which is well worthy of study.

The article on "Minor Surgery," by Dr. Hunter, in point both of illustration and treatment, is equal to the high reputation which American authors have already achieved for their writings on this important branch of surgery.

Prof. Johnston has produced an excellent article on "Plastic Surgery," which deals with the principles of the subject, leaving its application in individual cases to be treated of subsequently in particular regions. His account of skin-grafting is particularly excellent, but would be more perfect if it contained some reference to the process of skin-transplanting, which has of late received considerable attention, particularly in cases of deformities of the eyelids. No treatise on plastic surgery is perfect without a notice of the process of sponge-grafting, which is yielding such good results and receiving such close investigation at present; surely the discovery of this process by Prof. Hamilton, and his subsequent observations upon it, are known across the Atlantic.

The article on Amputations, which closes the present volume, is comprehensive, highly illustrated, and in many respects good, but we are compelled to take exception to many points in it. The editor, who is its author, is evidently not a follower of the antiseptic system, and to this perhaps we may attribute his statement by implication that compound fractures into the knee and ankle joints are, *ceteris paribus*, likely to require amputation. We rejoice to think that in England, since the advent of Lister, at all events, such teaching cannot be received. Similarly we protest against the statement immediately following, that compound dislocations of large joints "almost always" require excision or amputation. In speaking of the methods of controlling hæmorrhage in amputation through the hip-joint, no mention is made of Davy's lever, which is surely the most excellent improvement in that operation which has ever been effected!!

We dissent from the statement that Butcher's saw is

"almost indispensable" in excision of the knee. We believe that the experience of most surgeons is that the flat surfaces which it is desirable to form in that operation can best be made with a common amputating saw. The forceps depicted in Fig. 137 is not Nunneley's, but Dieffenbach's well-known "bull-dog" forceps. The author's commonplace arguments against antiseptic surgery we put aside, merely referring to the fact that in 100 cases of amputation which he publishes he had 28 deaths!! Explain this as he may, the fact remains, in spite of special pleading. In speaking of the dressing of stumps, Mr. Butcher is named as the authority for permitting the wound to glaze before closing it, a proceeding of course inimical to antiseptic measures, and which, if ever good, dates long before the time of Mr. Butcher.

The table of amputations through the hip is of particular excellence, numbering as it does no less than 633 cases.

The illustration of the skeleton of a finger on page 631, designed to guide the surgeon in amputations through the phalangeal joints, is particularly useful, as are the portions of the article dealing with the questions of the adaptation of artificial limbs, matters which have been too much relegated to the mechanist and too little considered by the surgeon. We are glad to find the experience of Mr. Ashhurst on one point in particular coincident to our own, namely, the growing estimation in which he holds the circular as compared with other methods of amputation.

NEW HANDBOOK OF DOSIMETRIC THERAPEUTICS. (a)

THIS is a book to make the earnest therapist sad. We have heard enough of new systems of medicine, and might have hoped that there would be no necessity to translate from so generally known a language as French the enthusiastic declarations of the aged professor who claims the discovery of "dosimetry." This system may be said to consist mainly in the administration of doses ready prepared in the form of minute granules or globules. Both author and translator insist that these cannot be trusted unless prepared by one French pharmacist—a slur alike on his countrymen and on pharmacutists throughout the world. "Jugulation, or cutting short acute diseases, is one of the greatest feats of dosimetry." But this feat consists in giving repeated doses of aconite, a method practised long before Dr. Burggraave. By the way, we hope such French words as jugulation and others used in this book may be avoided by any who take up with dosimetry. But there is reason to hope this form of dosimetry may die a natural death. We have no objection to symptomatology being assigned a prominent place, but we cannot be pleased to see it so exalted as to render physiology and pathology despised; neither can we expect a cordial reception for a "system" which starts like homœopathy, by nick-naming rational medicine Allopathy. Nor can we commend an author's taste who takes up this jargon and says, "Allopathy weakens the patient's system by bleedings, purgings, sweatings, and fastings." Surely, Dr. H. A. Allbutt has not so learned medicine as to believe this description just. Howbeit, we do not wish to raise a question of systems here. All we would say is, that others preceded Dr. Burggraave in preparing pilules, granules, &c., of powerful drugs in definite doses, and both English and American chemists have long supplied all the materials for the practice of such a method. Dr. Allbutt is possessed of the enthusiasm of a new convert, and assures us that when dosimetry is universal, "there will gradually begin to disappear all those organic diseases which now desolate the race." Are we to presume that death is an unknown event in his own practice? Perhaps the assertion may be left, for universal slavery to so empirical and unsubstantial a system is happily as little likely to occur as the disappearance of organic disease. Dr. Burggraave mentions in his preface that he has devoted a long chapter to uroscopy. Our readers may judge of its value by the following indications:—

Fat in the Urine.—"In this case the nerve tonics must be given, such as arseniate of strychnine. Fat in the urine may also depend upon a fatty degeneration of the kidneys. Tonics must always be administered."

Sugar in the Urine.—"I have stated that sugar in the (a) 'New Handbook of Dosimetric Therapeutics.' By Dr. A. I. Burggraave. Translated and edited by Henry Arthur Allbutt, M.D.C.P., Ed. London: Bogue. 1882.

urine, or in the tissues (diabetes mellitus, or non-mellitus), indicates a fault of combustion, which requires the nervines, phosphoric acid and arseniate of strychnine, together with saline regimen."

If such crudities as these should be the sole outcome of what is so loudly vaunted as a new era in therapeutics, we feel no inclination to discard rational medicine and the allied sciences, for the purpose of accepting as final truths the absurd vagaries of the Belgian Emeritus Professor of Surgery.

LETT'S MEDICAL AND OTHER DIARIES.

THE well-known time-saving and memory-helping publications annually issued by Messrs. Letts, Son and Co. require only a brief notice to ensure their being once more welcomed by those to whom they are addressed. It is impossible, indeed, to refer to a tithe of the forms under which this enterprising firm issues its productions, even those designed for professional uses only, making up an imposing display. We may mention, however, as of especial value to practitioners, *Letts's Medical Diary and Visiting List*, which combines all the requirements of a visiting list, with a conveniently-arranged diary, list of poisons and their antidotes, therapeutical equivalents, hypodermic injections, professional fees, and the necessary space for ordinary entries of engagements, money columns, &c.

Letts's Appointment Diary will be found a most useful pocket companion for ordinary purposes; and nothing can be obtained for narrative work better than the office diaries of this firm. These serviceable works are produced in every style of binding, and at prices to suit all purchasers, and are in every respect fully deserving of the confidence universally accorded to them.

THE DUBLIN OUTRAGE.

THE man Dowling, or Dooley, who is in custody for the murder of constable Cox in the Abbey Street outrage, lies in Jarvis Street Hospital under the care of Dr. Cranny. He has received a bullet which entered near the middle of the collar bone, travelled towards the shoulder-joint, where it was deflected downwards and passed out through front of the upper arm.

A second shot struck his right radius close to the wrist and passed through it. In addition he received a blow on the right parietal bone, which is believed to have been fractured. The prisoner is closely guarded.

The murdered man Cox has been removed from the hospital to the Morgue, where a post-mortem examination was made by Mr. Thomson, of the Richmond Hospital, and Dr. Egan. The inquest was commenced on Monday last, and will be resumed to-day (Wednesday), when the result of the post-mortem will be made known.

Correspondence.

THE ACADEMY OF MEDICINE OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I observe that in your last issue, in describing the election of the officers of sections in the new Academy of Medicine, you say, "In the Obstetrical Section the contest was hottest, there being two candidates for the Presidency, Drs. Denham and Kidd," and I beg to assure you that contest was without my knowledge or concurrence. I absolutely did not know till the day after the election took place that there had been a contest, or that there had been a wish on the part of Dr. Denham or any of his friends that he should be elected to the office. If I had been aware even that he would accept the office, I would not have allowed my name to have been put forward: instead of an opponent I should have been one of his warmest supporters, and I now rejoice in his having been elected. He was one of my earliest teachers: as

a student I lived in his house and received the greatest kindness from him, and we have ever since been friends. By his seniority and by his energetic support of the movement he was entitled to the honour, and I greatly regret that that honour should have been in any way alloyed by there having been a contest of any kind. I grieve that no one, influenced either by zeal for the welfare of the Academy or kind feeling towards Dr. Denham or myself, felt impelled to inform him or me that a contest was impending, for assuredly if we had known of it a contest would not have occurred between us. The way that this contest occurred was this: Soon after the Dublin Obstetrical Society had consented to merge their existence of nearly half a century in the Academy, and become a section of it, the Acting Secretary of the Provisional committee who were engaged in getting up the Academy asked the Secretary of the Obstetrical Society to nominate officers for election. The Secretary of the Obstetrical Society called a meeting of the Council, and they, at what was, I believe, a full meeting, passed a unanimous resolution nominating me for the presidency of the section. This resolution the Secretary communicated to me, asking could I accept the office, and I feeling very much gratified that the Council of the Society with whom I had so long worked should wish to have this honour conferred on me, unhesitatingly said I would gladly accept it. The nomination and my acceptance of it were officially communicated to the Provisional Secretary of the Academy, whereupon he wrote to me saying I had been nominated both for the Presidency and for the Council, and asking which I could accept, and I replied as I had previously done to the Secretary of the Obstetrical Society.

The Provisional Committee, as I am informed, thought it right, notwithstanding having applied to the Council of the Obstetrical Society to do it, to nominate other candidates for the various offices and to use all their influence to secure the election of their own nominees. In this they succeeded; and while I congratulate them on having obtained so excellent and worthy a President as Dr. Denham, I must again express my regret that they did not communicate their wish to me, when I should certainly have done nothing that could in any way lessen his pleasure in accepting the office.

I am, &c.,

GEORGE H. KIDD.

58 Merrion Square, Nov. 25, 1882.

THE TREATMENT OF STRICTURE AND OF COMPOUND PALMAR GANGLION (KEETLEY'S "INDEX OF SURGERY").

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your notice of my "Index of Surgery" your reviewer writes:—

"Although this industrious compilation contains a great deal of really valuable information on surgical matters, yet errors of a grave nature are easily to be discovered in it. We may point, for example, to the treatment recommended for the relief of that serious surgical condition produced by stricture. No student could possibly be benefited by being directed to transform a bulbous bougie into a filiform one by the simple process of 'snipping off' the bulb. Again, the treatment by trocar and canula of compound palmar ganglia will not recommend itself to experienced surgeons, who are familiar with the dangers that attend operative interference with this disease."

Concerning the merits or faults of my book I am not going to write a word; but, in giving the above two specific examples of "grave errors," your reviewer has raised two surgical questions, with respect to which I—not as the author of the "Index of Surgery," but as a surgeon—beg leave to be permitted to come to an issue with him.

The process of snipping off the bulb of a "bougie-à-boule" is mentioned by me in a page and a-half of suggestions, headed in italics, "Rules for Managing a Stricture Impermeable to Ordinary Means," and I have seen this particular plan successfully employed in such cases both by Mr. Furneaux Jordan and myself. Grave error No. 1, therefore, resolves itself into a hint dropped in the course of seven and a-half pages devoted to the treatment of stricture of the urethra, and based on practical experience.

With regard to the treatment of compound palmar ganglion, I assert that the question of trocar or knife is a minor one. I mention both in my book, and recommend neither one nor the other. But I distinctly recommend the

antiseptic treatment, and that I hold to be the main thing. With it, in competent hands, the dangers of operative treatment of compound palmar ganglion disappear. And what non-operative treatment is really worth trying for this affection? So much for grave error No. 2.

I am, Sir, yours, &c.,

O. B. KEETLEY.

London, Nov. 25, 1882.

LIMITATION OF OVER-POPULATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your excellent article of November 22nd on the above subject, will, I doubt not, give rise to many an interesting debate. The poverty caused by large families in the United Kingdom is the main cause of both excessive infantile mortality and early death among adults, for I find that the average age at death, among the richer classes in England and Wales, is now as high as 55, whilst the age at death, among the artizan class, is only about 29. In Paris, in 1877, I found that 100 distinguished members of the Academy of Medicine had only had 174 children; whilst at the Metropolitan Free Hospital, Whitechapel, London, 100 poor women had had 720 children. In Dublin, as Dr. Cameron admits, poverty is the main cause of the terribly high death-rate, and Mr. J. S. Mill used to maintain that people with large families in Europe should be sent to Coventry.

Yours, &c.,

Nov. 22nd, 1882.

M.D. Lond.

HINTS OF EXPERIENCE.—II.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—There is an observation which I made very early in my dispensary practice which seemed to be confirmed by later practice—namely, it appeared to me that there was a kind of periodicity in all disease, or in the vital conditions of all persons. It has appeared to me that there is a sort of wave-like exacerbation of symptoms, and that in many cases this is so marked that the practitioner may predicate when the patient will be worse, and prepare for the conditions thus foreseen. Even in purely surgical cases the patient manifests this periodicity; he flushes at the same period, and there is a kind of punctuality in his pallor. Constantly I have noticed that patients grow worse at a particular hour of the night or morning, and at a corresponding hour they die, if the case be fatal.

In cases of gall-stone, or passage of calculus down the ureter, the attack is constantly recurrent at the same hour or within the same number of hours as between the first and second attack. The effects of great venery regularly appear at the twenty-fourth hour afterwards. In fevers this periodicity has been long recognised; I venture to think that it is more or less marked in all disease. I should be glad if this idea be tested by wider experience, though I have no doubt of the fact in my own mind; but one man's experience is, after all, a comparatively limited field of observation in a science like that of practical medicine.

The occurrence of death more frequently at particular hours, rather than at other hours, is a fact well ascertained, and has found no explanation. May not the establishment of this theory of periodicity be a step towards such an explanation?

Why do labours most frequently occur during the night? That few deliveries take place in the day-time is a matter of common observation. But has it been noticed that, for some reason or other, and long before any symptoms of labour set in, the woman has a passion (so to speak, because the instinct is so strong) to clean up the house, or to rearrange her room, or to do that which seems in the bird a haste to finish the nest before she begins to lay? If this be found to be a common experience it shows a singular alliance between the human species and the lower animals; if it has not hitherto been noticed, I beg my professional brethren to test the fact by their experience. Of course, it may be argued that labour supervenes as the result of the exertions of putting the house in order, but this seems to be met by the impression produced on my mind by women of the upper classes, who did not themselves

make any special exertions, but nevertheless required the servants to have "a regular cleaning down" and re-arrangement of furniture within a few hours before the confinement. If such an instinct be always manifested at such a time it is a very curious fact. There is another aspect of periodicity in uterine action also on which I hardly need comment here, but which seems to bear out my theory.

I shall be glad to hear of any experiments or observations to confirm or contradict my own, because, in a profession like that of medicine, we should be cautious not to commit the fallacy of drawing a general inference from a particular case or series of cases. When I was a student many things were received as truths beyond dispute, but time and further observation have shown those assertions which were formerly received as indisputable, not only to be doubtful, but untrue. The scientific student will therefore hesitate to draw an inference, lest the cases he has observed may contain some exceptional conditions and thus point to a conclusion which is not a safe guide for future action. Indeed, I am confident that if the replies given to an examiner in 1840 had been given to an examiner in 1880 the student would have been ignominiously rejected. Therefore, *festina lente* should be the motto of all men who practise medicine.

ALTER BROWN.

Obituary.

PROFESSOR PIRRIE, OF ABERDEEN.

It is with sincere regret that we announce the death of this distinguished surgeon, which occurred on the 21st instant. Deceased had been suffering from an internal malady for several months past, and had for nearly the whole of the present year been compelled to abandon his work in the University and in private practice. In the early part of September, the complaint yielding to rest and treatment, became less painful, and after a holiday in the Highlands he was enabled to resume practice to a certain extent. But it was not for long; the disease was still making its insidious progress, and but for a powerful physique and a robust constitution, the end would have come long since. No one understood better than Dr. Pirrie himself of the impossibility of recovery; indeed, this was evidenced by his relinquishing the Chair of Surgery, in the University during the summer, and subsequently by the freedom with which he spoke to his friends of the coming dissolution. By his death Scotland has lost one of her foremost surgeons, and Aberdeen one who might be aptly styled the Father of Surgery in her school. He was the first occupant of the Chair of Surgery in the University of that city, a post which he occupied with unflagging energy and zeal for forty-two years, during which time he devoted himself to the procuration of "specimens" for the education and instruction of his classes, which is probably unique in any of the Scotch Medical Schools. Dr. Pirrie was essentially a self-made man, abounding with that zeal and ability characteristic of men who make a name in the world without inheriting it. By sheer force of character and innate ability he rose from the ranks of a pupil in a parish school to be one of the most honoured and respected of surgeons, not only in Scotland, but throughout the world; and surgeon by appointment to the Heir Apparent of the British Throne; while some eight years ago the University of Edinburgh, his *Alma Mater* in surgery conferred upon him the degree of LL.D., and the Clinical Society of London elected him an honorary member of their body.

Dr. Pirrie was well known in the field of medical literature. His "Principles and Practice of Surgery" has gone through three editions in this country, while the popularity of the work in America may be gauged from the fact that a fifth edition is now in course of preparation in that country. Besides this volume, Dr. Pirrie's contributions to medical journals were frequent and of original merit, and many of his papers have been circulated in pamphlet form. Notably, it will be remembered that his treatises upon acupuncture attracted a considerable amount of attention, and there are many other subjects connected with surgical science upon which, in the course of a long and earnest lifetime, he gave in more than mere fugitive form the results of personal and practical study in the domain of surgery.

In concluding this notice of one of whom the profession was justly proud, we cannot do better than quote the opinion of Professor Struthers, expressed before his class a day or two since. "Dr. Pirrie," he said, "was neither the creature of nepotism, nor the vaunted member of some party whose geese, according to the proverb, are always swans. Meaning to be a surgeon, Dr. Pirrie commenced to teach anatomy as lecturer on that subject in Marischal College, a duty which he discharged for eleven years; and it was no doubt to this experience that he owed that thorough acquaintance with the anatomy of the human body which they all recognised in his surgical teaching, and which stood him in so good stead in the operating theatre. From 1839, when the Chairs of Anatomy and Surgery were first founded, down to almost the day of his death, Dr. Pirrie was, as they all knew, the able, eloquent and successful Professor of Surgery in the University. It is given to few men to have been teachers over half a century, and to still fewer to have, over that stretch of time, maintained the vigour of their teaching—he might almost say to have increased in vigour and in enthusiasm in the work as time stole on, for Dr. Pirrie was not one to become lazy when secured in office, or to fall behind the age either in knowledge or in attention to improvements in methods of teaching. When, with the spirit of the age, the modern wave of demonstrative teaching reached and stirred Aberdeen, as other schools, Dr. Pirrie, instead of, like too many men who have passed the middle of life, crying up the past, took it up heartily and vigorously, and they all knew how he enjoined and enforced the importance of the demonstrative method of teaching surgery."

Dr. Pirrie is no more, but his name will be remembered with affection by hundreds who have been brought under his influence, and by all who honour an upright life and a genius born in the few.

DR. RICHARD CROSS, OF SCARBOROUGH.

THE death of Dr. Richard Cross, of Scarborough, which occurred on the 18th inst., removes one who was at once a prominent figure in the medical world and a universally respected member of society. For long past Dr. Cross had been ailing, a painful affection of the knee, caused originally by accidental injury, having troubled him to a grievous extent; eventually the limb had to be amputated, and though the immediate shock of the operation, which was performed by Mr. Jessop, of Leeds, seemed to be recovered from, the patient survived only about twelve hours after it. The deceased physician was born in 1818, and after a successful hospital career took the L.S.A. in 1839, and the M.R.C.S. Eng. in the year following. In 1852 he graduated M.D. of St. Andrews University, and in 1881 received the distinction of Fellow of the College of Surgeons. Locally, Dr. Cross was esteemed in the highest degree, the numerous public and honorary appointments held by him from time to time testifying to the admiration and respect generally felt for his character and attainments. This was well shown also at the funeral, which was little less than a public ceremony, and was attended by a very numerous company of mourning friends. The whole proceedings were eminently impressive, and demonstrated the grief felt by the community at the death.

DR. O'FARRELL, OF BOYLE, CO. ROSCOMMON.

WE regret to announce the death, last week, of Dr. Harward O'Farrell, of Boyle, co. Roscommon. He was an old and highly-esteemed practitioner throughout the county in which he resided. He obtained the M.D. of Edinburgh in the year 1835, and was a Fellow of the Irish College of Surgeons, and a J.P. for his county for the last 20 years. He was medical officer of Boyle workhouse and Boyle No. 1 dispensary district, and he was also acting surgeon of the Roscommon Militia.

Life Assurance.—The 58th annual report of the Clerical, Medical and General Life Assurance Society, just to hand, reveals the important and satisfactory fact of the increased attention which life assurance is receiving at the hands of the general public, and especially the professional portion of it. This Society's business is of peculiar interest to the medical profession, and the increasing numbers and amounts of assured

and assured upon its books is not only an evidence of the soundness of the office, but of the spread of those principles of foresight for eventualities we have so often striven to impress, and which have been found lacking in many a sad death of recent years. With such names as Sir William Jenner, Sir James Paget, Prescott Hewett, William Bowman, Lionel Beale, &c., upon the directorate the profession is well represented, and may have every confidence in the undertaking. In January last the Directors had the satisfaction of declaring as a bonus the enormous sum of £345,000. The result to the assured was the immediate addition to the assurances of £406,755, in which the whole of participating policies, 9,183 in number, shared. In order to give the Society an increased title to public confidence the Directors have lately made a careful revision of the conditions of its assurances, and provided additional facilities, which may be briefly epitomised as follows:—1st. The practical abolition, so far as concerns the bulk both of new entrants and existing assured, of all restrictions on residence, travel, and occupation. 2nd. Affording increased facilities, by extension, on certain conditions, of the ordinary period of grace, for maintaining policies in force. 3rd. Increasing the facilities for reviving policies allowed to temporarily lapse. 4th. The publication of specimen minimum and maximum surrender values, and thus affording to the assured the nearest possible approach to guaranteed values. 5th. The holding, in the case of a lapsed policy, at the disposition of the assured during a period of two years from the date of forfeiture, of any surrender value which may have attached to it. If to these new conditions be added those previously in operation for lending freely on policies to the extent of nine-tenths of their surrender value, and for paying all claims immediately on proof of death and title, it will be seen that the arrangements of the Society for preserving the equitable rights of its policy-holders under all circumstances are complete, and the Society, already so successful, is now placed in the front rank of liberal and progressive offices.

PASS LISTS.

University of London.—The following is a list of candidates who passed the recent M.B. examination at this University:—

First Division.

Adeney, Edwin Leonard	King, David Alexander
Back, Herbert Hatfield	Maddison, William Thomas
Batterham, John Wilfams	Ferry, Robert
Buxton Dudley Wilmot	Pasteur, William
Collingwood, David	Fratt, Eginald
Currie, Oswald James	Scharlieb, Mary Ann Dacombe
Dakin, William Radford	Shaw, Lauriston Elgie
Dingley, Edward Alfred	Vinace, John Hinks
Fielden, William Eckett	Webb, Malcolm
Haris, Thomas	Wells, Alfred Ernest
Honeyburne, Richard	Wilkinson, W. C., B.A. Syd.
Woodridge, Leonard Charles, D.Sc.	

Second Division.

Adams, William Coode	Murray, Hubert Montague
Bertram, Benjamin	Norvil, Frederic Harvey
Bull, George Coulson Rotins	Pike, Charles Jam
Campbell, Harry	Robinson, Frederick
Carter, Thomas Edward	Roedel, Waldemar Joseph
Ellison, John Clement	Scarth, Isaac
Jewell, Charles Coleman	Shove, Edith
Kirsopp, Thomas	Watkins, Christopher James
Larmuth, Leopold	Woolby, James Balls

Royal College of Surgeons of England.—The following candidates, having passed the required examination for the diploma, were admitted Members of the College on Thursday, November 16th:—

Barnes, Walter S., L.S.A.	MacDonogh, William F.
Cowen, Edw. I., L.R.C.P. Lond.	Mosse, Herbert Ryding, L.S.A.
Donald, James, L.S.A.	Peckett, A. W. C., L.S.A.
Dyson, Herbert Jekyl	Potter, John H., L.R.C.P. Ed.
Harris, Howard, L.R.C.P. Ed.	Rodley, John, L.R.C.P. Ed.
Hull, Walter, L.R.C.P. Lond.	Shapin, Edward Colby
Larder, Herbert, L.S.A.	Underwood, John C., L.S.A.
Llewellyn, James D., L.S.A.	Wigan, Charles Arthur
Maynard, Edward Charles	Woolington, Sidney, L.S.A.

King and Queen's College of Physicians.—At the November examinations the following candidates, having passed the required examinations, received the Licences in Medicine and Midwifery of the College:—

Medicine.

Bolger, James Tandy	Cooper, Robert Edmund
Clancy, John	Garland, John Peter
Cock, Julia	Morris, James Aloysius
	Shes, John Goodwin

Midwifery.

Bolger, James Tandy
Clancy, John
Cock, Julia
Cooper, Robert Edmund

Fisher, Vicars Henry
Garland, John Peter
Morris, James Aloysius
Shea, John Goodwin

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

L. C. D. (Liverpool).—The treatment of empyema is a subject of debate at the present time, but there is a considerable amount of agreement among practitioners respecting the value of free drainage of the pleural cavity through incisions sufficiently extensive for the purpose. Through drainage, however, is to be recommended only in cases where the discharge is offensively fetid, and in which a single opening has failed to afford the required relief. Antiseptic injections must be employed with caution, solutions of salicylic acid or potash permanganate being much safer than carbolic or boracic acids. Resection should be avoided if possible, and particularly in children.

MR. SWANAGE (Edinburgh).—The reference is to Billroth's "Surgical Pathology," Vol. II. After reading your opinion it is quite impossible to form any other conclusion than the one you formulate. It is still, notwithstanding, a matter for further investigation. The facts are easily accessible.

DR. EDWARDS.—The treatment of ulcers by Martin's rubber bandages is worthy of most extended trial. Success is very frequently attained by it after failure with other methods.

PERPLEXED.—The case was one of placenta previa, and hardly deserved the description applied to it.

DISPENSARY MEDICAL OFFICERS AND SUBSTITUTES.—G. S. writes: Could any of your numerous readers inform me if it is usual for the guardians to pay a substitute for dispensary medical officer when he is subpoenaed to the Assizes and may be detained for a week? What would likely be the result if a committee were obtuse in such case, or in the illness of medical officer, absolutely refused to appoint a substitute, and left the district unattended?

[1. It is not usual, as the feeling is that the medical officer being paid for his evidence, ought to pay his substitute. 2. If a medical officer absented himself under compulsion of a subpoena, he could not be blamed; but he should take care to inform the hon. sec. of his committee in good time, and to recommend a substitute, whom—strictly speaking—he is not liable to pay.—ED.]

A FIRST YEAR'S STUDENT.—Your teacher is correct in advising you as he has done. You should follow the suggestions.

MR. C. (Croydon).—The history is suspicious; you will be justified in trying the effect of specific treatment for a time.

A SCOTCH PHYSICIAN must forward his name and address. We do not reply to anonymous communications; and to this rule no exception is possible.

M.D. GLASGOW.—We fail to see the reason for your objection. Each charge was fully substantiated as it was brought; and the fault is rather with the Corporation which neglects its duties than with the critic who exposes such shortcomings.

DR. MATTHEWS.—Many thanks.

SINGLETON'S GOLDEN OINTMENT.—A Provincial Practitioner asks for information, and, if possible, the recipe, of this old-fashioned remedy. The following is, we believe, the correct formula, in preparing which considerable care is required, continual stirring till cold being absolutely necessary:—B Hydrargyri, 3ss.; acid. nitric, 3vss.; butyri (without salt), 3vj.; oleum olivæ, 3iv. Hydrargyrum in acido primum liquis; dum liquor adhuc caleat, butyro et oleo simul liquefactis; misc.

MR. KAY.—The work is in the hands of the reviewer, to whom your letter shall be communicated.

SARTORIUS.—The principle to be followed in all such cases is the same, and it is that of non-intervention. No good can be done by disturbing present arrangements.

R. E. F.—No instance is recorded.

DISSOLUTION OF THE NERVOUS SYSTEM.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—To the title of the second instalment of my article on "Dissolution of the Nervous System," Nov. 27, 1892, I affixed a foot-note altering words in a previous foot-note on page 418. The foot-note on page 418 is correct. For what is called most voluntary is rigidly synonymous with least automatic.

I am, &c.,

J. HUGHLINGS JACKSON.

DR. J. M. (Bow).—Thanks; we shall be glad to receive the paper at your leisure.

DR. W. DONOVAN (Whitwick).—Your letter is unavoidably held over to our next.

THE KING'S COLLEGE DINNER.—We are requested to announce that the Right Hon. Sir John Mowbray Bart., M.P., D.C.L., has consented to preside at the Annual Dinner of Associates and past and present Students, to be held in the College Dining Hall, on January 17th, 1893. Gentlemen wishing to be present are requested to communicate with the Hon. Secretary of the Committee, Mr. H. Courtenay Luck, A.K.C., F.R.G.S., at the College, Strand.

MEETINGS OF THE SOCIETIES.

HARVEIAN SOCIETY OF LONDON.—Thursday, Nov. 30th, at 8.30 p.m., Harveian Lectures: Mr. Henry Power, "On Ophthalmic Medicine and Surgery in relation to General Practice."

ROYAL INSTITUTION.—Monday, December 4th, at 5 p.m., General Monthly Meeting.

Vacancies.

Chipping Norton Union.—District Medical Officer. Salary, £65, with the usual medical fees. Applications to the Clerk on or before Dec. 25th.

Oldcastle Union, Crossakiel Dispensary.—Medical Officer. Salary, £120, and £15 as Medical Officer of Health. Election, Dec. 1st.

Stourbridge Dispensary.—House Surgeon and Secretary. Salary, £120, with furnished rooms, &c. Applications to be forwarded not later than Dec. 5th.

West Bromwich District Hospital.—House Surgeon. Salary, £20, with board, &c. Applications to the Hon. Sec. on or before Dec. 9th.

Wolverhampton and Staffordshire General Hospital, Wolverhampton.—House Physician. Salary, £100, with board, &c. Also House Surgeon. Salary, £120, with board, &c. Applications to be addressed to the Chairman of the Medical Committee not later than Dec. 4th.

Appointments.

BICKLE, L. W., L.R.C.P., M.R.C.S., House Physician (non-resident) to St. Thomas's Hospital.

CLATWORTHY, H., M.R.C.S., Assistant Medical Officer to the Clapham and Wandsworth Infirmary.

COOPER, G. F., M.R.C.S., L.R.C.P., Assistant House Surgeon to St. Thomas's Hospital.

FELL, W., M.A., M.B. Oxon., L.R.C.P., M.R.C.S., Assistant Physician to St. Thomas's Hospital.

HAGBROWN, C. W., M.R.C.S., House Surgeon to St. Thomas's Hospital.

HOPWOOD, E. O., M.B. Oxon., Resident Medical Officer to the London Fever Hospital.

JONES, W., M.A., M.B. Oxon., M.R.C.S., House Physician to St. Thomas's Hospital.

MAHER, W. O., M.D., M.R.C.S., House Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

MARLOW, F. W., M.R.C.S., Ophthalmic Assistant to St. Thomas's Hospital.

OPENSHAW, T. H., M.R.C.S., House Physician to the London Hospital. **FRACOCK, A. L., M.R.C.S.,** Medical Officer to the Nos. 1 and 5 Districts and the Workhouse of the Lincoln Union.

RUSSELL, A. W., M.B. C.M. Aber., Senior House Surgeon to the General Infirmary, Macleodfield.

SUTHERLAND, R. T., M.B., C.M. Ed., House Surgeon to the Leith Hospital.

SUTTON, S. W., M.B. Lond., M.R.C.S., Resident Accoucheur to St. Thomas's Hospital.

WHITE, E. F., M.R.C.S., House Surgeon to St. Thomas's Hospital.

Births.

GRAY.—Nov. 18th, at Melbourne Terrace, Armagh, the wife of Dr. Robert Gray, of a son.

ILES.—Nov. 28th, at Watford, the wife of Wilson Iles, M.D., of a son.

MACSWINEY.—Nov. 18th, at Corradino, Malta, the wife of Surgeon-Major MacSwiney, M.D., A.M.D., of a daughter.

Marriages.

HARRISON—HEDLEY.—Nov. 24th, at St. George's, Hanover Square, London, Alfred Horatio Harrison, Associate King's College, to Mary, daughter of the late John Hogarth Hedley, M.D., M.R.C.S., late of Newcastle-upon-Tyne.

Deaths.

ALLOOCK.—Nov. 14th, at Smethwick, near Birmingham, Annarley Alloock, M.R.C.S., aged 69.

BUCKLE.—Nov. 19th, John Buckle, M.R.C.S.E., of Great Bardfield, Essex, aged 76.

BLOCKLEY.—Nov. 23rd, at Loane House, Upper Norwood, T. M. Blockley, M.D., C.B., Brigade Surgeon, A.M.D., aged 62.

DRAZELBY.—Nov. 22nd, at Skelga, co. Tyrone, Charles Drazelby, M.R.C.S., of Milford Haven, Pembrokehire, aged 64.

PERRIE.—Nov. 21st, at his residence, Aberdeen, William Pirrie, M.D., LL.D., F.R.S.E., Emeritus Professor of Surgery in the University of Aberdeen, aged 75.

FRITCHARD.—Nov. 24th, at 57 St. Paul's Road, Highbury, Andrew Fritchard, F.R.S.E., aged 78, after a long illness.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.
Surgeon to the London Hospital.

(Continued from page 457.)

In the extra-peritoneal ruptures the symptoms of peritonitis will be present, unless the peritoneum has been injured by the violence which occasioned the rupture of the bladder, or becomes involved secondarily, either by contact with urine effused under it, or in the course of the diffuse inflammation and sloughing of the sub-peritoneal connective tissue and fasciæ consequent upon extravasation of urine. The general symptoms, therefore, will be more subdued, but, sooner or later, there will be marked depression and evidence of septiciæmia. Chills, shivering, or actual rigors, clammy sweats, pale, earthy countenance, accelerated and feeble pulse, variable temperature, nausea and occasional vomiting, coldness of extremities, and muttering delirium will supervene, and the patient will succumb in a state of extreme prostration. In regard to the local symptoms, a less amount of urine may be expected to follow the introduction of the catheter than in the intra-peritoneal ruptures, as the point of the catheter will not readily enter the rent in the bladder. Nevertheless, manipulation with the finger in the rectum may occasionally succeed in causing the point of the catheter to pass through the rent into a pouch outside the bladder containing urine mixed with blood and the products of inflammation. The situation of the collection will vary according to the position of the opening in the bladder. When the rent is in front the urine either forms a circumscribed tumour outside and anteriorly to the bladder, occasioning marked dulness on percussion, or it becomes widely diffused, mounting up towards the umbilicus between the peritoneum and

the abdominal muscles, or passing into the iliac fossæ, or through the obturator foramina and the inguinal and femoral canals into the scrotum and thigh. When the opening is behind the prostate the fluid will ascend into one or other of the iliac fossæ. Wherever extravasation occurs, it sets up inflammation of the connective tissue and fasciæ, followed in due time by suppuration and sloughing. Occasionally the urine is collected in a kind of sacculus, the walls of which are composed of connective tissue matted by lymph, simulating the appearance of a lining membrane to the adventitious cavity.

A thorough acquaintance with the symptoms resulting from a ruptured bladder, and with the distinctive features of the intra-peritoneal and the extra-peritoneal rupture, ought to lead the surgeon to form a correct diagnosis in a typical case. But the frequency with which the practitioner encounters difficulty and doubt, overlooks the lesion, or mistakes for it a contusion of the bladder, or some other abdominal injury, proves that the diagnosis is not the easy matter depicted in some of the standard treatises on surgery. The diagnosis will be especially obscure if the surgeon cannot obtain a satisfactory history of the patient before coming under his care, and in cases in which the symptoms are masked or slight, and in which, possibly, the patient has passed urine voluntarily, or in which it flows from the urethra. The surgeon needs to be constantly on the alert, and to have his mind directed to the possibility of rupture, not only where there has been an abdominal injury, but in cases of retention from stricture, or from hypertrophy of the prostate gland, or from any other cause, and where the patient comes under his care stupefied with alcohol. In extra-peritoneal ruptures doubt will soon be removed by the occurrence of extravasation of urine; but in the intra-peritoneal ruptures I believe that the best local test is the possibility of passing the point of a long catheter through the rent into the peritoneal cavity, allowing free movement, and drawing off a large quantity of

fluid. When contrasted with a prior limitation of rotation and of depression, and the removal of blood or a very small quantity of bloody urine after the instrument has undoubtedly passed the prostate gland, the sudden slipping of the catheter up to the hilt in the urethra, with the effects stated, is extremely significant. Mr. Heath injected warm water through the catheter, and the stream was distinctly felt by the patient in the groins and abdomen. This means of diagnosis might be used where the surgeon could not make a diagnosis without it, but it tends to diffuse the urine already present in the peritoneal cavity, and it is probable that the warm water itself may exercise an injurious influence upon the peritoneum. On the other hand, if the bladder is sound, injection of fluid ought to furnish decisive evidence by causing the formation of a circumscribed tumour, which disappears on catheterism, with recovery of the fluid. It is scarcely possible to determine which is the more important mistake—to overlook a rupture of the bladder, and therefore fail to apply surgical measures promptly, or to mistake some other lesion for the injury, and subject the patient to an unnecessary and dangerous interference. There is another great disadvantage in mistaking some other form of abdominal injury for a ruptured bladder, or an extra-peritoneal for an intra-peritoneal rent. The case is published with a flourish, and the treatment pursued is quoted as well worthy of adoption, thus leading surgeons to apply to other cases means either prejudicial or inadequate. In recent years there has been a serious increase in the number of reported cases of recovery after an alleged rupture of the urinary bladder. Several are said to have been ruptures into the peritoneal cavity, and it would be quite impossible to decide from them what is the correct treatment of an intra-peritoneal rupture, inasmuch as expectancy and operative measures have been alike successful. As it is extremely important to arrive at a right conclusion in this matter, it will be useful to weigh critically the claims of the cases of asserted recovery; but before doing so one or two general observations are necessary.

1. In the first place, before accepting any case as a case of recovery after simple uncomplicated rupture of the bladder into the peritoneal cavity, it is desirable to have clear evidence that the bladder was full at the time of the accident. A distended bladder can scarcely escape from a severe blow or contusion of the abdomen; but a bladder empty, or nearly so, and under the protection of the pelvic bones, may elude the greatest violence.

2. Secondly, it must be borne in mind that the bladder may have been contused or dragged backwards; that blood may appear in the urine for some days after the injury; that the patient may be unable to micturate, though experiencing a strong desire to do so; and that there may be some difficulty in the passage of the catheter. A case of this kind I have had under my care at the London Hospital. After a severe contusion of the abdomen there were many of the signs of rupture of the bladder—blood drawn off with the catheter; bloody urine for several days; tenderness and swelling of the abdomen; and some of the symptoms of peritonitis. A very severe case occurred to Mr. Le Gros Clark. The patient was a man over whom an omnibus-wheel had passed. "The abdomen was severely contused, and he was in a state of collapse. Bloody urine was drawn off. On the following day he had severe pain in the belly and back. Fresh blood was mingled with the urine, and there was a noticeable variation in the temperature of the stream. Constant sickness was present. On the third day urine flowed through the catheter slowly, but free from blood, and was not accelerated by pressure on the abdomen. On the fifth day there was constant abdominal pain; pressure excited vomiting; and the abdomen was distended. He was delirious at night. On the seventh day it was evident that the distension was partly due to effusion; he said his belly

felt like a furnace. During the succeeding week the symptoms somewhat abated; the urine was abundant and clear. On the twentieth day the fluctuation in the distended abdomen was more distinct, and he suffered from frequent sharp pain; the urine was albuminous; the tension of the abdomen diminishing. On the thirty-first day there was a sensation communicated to the hand as of some solid body in the lower part of the abdomen gliding away under pressure; the tenderness had ceased. In six weeks he was well." With commendable hesitation Mr. Le Gros Clark observes:—"The nature of the lesion is conjectural, but for some days the symptoms were such as to induce me to suspect injury to the bladder, and the nature of the accident rendered it not improbable that such was the fact. Indeed, the favourable issue of the case alone points to an opposite conclusion. But is that conclusion of necessity justified by the result? I do not feel sure that it is." That the bladder was contused is very probable, unless the blood came from the kidney. The latter organ may have been bruised, for the wheel took a direction from the right groin upwards and outwards. That the bladder was ruptured I think is disproved by the absence of any evidence in the record of the case that the organ contained any considerable quantity of urine at the time of the accident, and of the typical primary symptoms, notably, the distressing desire and inability to micturate, and the peculiar results obtainable by manipulation after the passage of the catheter. Moreover, the quantity of urine passed does not appear to have been at any time defective. A more complete record of the case would have been desirable, but Mr. Le Gros Clark's philosophic caution is worthy of more general imitation.

3. In the third place, it may be affirmed that difficulty experienced in drawing off a patient's water, and the necessity for altering the direction of the catheter, or the position of the patient, &c., before succeeding, cannot be taken as conclusive evidence of a rupture of the bladder. It happens to every surgeon to meet with impediments to complete entrance into the bladder, and to removal of urine other than enlargement of the prostate gland. A blocked catheter, hitching in a fold of mucous membrane of the bladder, and, I believe, against a swollen right montanum, perhaps the entrance of the point into the sinus pocularis, a false passage—displacement of the bladder or effusion of blood may all come into play.

4. Fourthly, there is, as it seems to me, an erroneous opinion prevalent that the peritoneum often tolerates the presence of pent-up urine. At the discussion on Mr. Heath's case at the Medico-Chirurgical Society, my second case was mentioned as an illustration. As it happened, no case could more completely show the exact opposite of tolerance of the presence of urine by the peritoneum, both locally and constitutionally. With the exception of a brief interval of apparent improvement on the fourth day, the patient was in a most distressing condition throughout, with restlessness, wakefulness, vomiting, and pain. The peritonitis was intense, and lymph was found in abundance coating the intestine and bladder.

(To be continued.)

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

II.—*Definition—Causes—Geographical Distribution and Race—Age—Sex—Side—Influence of Scrofula and Tubercle—Presence of a Specific Poison in the Blood: Gonorrhoea, Small-Pox, Scarlet Fever, Puerperal Pyæmia, &c.—Traumatic Causes—Reflex Nervous Influence.*

Definition.—No careful observer would commit himself to a definition of morbus coxae which would not admit of expansion, and probably the safest plan would

be to avoid a definition altogether in this paper. Yet it seems only proper that the writer's idea of a disease should be stated, however roughly, at the outset of his description of it. For this purpose, therefore, I would venture to define hip-joint disease to be—*A disease met with in persons for the most part young in years, and of the habit of body known as strumous or tuberculous; in its origin either idiopathic or traumatic; in its nature inflammatory; in its course chronic; and in its termination destructive generally of the structures and functions of the joint.*

Causes.—Considerable diversity of opinion is, and has always been, held and expressed as to the causes of this affection, one set of observers contending that it is always of constitutional origin; another, that it is always due to violence. Among the first set may be mentioned Coulson, whose monograph upon the affection still remains a standard work. (a) As a type of observers of the second set, Lewis Sayre stands pre-eminently forward. (b) This authority goes so far as to say that scrofulous individuals are less likely than others to be the subjects of the affection, because, being invalids, they are less exposed to injury; and he considers it to affect principally those children who "run races, climb over fences, jump out of apple trees, kick their playmates downstairs, slide down balusters, and are generally reckless and careless."

The truth, however, probably lies between these extremes, for although a case may be exceptionally met with of purely constitutional, or purely traumatic, origin, yet it is to be observed that in nearly every case both a constitutional and a traumatic origin is to be found. Given an individual the subject of scrofula, or some other constitutional taint, any injury—however slight—to the hip-joint, if not followed by rest, will almost certainly produce the disease now under consideration.

It will be well, however, to consider somewhat briefly the various causes and circumstances which affect the production of morbus coxae, and the topics which will be dealt with are the following:—Geographical Distribution and Race; Sex; Age; Side; the influence of Scrofula and Tubercle; Exposure to Damp and Cold; Traumatic Causes; Reflex Nervous Influence.

Geographical Distribution and Race.—The disease appears to exist to a greater extent in England and Holland than in any other of the countries of the Old World. According to American writers, it appears also to be sufficiently common in the United States, so that the various branches of the great Anglo-Saxon race would appear to be predisposed to the affection. Coulson's explanation of this deserves reproduction for its ingenuity, if not for its accuracy; he says, "The Saxon population is characterised by the magnitude of the trunk and of the vital organs, while the limbs and locomotor system are small and feeble. . . . the locomotor system," therefore, this author urges, "becomes a sacrifice to the excess or derangement of the former." The real cause, however, of its frequency in certain nations is to be found probably in the greater activity of the people, induced by the colder climate, and injuries being, therefore, more common. It must also be borne in mind that the Anglo-Saxon race is peculiarly subject to scrofula. Among the Hebrews hip-joint disease appears to be peculiarly rare, and Mr. Barwell (c) accounts for this by the impossibility of the occurrence of phymosis. His reason for this view will be mentioned later on. Scrofula, again, we must remember, is rare among Hebrews.

Sex.—Females, on account of their more delicate constitution, have been held to be more prone to this disease than males. Bryant (d) avers that it is met with equally in the two sexes. Statistics, however—

examined for the purpose of this essay—make the disease more common among males. In 500 cases taken from various sources 298 were males and 202 females, a proportion of about three to two. This proportion exists also in each of the series from which the estimate is formed. Assuming the special liability of males to this affection, the explanation is to be found in their special liability to injury. It is a curious fact, however, that females at the age of puberty exhibit a proneness to the disease, due, probably, to the debility of constitution at this period.

Age.—Hip-joint disease may occur at any period of life. In the great majority of cases, however, it occurs during youth or adolescence. The youngest patient whose case I have been able to find recorded was under Mr. Coulson's care. The patient was a female infant, one month old. The oldest patient of whom I can find mention was a woman sixty years of age, who was affected apparently with a purely scrofulous form of the disease. She died at the age of seventy. The specimen is in the museum of the Royal College of Surgeons. (a)

The accompanying diagram (Fig. 2), which represents

The lightly-shaded portion represents the male cases; the darkly-shaded, the female cases.

the statistics of age drawn from four hundred cases, shows the following particulars:—1. That male cases are in excess of female cases at every period of life. 2. That the disparity between the sexes is small until the age of four is reached, at which age boys begin to have more freedom and exercise. 3. That after the age of four the male preponderance is very marked, and continues so throughout the rest of life. 4. That among females there seems to be a special liability to the disease between the ages of fourteen and sixteen.

The Side Affected.—In Mr. Bryant's experience sixty per cent. of the cases occur upon the left side. Mr. Hilton also records a preponderance of left-sided cases, and curiously, the museum of Guy's Hospital—of which Mr. Hilton was, and Mr. Bryant is, a surgeon—also contains an excess of specimens taken from the left side. This preponderance of left-sided cases is, however, contrary to the experience of most surgeons both here and abroad, and the statistics of the Hospital for Hip-joint Disease in London also show the right side to be more frequently affected. This proneness of the right side to be affected is probably referable to the right-handedness of man; man uses his right hand to ward off a blow, and advances his right leg to save a fall; and the fact that in females right side preponderance is less marked probably lends support to this view.

Bilateral cases are not common, and often get recorded where others are not, so that it is not easy to form a correct idea of their relative frequency. It may, however, be roughly estimated that they occur in the proportion of 2.0 per cent.

Influence of Scrofula and Tubercle.—That either of these conditions may be an element in the causation of morbus coxae has been held as certain by the chief authorities of past times, and is held by most surgeons of the present day. To these, however, must be mentioned three notable exceptions—viz., Holmes and Bryant in this country, and Sayre in New York. Holmes says, "the disease occurs very frequently in strumous children. . . . but it seems to have no

(a) Preparation No. 936.

necessary connection with struma." (a) Bryant observes, "To look upon hip-joint disease as a strumous affection is unquestionably wrong." Sayre denies *in toto* the influence of the disease, although in a table which he publishes of fifty-nine cases there is presumptive evidence of this affection in the patient or his family in twelve. For instance, in Case III. the mother "died of phthisis." Case XIX., "mother and child always delicate." "Patient died of marasmus and cholera infantum." Case XXII., "mother and child always delicate." Case XXVII., "patient's left lung extremely tuberculous." Case XXX., "father and child always delicate." Case XXXII., "died from fatty degeneration of the liver and kidneys." Case XXXVI., patient "delicate." Mother died of "consumption." Case XXXVII., patient "rather delicate." Mother died of "phthisis." Case XXXIX., died of "amyloid degeneration of the kidney." Case XLIV., patient had "waxy kidney," "fatty liver," and "general anasarca." Case XLV., father died of "phthisis." Case XLVIII., father died of "phthisis." Dr. Sayre's opinion is not shared by the majority of his brethren of the United States; and it certainly seems difficult to understand that this affection should be produced by a wrench, a strain, or standing too much upon one leg, in a previously healthy individual. I may state that in one hundred cases in which the family history was carefully examined, there is evidence of either scrofula or tubercle in forty-two.

The presence of a specific poison in the blood, as that of either rheumatism, pyæmia, syphilis, gonorrhœa, &c., may give rise to a disease of the hip-joint indistinguishable from that associated with struma. Coulson relates the case of a gentleman affected with gonorrhœa who became suddenly affected by hip-joint disease upon the sudden cessation of the urethral discharge. Ford (b) and Coulson also relate cases in which the disease seemed to be associated with small-pox. But in each of these cases the joint affection seems to have followed, and not to have been concurrent with, the zymotic disorder. Each case also gave evidence of scrofula. In one of Ford's cases the patient, when convalescent from small-pox, injured his hip by falling from a hay-rick. In the other cases there was no history of injury. Scarlet fever.—Croft, (c) Hilton, (d) Bryant, and Holmes each record a case in which the disease followed an attack of scarlet fever. In neither of these was there any known injury. Mr. Bryant's patient, who was strumous, died in the acute and early stage. Mr. Hilton's patient, the son of wealthy parents, made a good recovery with ankylosis. Mr. Croft's patient was submitted to the operation of excision, and recovered at the end of two years. Mr. Holmes' patient, who had scarlet fever in November, and morbus coxæ in December, also underwent the operation of excision. Measles seems also to have led to the disease in one case mentioned by Mr. Hilton. In this case there was no known accident, but the patient was scrofulous. Puerperal pyæmia not unfrequently leads to the occurrence of morbus coxæ. A very interesting specimen of ankylosis from this cause is to be seen in the museum of Guy's Hospital. (e) Coulson relates a curious case in which the patient was pregnant six times subsequently to the onset of hip-disease; during each pregnancy the joint symptoms became subdued, and became worse again upon the termination of the pregnancy. A patient admitted into the London Hospital had ankylosis of both joints following a confinement. Mr. Maunder performed osteotomy on each side with a good result. (f)

Syphilis, pneumonia, empyema, typhoid fever, and gout, have all been credited with being the starting

point of morbus coxæ, and Coulson asserts that it may result in part from suppressed menstrual or lochial discharge or lacteal secretion.

In all cases, however, in which the joint disease has followed these affections it is a question whether it is necessary to look for more than the debilitated state of health produced by them as a cause.

Traumatic Causes.—The hip-joint is so deeply placed and so well covered by soft parts that it is less liable to injury than many other joints, while its position does not save it from those influences of constitutional nature which act through the circulation. The disease, however, is frequently found to be set up by violence, and this may be either *active* or *passive*. Under the term *active violence* is to be included all injuries which are sudden and severe, as falls, blows, strains, and wrenches. In about three-fifths of the cases evidence of injury of this kind will be found. *Passive violence* may be defined as the exercise of the natural functions of the joint continued for too long a time without compensatory rest, such as over-walking, or standing too long. It is probable, however, that acts of passive violence only occasion the disease in persons of depraved constitution.

Reflex Nervous Influence.—The theory that hip-joint disease may be due to reflex nervous influence is promulgated by a surgeon of great experience and critical observation, Mr. Barwell. Mr. Barwell noticed that a boy with hip-disease had also a very long prepuce, and the co-existence of these two states appeared to him so constant that he determined to take notes of one hundred cases, the result being the discovery of phymosis in eighty-three. In support of his view Mr. Barwell refers to the partial exemption of Hebrew children from the disease. With regard to girls affected with hip-disease, Mr. Barwell believes that in many cases there exists also in them vaginitis, vulvitis, or some affection of the nymphæ.

Assuming the accuracy of Mr. Barwell's observations, it would seem necessary before accepting his theory of connection between the genital organs and hip-disease, to solve the following problems:—

1. If due to reflex nervous influence, why is the disease not more frequently bilateral?
2. How is it that the hip-joint alone should be affected when the nerves which supply it supply also other joints?
3. What is the percentage of boys who have phymosis and have not morbus coxæ?
4. As to females, is there not a large number of weakly girls who suffer from vulvitis, vaginitis, &c., who have no hip-disease?

TREATMENT OF NEURALGIA. (a)

By CHARLES R. FRANCIS, M.B. Lond., &c., &c.,
Formerly Professor of Medicine in the Medical College, Calcutta

(Continued from page 450.)

ONE of the worst cases of neuralgia, that I have seen, occurred in the person of Mr. F., a gentleman from Melbourne, whom I met, in 1879, at an hydropathic establishment at Malvern. A most intelligent and agreeable member of society, he possessed the nervous constitution in an eminent degree, and was always "up or down." His history was this:—Twenty-five years previously he had gone to Australia to become a sheep-farmer; and for ten years lived, like his companions in the bush, chiefly on *dampers*. Being young and strong, he digested them without difficulty. He then came home, and, after a short leave, returned with a wife. Again his fare, extending over another ten years, consisted mainly of *dampers*. But now the burden was too much for the stomach, which showed its intolerance by flatulence, and pain after meals.

(a) Read before the Harvelian Society of London, Nov. 16th, 1882.

(e) Preparation No. 1818 4s.

(f) Maunder, "Lond. Hosp. Reports," 1877.

Gradually the latter became more and more severe, until at length the agony was almost insupportable; and death would have been welcome. Twice in the twenty-four hours, at intervals of a week or so, and usually about 11 a.m. and at midnight, pain would make its appearance, when the stomach would seem to be twisted into a knot. There was a mixture of flatulence and gastrodynia. Slight relief would follow the administration of a powerful carminative. There was one symptom in the case that is noteworthy. Mr. F. suffered occasionally from nausea. At those times he was always quite free from pain. As in the preceding cases, the attacks would recur for three or four days in succession, and then become more moderate, occasionally ceasing altogether for a week or more. When suffering from an attack, Mr. F. would descend, if it were in the night, into the large dining room of the house, and roam up and down for several hours holding his hands against his stomach; or kneel by the sofa and press his stomach up against it. Pressure appeared to give slight relief. As Mr. F. was deriving no benefit from the hydropathic treatment, it was arranged that my suggestions should be acted upon. In the first place, in view to the food being suitable and well cooked, he was provided with a separate and experienced *cuisinier*. There was no malaria in the case, but, clearly, periodicity. Quinine was inadmissible, as, when formerly taken, the tinnitus and other physiological results had been so pronounced; indeed, Mr. F. objected to take it. Sulphate of cinchonine, however, with Fowler's solution and an anodyne, answered the same purpose. The periodicity was soon broken through, and Mr. F.'s joy was great; but he would not take any intermediate medicine. He believed in the antiperiodic but not in the supplementary treatment, of which, he said, he had previously had enough. Notwithstanding, by careful attention to diet and the exhibition of liq. pot. arsen., instead of cinchonine, which Mr. F. got to dislike almost as much as quinine, his general health gradually improved, whilst the attacks of pain recurred at longer intervals, and were more bearable. Mr. F. left for Melbourne on the approach of our winter, which he was afraid to face, in excellent spirits, and in full expectation on arriving in the warmer climate of that quarter of the Antipodes, of losing his neuralgia altogether.

It is singular what erroneous ideas are entertained by even intelligent persons in reference to the treatment of neuralgia. This gentleman believed, until I pointed out the fallacy of the notion, that excessive exercise was good for his disorder; though he afterwards remembered that his most violent attacks had occurred in the nights succeeding the days on which he had taken his longest walks, and when he had come in quite tired out. Further, he could not understand why, as fruit was intended for human consumption, he should not eat pears and plums in their season, provided they were ripe. After a few unpleasant experiences, he eventually realised that perhaps his stomach might be, after nearly a quarter of a century of irritation, more tender than that of others whose food through the same period of time had been more digestible than "dampers!"

It may seem a work of supererogation to insist upon the necessity for a neuralgic patient to live generously, the food containing plenty of fat or other heat-producing material; but I so frequently meet with persons who have not only not had the necessity pointed out to them, but who have actually been treated on the opposite plan, that I venture to speak of it. Quite lately, in Essex, I saw a hearty, elderly clergyman, who at intervals of varying lengths had an attack of neuralgia in his right arm and the left thumb. Until recently he had been kept low at these times. Being of a full habit, a hearty eater, and rather short-necked, his medical attendant had probably thought that abstinence might be beneficial. But, however useful such

treatment might be in averting an attack of cerebral hæmorrhage, it would make the nerve affected more susceptible of pain than ever. And it is, moreover, in direct opposition to the now generally-credited dictum of Romberg, that neuralgia is the prayer of the suffering nerve for healthy blood—and probably plenty of it! On the last occasion, a clerical neighbour who was fond of good cheer, seeing how low his friend had become without any relief whatever to the pain, carried him off to his own home, and there fed him up. The change of air and scene, including a holiday from continual mental strain, added to the better living, led to the patient's rapid recovery. The public generally attach but little importance to the necessity for plenty of good food. They far more readily have recourse to stimulants. With some, sherry is a *certain* remedy; with others, champagne; with the majority, port, or porter. Not only are these alcoholic drinks valued as pain-killers, but for their (supposed) *nourishing* properties. Alcohol, in my experience, does harm—in many instances very great harm—in neuralgia. The depression that follows the temporary elevation which accompanies the relief from pain renders the nerve more susceptible of an attack than before, to say nothing of the craving for drink that *must* be, and too often is engendered. Alcohol is perhaps the pleasantest of pain-killers, but it leaves behind a terrible sting. It is very much in consequence of a portion of this sting—viz., the narcotising effects of alcohol—that brandy, which when I first went to India some thirty years ago was with many medical officers a sheet-anchor in the treatment of cholera, has now been abandoned, ether and other diffusible stimulants being substituted for it.

The appetite in neuralgia is apt to be capricious, owing to frequent recourse to alcoholic pain-killers, as it is also by drinking too much tea, which is a common cause amongst the poor in this country not only of flatulence (called by them wind spasm), but of gastrodynia. What opium does in arresting appetite and the waste of tissue in the East is effected by tea amongst our working classes—the abuse of tea is, unfortunately, not limited to them—in the West; and the excess to which it is taken often does infinite harm to the nervous system. A lady in England once wrote to her husband in India: "If you wish ever to see me again, come home at once; I am very ill." She asked her medical attendant to write, too, which he did; and gave her a sealed note to be enclosed in her own letter. His words were: "Stay where you are; if your wife would only take less tea she would be quite well." The quantity of tea that is drunk—hot tea, too—in some families is surprising. Beginning in the early morning, even within an hour or so of breakfast, they drink it at varying intervals throughout the twenty-four hours, both *at* and *between* meals; and then wonder that their appetites are so bad. Such persons are peculiarly liable to neuralgia.

Neuralgic patients are often broken down in health; hence the paramount importance of attending, primarily, to the digestive system, and of building up the framework by its means. As in many other disorders, so *a fortiori* in neuralgia, we shall acquire considerable vantage ground by improving the appetite, and encouraging the patient to satisfy it with good flesh-forming and heat-producing food, and abstaining as much as possible from fluids of any description. A few minims of dilute nitro-hydrochloric acid, either alone, in water, or some bitter infusion—*cheretta* for preference—taken immediately before a meal, will often act like a charm in inducing an appetite and promoting digestion. Doubtless there are other equally efficacious promoters of appetite and digestion; but I am quite satisfied with the nitro-hydrochloric acid. Cod-liver oil does good in almost every case; and, provided the patient will live rationally and abide by rules applicable to his or her own particular case, is frequently the only medicine that need be taken.

In this connection I will give the outline of a most unpromising case of migraine that came under my observation about four years ago.

A well-known Manchester merchant, whose business was very extensive, requiring continued and close application, consulted me on account of this disease, which made his life wretched for some thirty-six hours once in ten days or a fortnight. Everything, he said, had been tried, but he was as bad as ever. I felt satisfied that unless he could take more rest the disease would never leave him, do what we might. Yachting in the Mediterranean had been recommended; and in this I cordially acquiesced. A few days ago I received a most satisfactory letter from the gentleman, in which he says: "I have been gradually relieved of my former suffering, and have been quite free for the past twelve months; but I attribute much of this to taking longer rest, as each of the last four years I have spent from two to four months yachting. My medical man also put me under a tonic plan of treatment by a preparation of steel. . . . The steel improved the appetite; and a liberal diet, with fresh air, have added flesh to my body, so that with ordinary care I am well able to stand a considerable amount of work and fatigue without suffering any consequences." This result is especially gratifying and encouraging, as the patient is over 50; he had suffered for many years; and the disorder is in his family. The neuralgia-suffering public are (naturally enough) eager to take a dose that will kill the pain; but they are not so ready to lead the rational life, or go through a course of treatment, which might prevent its advent. Yachting can, of course, be indulged in only by the few; and the taking rest is, in too many cases, synonymous with starvation. Still, it is satisfactory to know that, where our advice can be followed, the results will usually justify us in having given it.

I have so far spoken only of neuralgia, pure and simple. But there are some disorders in which it comes to be the most prominent feature—constitutional disorders upon which the neuralgia has, as it were, engrafted itself; and the cure of which in many cases involves the cure of the disorder, though in others remedies suitable to both are required—*e.g.*, gouty and rheumatic neuralgia, syphilitic neuralgia, &c.

Anstie states, and so far as my own experience has gone I can endorse his statement, that syphilis is not a powerful factor in causing neuralgia. It induces motor-paralysis readily enough, but it does not so readily affect the sensory system.

Periodicity, if carefully sought for, will usually be discovered. Major W. consulted me on account of gout in his right great toe. There was considerable pain and some swelling, the surface being of a dull red. Major W. begged for leeches. He had often, he said, had such an attack before, and leeches had always relieved him. The pain was always worse about bed-time. Ten grains of quinine with a quarter of a grain of morphia, given on two successive evenings about 9 o'clock, removed all pain without the aid of any local application, to the great joy and surprise of the major. The swelling quickly subsided.

Corporal L. was admitted into the regimental hospital of the 4th Europeans, of which I was then in medical charge, at Lucknow. He complained of rheumatism in the right knee-joint, extending down the leg to the ankle, which was also involved. He had contracted the disorder in Burmah two years previously, and had several times been in hospital on account of it. In this case, too, the pain was worse as evening advanced. He was treated much in the same way as Major W., and left the hospital well and fit for duty in a few days, saying when he went that he had expected to remain as many weeks.

Colonel C., then resident at Nynee Tal, (a) somewhat

(a) Nynee Tal is a somewhat damp sanatorium.

of a *bon vivant* (and whose father died of gout in the stomach), had a severe attack of neuralgia in the right eye. For three successive nights he endured the agony, which was indescribable, without seeking for medical aid; but on the morning after the third night he sent for me. I treated him on the old orthodox plan for gout (it was thirty years ago) without the slightest benefit accruing. The pain recurred under this treatment for two consecutive nights as violently as ever. Towards the night of the third day I gave the patient twenty grains of quinine with a quarter of a grain of morphia. The medicine made him very sick, and the tinnitus was great; but there was no pain. Henceforth the remedy was in his own hands. Attention to diet, a gentle aperient when necessary, followed by a few grains of quinine (without any anodyne) when he had reason to expect an attack, always staved it off.

(To be continued.)

Clinical Records.

MATER MISERICORDIÆ HOSPITAL.

Case of Disarticulation of the Hip for Sarcoma of the Thigh.

Under the care of P. J. HAYES, F.R.C.S.E.,
Senior Surgeon to the Hospital.

I HAVE selected for publication in the *Medical Press* the case of a patient who recently underwent disarticulation at the hip-joint for removal of a sarcoma affecting the thigh. This patient was treated at different periods in the Mater Misericordiæ Hospital, and I am indebted to my friend Mr. Coppinger for memoranda respecting the case, which he kindly copied from his operation register, and which I have incorporated with other particulars in the following report:—

Maria S., a healthy-looking, dark-complexioned girl, at the age of eighteen began to experience pain, attended with a very slight degree of swelling, about the outer side of the right knee, and it would appear that this pain was not the result of any injury to the joint. The girl early sought professional advice, and the surgeons whom she consulted came to the conclusion that the affection from which she suffered was of a neuralgic character. The girl, however, was not at all of a nervous temperament, and furthermore, pain was experienced only when the joint was subjected to movement, or when pressure was applied over its external aspect. For two years the patient tolerated the pain which walking caused her, but then she became so lame as to be no longer able to work, and consequently she applied for admission at the Mater Misericordiæ Hospital. She was placed under the care of the late Mr. Tyrrell, and, as all ordinary measures failed to afford her relief, he determined to carefully cut down upon the outer side of the knee and explore the painful region. This operation was performed March 3rd, 1875, and Mr. Tyrrell exposed a small tumour, which seemed to be adherent to the imperfect capsule of the joint. I believe Mr. Tyrrell looked upon the growth as being of neuromatous nature; he did not remove it, and the wound was allowed to heal by granulation. Then the girl returned to her home in the country.

After the lapse of two years Maria S. was again admitted to hospital and placed under my care. At this time her sufferings had increased very much, and the circumference of the affected knee was notably greater than that of the healthy joint. Indications now pointed to the probability of there being loose bodies within the articulation; and having consulted with my colleague, Mr. Coppinger, I decided to open the synovial cavity, using full antiseptic precautions. The joint was opened April 18th, 1877, and three fragments of what seemed to be calcified cartilage were at once detected and removed; at the same time the synovial membrane at the outer part of the knee felt under the finger as though it had undergone well-marked pulpy thickening. Painful startings of the limb were experienced during the first forty-eight hours following the operation, then they subsided, and on the third day complete union of the wound was found to have taken place.

A note of the case written in the month of June, 1877, mentions that the patient continued to suffer from pain, and disability of the joint, but that local temperature was not

abnormal, and there was not wasting of the limb. In the following August I resolved to excise the knee, as I had excellent reason to believe that pulpy change of the synovial membrane existed; also it was clear that rest and other appropriate treatment had failed to produce any favourable impression upon, or even to arrest the progress of the disease.

When the day for operation arrived I found I was singular in holding the view that my patient's case was sufficiently grave to demand excision. I consequently yielded to the judgment of my colleagues. The skin over the outer side of the knee was cauterized with the hot iron. I put up the limb in a gypsum case, and shortly afterwards the girl was recommended to leave hospital.

Early in December, 1879, Maria S. entered hospital for the third time. The condition of her knee had steadily progressed from bad to worse, and she had resolved to undergo whatever operation might be deemed proper to rid her of the diseased joint. At this period the knee presented a very peculiar appearance. Though somewhat globular in form, it was unequally enlarged, and on the outer side two nipple-like projections were to be noticed. The projections were about the size of walnuts; they were so soft as almost to seem fluctuating, and the skin covering them was extremely thin, smooth, and red almost to lividity.

The girl was made aware that in the opinion of the surgeons it would be necessary to amputate through the thigh, but at her particular request I promised to make such an incision as would expose the growth and afford an opportunity for excising the joint in the event of there being a possibility of saving the limb.

On December 18th the growth was laid bare by a curved incision carried across the knee. It proved to be a sarcoma of soft, marrow-like consistence, which covered, and to a certain extent penetrated, the outer condyle of the femur, over which it ascended for a distance of two and a-half inches. Amputation was performed well above the tumour, the girl recovered rapidly, and a few weeks later she returned to the country in excellent health. Mr. Copinger kindly prepared sections of the tumour. It proved to be spindle-celled sarcoma, which seemed to have become incorporated with the synovial membrane of the knee.

Last December (1881) Maria S. once more became my patient. She stated that for six or eight months after amputation her health remained in very good condition. She then noticed the development of a swelling more or less circumscribed which formed in the lower and anterior part of the stump. This growth soon became tender and painful. Ultimately the skin covering it became the seat of ulceration, permitting the protrusion of a fungoid mass, which bled freely under the slightest provocation. Of late hæmorrhages had become so frequent as well as profuse that her life was at times placed in extreme danger. I found the girl in a very depressed state of health; she presented quite a blanched appearance; and it was evident she must have recently lost a large amount of blood.

Examination of the diseased part revealed the existence of a large sarcomatous growth, which gave a bulbous form to the lower extremity of the stump. A circular, well-defined aperture in the thin and livid skin gave exit to a soft, friable fungus, which was in part covered with adherent blood-clots. The cicatrix of the amputation wound was altogether behind, and distinct from the tumour.

It was not easy to determine the origin of the sarcoma, but as it was evidently connected with the lower end of the divided femur, I judged it as being likely to have such relations with the bone as to render disarticulation at the hip-joint the only suitable procedure for effecting its complete removal. The patient accepted my proposal, and on Jan. 12th in the present year I performed disarticulation according to the method practised by Mr. Furneaux Jordan, of Birmingham. Very little blood escaped through the wound during the operation, but movement of the stump caused the sarcoma to bleed so freely as to necessitate the application of a tightly drawn roller above the fungus.

The girl remained in a very prostrate condition for some hours, but the administration of two hypodermic injections of ether caused her to rally, and she made an uninterrupted recovery. I may add that, under antiseptic dressings the wound united throughout by adhesion, save where two drainage tubes were inserted to secure exit for serous discharge.

Maria S. is now at home; she seems to be in particularly good health; but it remains to be seen whether secondary

development or local recurrence of sarcoma may not again bring her under observation at hospital. Mr. Copinger mounted sections of the sarcoma, which exhibit the spindle-celled structure of the growth.

The history of the foregoing case is peculiar and interesting. The sequence of events, so far as morbid action is concerned, would lead to the conclusion that at first neoplasms formed in the substance of, and probably also external to, the synovial membrane. Then three masses of dense consistence became pedunculated within the articular cavity, whilst at the same time prolonged irritation caused inflammatory (?) thickening of the synovial membrane. Later, it would seem that the comparatively simple tissue-change produced by inflammatory action gave place to cell-growth of sarcomatous character, and in time the existence of this process at one part so affected or impressed neighbouring masses of protoplasm as to determine in them a repetition of the process which became notable after removal of the primary growth.

The recurrent tumour seems to have sprung from the periosteum and other fibrous investments of the femur; hence it is probable that a very high amputation through the femur would have afforded a prospect of security against repetition of the disease equal to that obtained by disarticulation at the hip.

It may not be superfluous to append a few remarks respecting the conditions which seem to determine the appearance of loose bodies in joints. Fischer, of Breslau, has analysed the views of various writers respecting the origin of such bodies, and the following summary will serve to represent his conclusions.

Loose bodies suddenly appearing in previously healthy joints will probably depend upon the detachment, by injury, of a fragment of articular cartilage, with perhaps a layer of the underlying bone. Any such loose body will be dense in substance, and likely to persist, causing distress and recurrent attacks of synovitis (Paget, Teale).

Hunter and Virchow believed that blood effused within a synovial cavity might become hardened, or even calcified, but according to Fischer the presence of any such effusion will be of temporary duration only, as complete absorption will take place after the lapse of a few months.

Intra-articular masses of fibrous consistence were described by Ambrose Paré, who thought that partial coagulation of synovia might occur; but plastic exudations from the synovial surface constitute the masses to be observed in the synovial fluid, constituting the hydrops fibrinosus articuli of Volkman.

Growths of inflammatory origin may, as Rokitsky pointed out, become developed in portions of the synovial membrane, more especially in the fringed processes, and either remain as pedunculated formations, or, by atrophy and rupture of the pedicle, be set free within the joint.

Laennec and Billroth describe the development of more or less dense masses in the deep strata of the capsular investment of a joint, their inward bulging, or inversion of the synovial membrane, allowing the growths to project into the joint, until ultimately they become pedunculated, and possibly even detached as loose intra-articular bodies. Such bodies may be fibrous, cartilaginous, calcified, or bony.

With regard to treatment, sometimes when the body can be slipped into a superficial fold of the synovial sac it may, as Gooch recommended, be kept out of harm's way by carrying a couple of tightly-applied strips of adhesive plaster over the skin at either side of the mass, which can be caused to bulge in the elliptical space between the straps. This, with rest, as enjoined by Hilton, and the application of a small blister to the exposed skin covering the mass, will in some instances secure fixation of the body in such a position as shall preserve the patient from pain or injury.

Abernethy used to extract loose bodies through a valvular incision. Iarry preferred making a subcutaneous wound of the synovial membrane, through which the loose body could be slipped into the tissues outside the joint. Syme favoured the plan of making a subcutaneous wound through the synovial membrane and into the body. Then he applied a blister over the region of this subcutaneous wound, in order to determine adhesion of the mass to the synovial wound.

In the present day Listerism enables us to open joints and remove from them morbid formations without exposing our patients to the dangers which heretofore rendered ingenious surgical devices necessary. A word respecting Jordan's mode of performing disarticulation at the hip. The operation practically consists in making a vertical incision from a point a

little above the hip-joint to the outer side of the femur and carrying the wound for a considerable distance down the thigh. The surgeon can through this longitudinal wound separate soft tissues from the anterior, inner, and posterior aspects of the femur, up to the hip-joint, without incurring the risk of exciting hæmorrhage. The ligaments of the joint next require to be divided, when the upper part of the femur can be caused to emerge through the incision. The soft structures of the thigh are then to be compressed and severed either transversely or obliquely, the vessels can be at once secured, and closure of the wound effected.

The advantages of this procedure are obvious: the patient is saved from much loss of blood, and there is no need for using Davy's lever, an objectionable instrument, which has inflicted fatal injury even when employed by the skilful hand of the inventor.

The amount of shock is considerably less than that which must attend disarticulation otherwise performed, and the wound is so placed as to favour free drainage as well as early union. The operation, however, requires more time for its performance, and is less showy than disarticulation effected by Liston's transfixion method.

The foregoing report was written several months since, but its publication was postponed in order that the lapse of sufficient time should be allowed to enable me fairly to judge whether the operation was likely to prove successful in ridding the patient of sarcomatous disease.

Some difficulty was experienced in discovering the patient's address, and to the courtesy of Mr. Cornwall, Secretary to the General Post Office, I am indebted for information that the woman is now in good health. The subjoined letter was lately received by Dr. Thunder, House Surgeon to the Mater Misericordie Hospital:

Ballinamore, Nov. 22, 1882.

DEAR SIR,—I hope you will pardon delay in answering your very kind letter sooner. I was away in a friend's place when your letter came. I only received it on my return, two days ago. I wrote Sister M. Borgia how I was getting on. I am happy to tell you I never was in better health. No tenderness or soreness about the stump; has its natural colour same as rest of my body; never felt a pain since I left the hospital. I would venture to America if I thought I would be accepted on board vessel.

I hope Mr. Hayes will not think it ungrateful of me not writing himself, after having saved my life. Surely were it not for his extraordinary anxiety and trouble with me, I would not be on the lands of the living to-day. If there was a photographer here, I would send him my carte, as he could not imagine how I am improved in strength and appearance. Only my circumstances would not afford it, I would not think it too much to go see him, but I regret not having means to do so.

I remain,

Yours respectfully,
MARIA S.

Special.

LONG MARCHES.

At the present time, when on all sides, and very justly, praise and admiration are expressed for the troops who, by a rapid and forced march across the desert from Tel-el-Kebir to Cairo, contributed to the success of the Egyptian Expedition, it is well that the circumstance should be remembered that during the Indian Mutiny some marches of a much more notable character even than that one were performed by British Infantry, and at a season of the year when the heat of the day was absolutely intense; one such march deserves special record. After Azimghur had been "relieved" in April 1858, a field force was despatched in pursuit of the defeated rebels, who fled towards the Ganges. That force consisted of the 10th and 84th regiments of British Infantry and Royal Artillery; the troops who formed it had previously undergone a succession of long and fatiguing marches from Lucknow, including two somewhat severe engagements against the mutineers. They resumed their march with alacrity from

Azimghur, however, and in three days and a-half had completed a distance of one hundred and four miles. What constituted the peculiarity of this march was the season of the year in which it was performed and the very great heat then prevailing. There are other marches which deserve to be noticed. In 1706 the 34th regiment, in order to come to the "relief" of Barcelona, marched, or, more properly, were carried on mules, over a distance of forty leagues in two days. In 1745, after the battle of Fontenoy, a body of troops, composed partly of 42nd Highlanders and Dutch, was employed in covering the march of a garrison of Austrians to Mons. In the last day's march of more than thirty miles along a sandy road, and at the end of June, the Dutch troops became overpowered with fatigue, but not a man of the Highlanders had to be left behind *en route*. In 1777 the 10th Foot marched from Kilkenny to Dublin, a distance of seventy miles, in twenty-four hours. On the 18th July, 1801, this same 10th Foot, together with the 8th Hussars and 61st Regiment, started from Kossier. They suffered much from excessive heat, thirst, and fatigue during the ten days occupied by them in crossing the Desert; yet, when at the end of that time they reached Kenneh on the Nile, their whole loss was only one man by fatigue. This circumstance is of importance, as furnishing a standard of comparison in regard to recent events. On 16th of June, 1815, the 1st Royal Dragoons marched fifty miles to Quatre Bras, reaching that place at dusk and after the battle had ceased. In 1826, during the first Burmese War, the 1st battalion of the Madras (native) Sappers and Miners marched in the hottest period of the year at the rate of twenty-five miles per day for fifteen days without a halt.

COLONIAL MEDICINE.

At the International Colonial Exhibition which is to be held at Amsterdam from May to October, 1883, it has been decided, on the invitation of the Dutch Association for the Advancement of Medical Science, that a section representing Colonial Medicine shall be opened simultaneously with the Colonial Exhibition; the object being defined as of a strictly scientific character—viz., to promote our knowledge of the sanitary and medical conditions in the Colonies. This section will be divided into three classes.

The first class will embrace everything relative to the public health in the colonies and transoceanic possessions. It is generally admitted that the welfare of colonies is closely connected with the health as well of the European population as of the natives, but the opinions as to the best way to attend to the health of the population under the various conditions of climate, tropical diseases, customs and habits, are still unsettled, principally from want of a sufficient knowledge of facts. This section will serve, it is hoped, as a guide to the Governments in introducing sanitary improvements or in remedying the existing defects in the various colonies.

The second class is of equally practical importance. It will be devoted to all data connected with the organisation of the medical service in the colonies, in regard to which the several colonial Governments follow different systems, and it is only by a careful study of them that a correct judgment can be formed as to the best system to be adopted.

The third class will have for its scope the attendance to the sick and wounded, and their transport, and also their treatment by the natives. In all civilized countries this attendance is a subject of public care and interest; but in the colonies there are special circumstances to be taken into consideration, such as are connected with the nature of the tropical diseases, the habits of the population, and the difficulties in obtaining the

necessary means for the proper treatment, transport, and attendance of the patients. It is not too much to say that a collection, as complete as possible, of everything bearing upon this subject would be instructive in the highest degree. A comparison of what is achieved in the colonies under extraordinary circumstances with what is done in the mother countries will undoubtedly lead to results beneficial both to science and humanity. This class will also comprise everything connected with the mode of treatment of the sick and wounded by the natives themselves. Both the natives and the colonists are in this respect actuated by the same motives of humanity, but the means they use are different. Although it may be contended that the means employed by the natives are for the greater part of a primitive character, yet it should not be forgotten that many medicaments and modes of curing applied in medical science have been discovered by these very natives, and their salutary effect acknowledged by popular experience long before they were used in scientific medicine. All objects relative to these modes of treatment by natives, even those of which the origin is not or little known, will be very welcome to the Committee. The Committee is well aware that these three classes do not comprise all that a programme of a medical exhibition relative to colonies should contain in order to be in any way complete; nor does the Committee forget that in the subdivisions of the three classes a great many things are omitted that are important in more than one respect. But in view of the limited time allowed before the opening of the Exhibition, the Committee has been compelled to confine itself to the three classes mentioned. As, however, the subject is one of a strictly scientific character, it is, of course, not intended to exclude whatever may not have been specially mentioned. On the contrary, every contribution which may serve to promote the object of the Medical Exhibition will be thankfully received. The space allotted to the Medical Exhibition being a limited one, the models, plans, drawings, &c., of the objects will be preferred to the objects themselves, if the latter should be too voluminous. This, however, does not apply to those subdivisions of classes for which objects *in natura* have been solicited. The space required for the Medical Section will be allotted free of any cost. Objects of a commercial or not strictly scientific character will not be admitted. Exceptions may be made in such cases where duplicates are already exhibited in one of the other sections.

The objects intended for the Medical Section will be received up to the 1st April next, and the packages should be marked, "Exhibition of Amsterdam.—Section: Colonial Medicine."

It is intended to hold an International Congress for Colonial Medicine during the Exhibition in September, 1883, the programme of which will be published in due course.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

TYPHOID FEVER.—The epidemic of typhoid fever, which I may say in passing, is decreasing sensibly, recently occupied a whole *séance* of the Academy of Medicine. M. Gueneau de Mussy opened the discussion on the cause of the affection. He reminded his colleagues that in his work upon the causes of typhoid fever, which he presented to the Academy four or five years ago, he insisted that the malady was contagious and specific, and affirmed that its origin, in almost every case, should be placed in the alvine evacuations of the patient. This idea has been since generally accepted, and in consequence, the utmost attention

should be bestowed on the manner in which the dwellings are drained. He considered that the whole system of the sewers in Paris was entirely inadequate to the increase of the population, and flushing was not sufficiently performed. The dwellings of the poor were in a wretched state, the air respired was largely charged with emanations from the water-closets. Prophylactic measures should be urged on the Corporation before any chance of stamping out the epidemic of typhoid fever or of diphtheria, which latter disease recognised, in many cases, the same cause. He thought that compulsory notification of all infectious diseases should be brought into practice, in order that the rich should be forced to take proper sanitary precautions at their own expense, and that the town, in the case of the poor, should furnish the means necessary. M. Rochard quite agreed with his learned colleague, and was also of opinion that the disease in question was the outcome of over-crowding and filth. It attacked in preference, young men badly nourished, badly lodged, and over-worked. As to over-crowding being a powerful cause of the affection, the evidence was incontestible. In barracks it was not rare, and in Paris, where in 1874 the number of deaths from diphtheria and typhoid fever were comparatively few, in 1881 they had more than doubled; the same might be said of small-pox, measles, and scarlatina. The present epidemic has carried off already 2,300 persons, which was a number really considerable, but within the last few days the fever has assumed a more benign type, the death-rate being one in fifteen. He considered this disease might be justly attributed to the change in the atmosphere, the heavy rains having washed the houses from top to bottom and flushed the sewers. As to the prophylactic measures, he considered that the value of disinfectants was exaggerated, and especially the necessity of isolation in typhoid fever, which was not nearly so transmissible as small-pox or scarlatina. Up to the present, only twenty-five cases originated in the hospitals, and not a student, surgeon, or nurse has been affected. He advocated the drawing up of a report, to be presented to the Board of Health advising strict sanitary measures to be taken with the least possible delay. M. Hérard being invited by M. Guérin to give his treatment of the fever in his hospital practice, replied that he found the sulphate of quinine in large doses (40 to 50 grs.) to be of the most use. The patients bore it very easily, taking it in wafers. He tried other remedies such as salicylic acid, warm baths, &c., but not with such good results. M. Bourdon doubted that the patients were able to absorb the quinine, unless they were given subsequently acid drinks. Another member thought the classical remedy of purgatives, with proper sanitary precautions, the best treatment. The treatment of M. Hérard was undoubtedly very expensive, although he could not see what inconvenience such a large dose of quinine could cause.

CHLORATE OF POTASH IN CANCEROID AFFECTIONS.—This salt as an application to canceroid affections, such as epithelioma, lupus, &c., has not met with the encouragement it deserves. A medical man has just treated, in a very effectual and rapid manner, a case of the latter by the application of the salt in powder. From the first, the ulcerated surface began to improve, and in a month cicatrisation was complete. No other treatment was used, although previously many other things were tried. The disease was of five years standing.

M. BURCQ ("Comptes Rendus") shows that copper has a powerful disinfective and antiseptic action.

Transactions of Societies.

OBSTETRICAL SOCIETY OF EDINBURGH.

THE Society met in their Hall, St. Andrew's Square, on Wednesday last, 29th November, Dr. Carmichael, Vice-President, in the chair.

Dr. HART exhibited a pregnant uterus about the third month.

APPOINTMENT OF A PATHOLOGICAL COMMITTEE.

Dr. HART then opened a discussion on the appointment of a Pathological Committee by the Society. After regretting that many valuable specimens, and also that much pathological knowledge, was lost under the present regulations of the Society, Dr. Hart pointed out that in Vienna and other Continental countries pathological examinations were made by special officers, who were bound by law to remove and examine the pelvic organs in each case. He indicated further the great value of pathological work as shown in the recent advances in the pathology of the cervix. Treatment in gynecology was always, unfortunately, in advance of pathology. There were, moreover, so many subjects of dispute in pathology, that all material coming before the Society should be utilised. In this way, he had no doubt, there would be advances made in pathology. He then took up the question of how this Committee was to set about its work, and, in conclusion, indicated the nature of the preparations wanted—only parts removed by operation, ovaries removed in Battey's operation, female fetuses, menstruating uteri, pregnant uteri, &c.

The Council proposed Drs. Buist, Chapman, Murray, Foulis, Underhill, and Hart as the Committee; Dr. Berry Hart to be convener.

Dr. CARMICHAEL stated that other societies had found it necessary to appoint such committees, and the idea met with his entire approval.

Dr. PETER YOUNG thought there could be no difficulty in the appointment of such a committee, individual rights in such specimens not being interfered with, the possessor being allowed to make his own remarks and give a description himself of the specimen.

Dr. CHAPMAN suggested that the Fellow sending the specimen should become one of the Committee for the time being.

Dr. CRAIG objected to Dr. Chapman's suggestion, and stated that the Committee would have the full confidence of the Society, and that a mutual arrangement between the exhibitor and Committee might be made.

Dr. CROOM seconded Dr. Chapman's motion, and held that the exhibitor ought to have full power over his specimens.

On the suggestion of Dr. CARMICHAEL the matter was referred to the Council to frame by-laws as to the duties of the Committee and other matters of detail.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, DECEMBER 1, 1882.

The President, Dr. HART VINEN, in the chair.

Dr. THUDICHUM on the

CHEMICAL DISEASES OF THE BRAIN AND SPINAL CORD.

In this paper the author described the chemical changes of the nerve centres in such diseases as chronic alcoholic infiltration, softening of the brain, locomotor ataxy, and "cerebral glycosuria." No treatment, he contended, was rational in such cases which was not directed to the central nerve lesion; and if that lesion was chemical, the remedy must be chemical also. Locomotor ataxy, he held, was a disease in which took place a gradual destruction of colourless nerve fibres, and a formation of bodies termed amyloid bodies, which gave a reaction similar, but not identical, to that given by starch granules. This amyloid matter was closely related to, perhaps identical with, cellulose. There was no similarity between it and the amyloid degeneration of the liver, which gave rise only to a brown discolouration with iodine. In locomotor ataxy there also might or might not be increase of fibroid tissue. The disease passed from below upwards with varying degrees of rapidity, and he had known

death to be produced in the shortest case in one year, in the longest in thirty years. The author then proceeded to describe a body which he had isolated from brain matter, in some quantity, namely, phrenosin. Phrenosin formed about five per cent. of the brain by weight. It contained an alkaloid called sphingosin, a fatty acid, neurostearic acid, and some water. In disintegration of the white matter which took place in such a disease as locomotor ataxy, the cerebrose radical was set free and passed into celluline. As to the phosphorized and nitrogenous principles of nerve matter, these were of three classes. In the first class, the proportion of phosphorus to nitrogen was as 1 to 1; in the second class as 1 to 2; in the third class as 2 to 2. The bodies so produced were intimately connected with the production of vital energy. They were formed in every centre of life action, the blood corpuscles included, and a celebrated German philosopher had said there was "no thought without phosphorus." They had an enormous property of becoming colloid by the absorption of water, and became crystalloid again immediately upon the abstraction of water. This powerful attraction for water prevented disintegration. Chronic alcoholic infiltration was to be treated by washing out the alcohol from the tissues by large quantities of water. Natural wines he had found peculiarly useful in this respect. In acute and chronic softening there was accumulation of phosphoric acid and of cholestrin. Lactic acid existed in the brain in the proportion of one-tenth per cent. Its faulty excretion in fevers produced delirium, and it had been said that its accumulation as a result of fatigue produced sleep. In concluding, the author asked his audience to set aside anatomy and consider the brain as a lump of chemical matter, as a celluloid septum or wall, on one side of which is arterial blood and on the other venous blood and cerebro-spinal fluid. The chemical constituents, if present in proper proportions, by their reaction on each other, maintained the organ in a state of health, but if the normal proportion was disturbed some form of cerebral or spinal disease followed. Dr. Thudichum's paper, which was of great length, was abundantly illustrated by diagrams, specimens, and experiments. It was listened to with marked attention, but it was evident, from the slight discussion to which it gave rise, that it had been too learned and abstruse for most to follow, and the President and one or two other gentlemen expressed a hope that the author would be able to render his doctrine practicable by pointing out the exact chemical changes which took place in each disease, and the exact chemical agents to be used as remedies.

Dr. GODDARD ROGERS on a certain

CHALYBEATE WATER.

The use of iron as a tonic, the author observed, was nowhere more marked than in the debility which followed rheumatic fever. This debility was greatly increased by the toxic effects produced by the empirical use of a remedy lately introduced—salicylic acid. Although our knowledge of the pathology of rheumatic fever had increased, the author would hold that our knowledge of treatment had not, and he still agreed with old Dr. Warren that six weeks was needed for its cure. The reputation of our English chalybeate spas was mostly confined to their immediate vicinity. Pyrmont was looked upon as the place whence strongly impregnated iron water must be obtained, and nine-tenths of those who drink it believe that it must be very superior, as coming from abroad, or if they go to the source to drink the water, they are more indebted for a cure to the regular course of life enforced in many Continental establishments than to the healing spring. During the last five years Dr. Rogers had used a remarkably powerful chalybeate water, discovered within forty miles of London, at Flitwick, in Bedfordshire, and its undoubted use to enfeeble rheumatic patients had caused him to speak briefly of rheumatic fever. The Pyrmont water contained 12 grains of iron to the gallon; the natural water of Flitwick 144 grains of oxide and carbonate of iron in the same quantity; and, unlike the Tunbridge and other English waters, it remains intact and active for many months. Dr. Rogers regretted that the use of such a valuable remedial agent had been prohibited by the authorities of the West London Hospital.

Mr. KEETLEY defended the action of the hospital authorities.

NATIONAL INDIAN ASSOCIATION.

Surgeon-General HUNTER, late Principal of the Grant Medical College, Bombay, in the Chair.

A MEETING was held under the auspices of this Association on Tuesday, Nov. 28th, in the rooms of the Medical Society of London, when an interesting paper was read by FRANCES E. HOGGAN, M.D., M.K.Q.C.P., on

MEDICAL WOMEN FOR INDIA.

This paper, with which Dr. Frances Hoggan opened the discussion, was the outcome of a series of papers on the same subject, which had culminated in an article by her in the *Contemporary Review* of last August. That article had excited considerable interest in India, in both native and European lay and professional circles, and she had a large number of communications made to her by eminent members of the profession in India, containing friendly criticisms and advice, which she considered would form a valuable basis for the discussion of the evening. Her original proposal, as contained in the *Contemporary Review*, was that, as nearly the whole of the medical profession in India was more or less maintained by Government, some provision ought also to be made by it for the medical treatment of the native female population, a large proportion of which, in consequence of various special causes, were left practically unprovided for. Some misconception as to her views had occurred through her having quoted the estimate made by Sir Salar Jung, and repeated by Dr. Acland, of the number of medical women that might be utilised in India, her own opinion being that only very few could be immediately provided for, or indeed supplied. The general tenor of the remarks made by her professional correspondents was, to the effect that, while they were certain that there existed a very great need for a few highly-trained medical women in India; the Government was too poor to go to the expense of superadding a female medical service to the already complex and costly medical establishments. It might, however, they thought, be induced to do something if private effort were to first set the movement working, and show both its practicability and the pressing need for it. On this point Surgeon-Major Temple-Wright, writing from Nagpore, in the Central Provinces, was very explicit, and he strongly advised any ladies coming out to attach themselves, for protection, to some mission station, but only as professional advisers, and unconnected with either teaching or preaching. Dr. Harvey, the Professor of Midwifery at the Bengal Medical College, expressed himself in a similar manner with regard to the need of medical women for India, and related that one well-qualified lady medical missionary had lately come to Calcutta, whose help and skill he would often gladly utilise, but was prevented from doing so by her refusal to give help unless allowed "to improve the occasion" for proselytising. The most practical proposal made to her, and which elicited the unanimous approval of the meeting, came from Mr. Kittredge, a prominent and influential citizen of Bombay, who offered, on the part of many of his native friends, to raise a guarantee fund, which would ensure outfit and passage out and home, and provide a minimum salary for some years, sufficient to ensure comfortable living for two or three skilled medical women, in Bombay. They might also supplement their guaranteed salary by private practice. In conclusion, Dr. Hoggan said that even if her proposal for the establishment of a Government service of medical women for India, working in harmony with the existing civil medical service, but co-ordinate, and not subordinate to it, be considered as yet premature, opinions could hardly be divided as to the duty of insisting that State-maintained and State-aided medical institutions, shall no longer refuse to provide medical teaching for such native women students as may desire it. To neglect this would be contrary to the spirit which Government had always shown in dealing with Indian educational and social questions.

In the discussion which followed, Dr. ELIZABETH BLACKWELL led off, by insisting very strongly that any woman who went to India should have, above all things, a thorough practical knowledge of operative midwifery, and not be satisfied with mere theoretical or examination knowledge, which, she feared, was at the present day too much the aim and end of the studies of the younger generation of medical women students.

Mr. PEDDER, of the India Office, testified to the com-

plete reliance that might be placed on any proposal emanating from Mr. Kittredge, and stated that he was authorised by Lord Hartington to express his fullest sympathy with the movement. Mr. Peile, the new member of the Bombay Government, had expressed similar sympathy, and his intention to give the project all the help that lay in his power.

Mrs. HECKFORD related her personal experience of medical work among the women of India, and gave it as her opinion that no medical woman ought to go to India unless under some kind of guarantee.

The Hon. AMIR ALI, as representing the Mahomedan community, considered any guarantee to be quite unnecessary. He and his chief co-religionists and compatriots had given the subject anxious consideration for some time past, and they were convinced that any lady settling in one of the Presidency towns, would, in a year or two, earn an annual income of from £2,000 to £4,000 without much difficulty.

Dr. GARRETT-ANDERSON insisted upon regarding the whole question from its financial aspect alone, and considered a guaranteed minimum salary an absolute necessity; without that she would advise medical women to stay at home, and not go to India.

Surgeon-General FRANCIS deprecated the leaving out of philanthropic considerations, while he condemned the practice which he knew existed among medical missionaries of giving medicine only when it was accompanied by reading a chapter from the Bible; this he considered was proving false to the initial principles of the medical profession.

The Right Hon. JAMES STANSFELD expressed, in a long speech his satisfaction with the progress the question was making; and hoped that ere long native women students would be enabled to acquire a complete medical education in India, which they might use for the benefit of their lay sisters.

The CHAIRMAN (Surgeon-General Hunter), also testified to the need of a guarantee, and pointed to the opposition that medical women would be sure to receive from the unrecognised, but not unqualified, native hakims.

Several other Indian gentlemen also spoke, and the proceedings terminated with a vote of thanks to Dr. Frances Hoggan for her paper.

THE excessive death-rate of 47·8 per 1,000 in a population of 119,000 was registered in Sunderland last week; the deaths exceeding the births by eight. Of these above one-fourth were of children under one year of age, who succumbed principally to measles and scarlet fever.

THE deaths from typhoid in Paris last week registered 79 against 250 six weeks ago. This is, so far as it goes, satisfactory; but these constantly recurring epidemics should be a sufficient indication to the sanitary authorities that the drainage of the city needs remodelling. We advise them to read carefully the discussion on the subject which occupied the last meeting of the Académie de Médecine, and fully referred to in our Paris correspondent's letter of the present issue.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Bolton 14; Wolverhampton, Birkenhead 19; Brighton 20; Salford, Nottingham, Huddersfield 21; London, Edinburgh, Leicester, Norwich 22; Halifax, Cardiff, Derby 23; Manchester, Newcastle-on-Tyne, Sheffield, Bradford 24; Preston, Bristol 25; Blackburn, Liverpool, Birmingham 26; Leeds, Glasgow, Portsmouth 27; Plymouth, Oldham 28; Dublin 29; Hull 32; Sunderland 47.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 6, 1882.

COMING MEDICAL REFORM.

THE British Medical Association, through the agency of Dr. Waters, the President of its Medical Reform Committee, has taken the field for the coming Parliamentary campaign against the current abuses of medical education, and has enlisted the important aid and co-operation of all the important medical newspapers in the kingdom. A deputation composed of almost all the official representatives of the Association, and of the *Lancet*, *British Medical Journal*, and *Medical Press and Circular*, waited last week on Lord Carlingford and Mr. Mundella, at the Privy Council Office, for the purpose of urging the Government to proceed with medical legislation without further delay. Indeed, it can hardly be considered necessary to urge the matter on the attention of the Ministry, inasmuch as the wretched state of medical education and qualification, the imbecility of the General Medical Council, and the unimpeded existence of quack practice everywhere have been inquired into, substantiated, and officially declared by the Royal Commission which sat in the early part of the present year. Before that Commission the Scotch colleges, the effete licensing bodies, and the quacks were fully heard in their own defence and every opportunity afforded them to refute the charges which reformers have brought against them, and yet the verdict of the Commission was dead against them, as that of the profession has been for years past. The facts recapitulated in the statement of Dr. Waters were sufficiently conclusive to convince any one who is willing to learn, and they would convince the profession if it needed to be informed that for years past

a lucrative trade in the granting of diplomas to dangerously incompetent persons has been carried on openly under the eye of the General Medical Council. A few excerpts from Dr. Waters' statement are worth quoting, if only to remind our readers of what is going on in our profession:—

The evidence given before the Royal Commission, said Dr. Waters, has revealed a lamentable state of things in respect of the defective general education tolerated by the existing Medical Council, as shown by the grievous ignorance of English orthography, an ignorance which could not be met with, much less tolerated, in a common village schoolmaster. In my evidence before the Select Committee of the House of Commons, I adduced egregious errors in spelling committed in the course of his examination by a successful candidate for the degree of Doctor of Medicine. I refer to a candidate who spelled height "hight," region "regon," and so forth. In the examination of Mr. T. Cooke, a graduate of Paris, a successful private teacher in London, who prepares candidates for their examinations, he was asked by Professor Huxley:

4979. "Apart from the qualifications required for the B.A. degree, it is a matter of fact, is it not, that a vast number of the young men, when they come to their medical studies, cannot write a decent letter, and have not a notion of English composition?"—"That is the case."

So much for the necessity of improving the preliminary education of the candidates for a so-called learned profession. Now, as regards the granting of licences, entitling to registration as medical practitioners, it is notorious that candidates for the medical profession travel from one division of the kingdom to another, pass the first part of their examination in one division and the second part in another, and by thus, to use a familiar term, dodging different examining boards, gain admission to the *Medical Register*. Attempts have for years been made to establish a conjoint examining board in England. Supposing such a board established, candidates could still, as now, visit another division of the kingdom, and there acquire the coveted diploma, which will enable them to practise in England as well as elsewhere. Supposing one English body left out in any English projected conjoint board, the licence of the excluded body will entitle the possessor to registration, and thereby, however imperfectly he may have been examined, enable him to practise the profession in all its branches. In proof of the inequality of the present examinations, Professors Erichsen and Humphry (Royal Commission, 562, 1155) refer to the inequality of examination in England, as evidenced by the Apothecaries' Society of London. Dr. Jacob shows (1374) that 151 out of 232 Queen's College (Ireland) students obtained their diplomas from the Edinburgh colleges. It turns out that a very large proportion of the Irish students have, within the last fifteen or twenty years, taken their qualifications in Glasgow or Edinburgh.

Mr. Gamgee (of Birmingham) testified: (3229) "With regard to the Colleges of Physicians and Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons in Glasgow, I have known men get through these who had failed in our College of Surgeons repeatedly; and I have no hesitation in saying they were men who were utterly unfit to enter the medical profession. I have asked: 'How is it that A.B. went to Edinburgh or Glasgow? Can you tell me anything about what is the feeling of the students on the choice of examinations?' They have said, 'We know very well that the Scotch colleges give the easiest examination. If a man is plucked here, he can go there and, to use a student's expression, bring his ticket back.'"

3230. "Do you say that with regard to the Colleges of Physicians and Surgeons at Edinburgh?"—"Yes, I do."

3231. "That statement is made upon cases which have come within your own knowledge as a teacher?"—"Yes, I speak of men that are now upon the *Register*. I have

refreshed my memory by looking to see if they are still alive, and I know the men perfectly well."

3232. "Do you think there are many instances of that kind?"—"I know several." He further stated that "It has a most demoralising effect on the students."

Mr. Christopher Heath, F.R.C.S., Holme Professor of Clinical Surgery in University College, London, was questioned as to men who fail to pass the College of Surgeons.

3293. "Where do they generally go?"—"To Glasgow by preference, and sometimes to Edinburgh."

3295. "Have you yourself any knowledge from experience of the Glasgow Faculty?"—"I only judge by the results. I know that men who go up, who failed here, come back with diplomas."

3298. "Could you give us one or two particular instances, without mentioning the names?"—"I may mention one which occurred two years ago. A man was plucked the third or fourth time at the primary examination at the College of Surgeons in anatomy and physiology. He afterwards, at my recommendation, went to Glasgow, and came back with a double qualification."

Dr. Glover said: I see in yesterday's *Times* a case in point. In the list of those passing the examination of the College of Surgeons of England I noticed that of 26 who passed their examination in surgery in that College, 13 of them went down to Edinburgh and passed the examination in medicine. In that case they must either have failed in medicine, or have preferred to take one part of their examination in Edinburgh for a London diploma. That is an instance of the working of the system which has been shown to prevail by Dr. Waters. I hold a Scotch diploma. I am a graduate of Edinburgh, but I also hold the licence of the College of Surgeons of Edinburgh. I feel it a great hardship. This licence is only half a diploma, and it is a diploma that is spoken against. The authorities in London despise it, and hold my qualifications very lightly. I feel personally aggrieved, and I have tried to convince Professor Turner and others that we ought to seek this legislation so as to take away the disparagement which attaches to the holder of a Scotch diploma.

Lord Carlingford: Do you apply this to all the Scotch bodies?

Dr. Glover: To the Scotch corporations, not to the Scotch Universities, which are very strong indeed in examinations now. Unless we are all very much in the wrong, these Scotch licences are not equal to others, and they are spoken of by such careful speakers as Sir James Paget.

Mr. Macnamara: The Scotch graduates form a small proportion of the 25,000 registered medical men. Of that number, 17,000 are English, so that a small minority of the Scotch stand in the way of a change for the benefit of a majority.

Lord Carlingford: What is the state of Irish opinion? Is it in its favour?

Dr. Glover: The Irish practitioners are in favour of it. To these and other representations Lord Carlingford said: The deputation will easily understand that I am not able at this moment, on the part of the Government, to make any announcement whatever. And, on the part of the department, I do not know that Mr. Mundella and I can say more than that we are entirely at one with the deputation in believing and feeling that legislation upon the subject of medical education and licensing—and effectual legislation, too—ought to take place as soon as possible, and we certainly shall be very much disappointed here if that does not take place during the ensuing session. I have had no opportunity yet of bringing the matter before the Cabinet, but I hope to do so before long, and in doing so, what I have heard from you to-day will be a very important element in the matter, and, I think, a very great support to us here.

Mr. Mundella: I should be very glad if we could get the same support all round as is promised us by the British Medical Association. I know that we could pass

the Bill in the House of Lords, but it is quite another thing to pass it in the House of Commons. But this I am glad to recognise, that there is a general feeling in the profession that we did the right thing in appointing a Royal Commission, instead of letting the matter go to a Select Committee, where time would have been wasted in going into complicated matters brought forward by interested witnesses. Now there is no doubt that the report of the Royal Commission has greatly advanced this question, and our only difficulty is as to what will be the order of legislation; and as to that, as Lord Carlingford has said, it is not possible for us to commit ourselves. We do not know, when there is so much pressing business, how we shall proceed. At present everything is at a complete block, but I hope and trust that we shall remove all obstacles, and if we can do anything for you we shall be happy to do so. I have been reading a large amount of literature on this question, and I understand you want a Bill laid on the table of the House. Perhaps the Lord President will enable us to do that, and take a sort of preliminary canter in the House of Lords, so that we may get the thing through the Commons.

We are well pleased to feel that we are justified in interpreting the declarations of Ministers to this deputation as a definite promise that they will seriously and earnestly undertake medical legislation in the coming session if they can hope for the substantial support of the profession. They evidently feel that there is no escape from the necessity to grapple with the Parliamentary influence of the Scotch colleges, and that to do this successfully they will need every help which medical reformers can give them. That help we can unhesitatingly promise them, even though the Government Bill may not be everything that can be desired. We have already said that we look upon the Report of the Royal Commission as weak in its recommendations as to absolute uniformity of examinational standard curriculum and diploma fee throughout the three proposed examination boards, and also far from definite enough in its dealings with quacks, prescribing druggists, and unqualified assistants. In these respects we hope to find the Government Bill better and more thorough than the Report, and, if not, we shall make every effort to amend it. But, even if it should fall short of what is necessary and just in these matters, we feel certain that four-fifths of the profession will give it their warm approval and every influence which they can exercise in its favour. If the measure deals satisfactorily with the Scotch diploma trade, substitutes an executive and earnest Medical Council for the lethargic and distracted body which now misgoverns medical affairs, and gives us such law as will enable quacks to be checked in their nefarious trade, it will deserve the united efforts of the profession to pass it.

The British Medical Association has struck the first blow, and we trust that other bodies will not be backward in joining their forces for the good cause of reform.

PHYSIOLOGY AT OXFORD.

IN spite of the difficulties perpetually opposed to the fulfilment of founders' intentions as regards the study of medicine at Oxford, a steady progress in this direction is perceptible in changes which, however unpalatable they may be to "those in possession," are, notwithstanding, dictated by inexorable necessity. Foremost among recent indications of improvement is the extension of the University Professoriate, following the recommendations of the

Commissioners appointed to report on the two ancient seats of learning at Oxford and Cambridge respectively ; and it is a matter of some importance to the medical profession that the first appointment to be made under the new régime is one directly affecting its interests. We refer, of course, to the election of Dr. J. Burdon Sanderson to the Waynflete Chair of Physiology, the announcement of which appointment we were able to make in our last issue. This professorship is appropriately named after the founder of Magdalen College, inasmuch as the larger proportion of its endowment will be derived from the income of that College, the University supplementing it to a certain extent. Such employment of private funds, long vigorously contended against, is in every way a desirable and excellent arrangement, and cannot fail to result in largely increased advantages to the cause of education throughout the country. The medical profession as a body, moreover, has reason to feel satisfied with the discrimination displayed by the electors in choosing Dr. Burdon Sanderson to be the first incumbent of the newly-created chair. A faithful and devoted servant to science, a highly-skilled investigator, and a foremost leader of the party of research in this country, he is pre-eminently qualified to achieve the difficult task of infusing life and vigour into the somewhat dreary routine that has hitherto characterised the study of science at Oxford.

The Waynflete Professor's labours will be exerted for the benefit of the whole University, and his lectures will be delivered in the new museum buildings, where extensions have been devised to meet the increased strain its resources will have to undergo. The Department of Biology will consequently be divided into two parts, the Linacre Professor presiding over one—the Zoological or Comparative Section—while the Waynflete Professor will have charge of the second. The laboratory of Magdalen College, situate in the Botanic Garden, will, we assume, continue to be used for purposes of instruction in physiological chemistry and histology ; but its limited extent necessarily precludes its employment on any very extended scale either for lectures or for demonstrations. A good deal of useful work has been accomplished there in the past under the direction of Mr. Yule and Mr. Chapman, and it is to be hoped that the benefits thus derived will continue to be accessory to those obtained through University institutions.

Other names besides that of its present occupant have been mentioned in connection with the new Waynflete Chair of Physiology. No one, however, can be found to dispute the excellence of the final decision of the electors, who have undoubtedly consulted the best interests both of the University and of British science by the appointment they have announced. We would fain hope that it will prove the first of a series of important changes, the effect of which will be the restoration to the oldest and best of our Universities of that medical school whose loss is deplored by every one of her true well-wishers.

MEDICAL WOMEN FOR INDIA.

To the question, Are medical women required in India? replies are given in absolute opposition to, and contradictory of each other. On the one hand, the

statement is loudly proclaimed that the condition of women in Indian zenanas is one of misery ; that through the usages of caste they are precluded from consulting medical men ; that thus, by force of circumstances, they are compelled to suffer—perhaps to die for want of medical advice and assistance ; and that this suffering and death would be in a great measure obviated were the services of fully-qualified medical women available. On the other hand, it is asserted that the picture thus presented is overdrawn. That native ladies undergo a great deal of physical inconvenience appears to be admitted ; but they are believed to get over their confinements with more ease and with less mortality than do the women of western and more “civilised” countries. It is also believed that native women in India suffer less from uterine diseases and disorders than their western sisters, and, moreover, that the death-rate among them is by no means greater, if as great, as among the corresponding classes of British women.

The subject is one of pressing importance, and is likely to come prominently to the front both in medical and parliamentary circles very shortly. The paper read last week by Dr. E. F. Hoggan, and the interesting discussion which followed, when compared with the results of experience, indicated that the extent to which the services of American or British medical women have been taken advantage of by inmates of zenanas differs very materially in different parts of India. Thus, whereas one series of reports state that they are frequently sought after by *purdah-nisheen* ladies, other reports indicate that such services never are sought for, or accepted by those ladies. Hence it is clearly unsafe and misleading to assume that because in certain places Western ladies are allowed to exercise their medical knowledge within zenanas, they are so in all. The fact seems to be that only amongst the most “advanced” members of the native community are they thus received. Even when the heads of such families are themselves “advanced” and “Europeanised” to a degree sufficient to command the admiration of the very leaders of the “Progress” party, the circumstance is well known that, as regards their family arrangements, they still remain strictly bound by their traditional usages. Nor can they be found fault with for this, all things considered.

Although in many instances a medical man—be he native or European—does not obtain admittance into the zenana, there is no doubt that in other instances they do ; indeed, an instance in point occurs in which, although a lady doctor was in full dispensary practice in the city in question, yet, when the wife of the nobleman who was the immediate patron of that lady became ill, the civil surgeon—and not she—was called in. It is important, therefore, to bear in mind this typical case.

Another point which presents itself in reference to the present question is this : Do the natives of India really accept as an acknowledged fact the great excellence of our Western system of medicine over their own which we so proudly claim for it? To this query a reply is perhaps indicated in the circumstance that within a very few years back a wealthy native of Bengal made a preliminary offer to establish and

endow a college at Calcutta in which should be taught ancient Hindoo medicine.

The remarks just made indicate the existence of various difficulties which militate strongly against the success, for a long time to come, at least, of foreign medical women in India. But there are other difficulties which concern such ladies themselves. One such difficulty is the age at which they ought to proceed to India. If young, and immediately on obtaining her diploma, a lady must of necessity be professionally inexperienced, and consequently not more useful, if indeed so useful, in the treatment of Indian types of disease as are the native *dhais* nurses and *mule* practitioners, whose knowledge is at any rate practical, whether called "empirical" or clinical. She will, moreover, find herself in a country and among people in every respect alien to the circumstances under which she has been educated and her train of thought formed; in fact, to borrow the term formerly applied to young subalterns of less than three years in India, she will be in the position of a perfect *griffin*. Two dangers to her usefulness will at this time beset her. One of these is the liability to sickness which peculiarly affects young persons recently arrived in that country. Another is matrimony—a condition into which medical women in India have already been known to fall—and the duties connected with which—more particularly as the advent of children becomes repeated—are completely adverse to the general practice of any other profession than that of a wife and mother. If of an age beyond that just mentioned, it may be assumed that the circumstances which induced a lady to leave her own country are not such as are calculated to ensure success abroad. Altogether, therefore, it does not appear that the time has yet arrived when the presence of British and American medical women in India is generally demanded by native society, or is likely to be generally acceptable in that society.

Notes on Current Topics.

Nauseapathy.

THE world owes a good deal that is of a pre-eminently objectionable nature to homœopathy, but it has fallen to the lot of contemporary disciples of Hahnemann to invent and introduce into their *armamentarium* the most practical refinement of humbug possible for human imagination to conceive. It need hardly be said these new "remedies" are of American origin, or that we shall probably ere long find them in the prescriptions of British unscientific practitioners. The composition of the substances is sufficiently indicated by the names attached to them in the "American Homœopathic Pharmacopœia," and from which the *Boston Medical and Surgical Journal* quotes them. They are: *Syphilin*, *bubonin*, *gonorrhin*, *leucorrhin*, *glanderin*, *anthracin*, &c., and the inventors of the filthy compounds unblushingly describe them as "remedies obtained from the morbid products of the animal kingdom," while they dignify them by the titles "*isopathics* or *nosodes*." It is easy to trace the crude and ignorant reasoning which,

arguing along the *similia similibus curantur* line, has led to the manufacture of such disgustingly loathsome productions, but it is impossible to conceive that the most patient and long-suffering, even among the victims of homœopathy will consciously assent to be made a recipient of pathological products obtained from wholly indefensible sources. We trust that any attempt to import these noisome abominations into this country may be met by the punishment such an effort would deservedly call for.

Pay Hospitals.

In his recent work on Pay Hospitals of the World, Mr. Burdett draws attention to the fact that Dublin has given a more extended trial of the system than any other town in the United Kingdom, the Maison de Santé having been established in Charlemont Street in the year 1854, and successfully carried on since that date. Although it has been so long in existence, we believe that its many advantages are not sufficiently known to a large number of medical practitioners throughout the country, and that with increased support its sphere of usefulness might be largely extended. As at present arranged, it is capable of receiving thirty patients, and persons of respectability of both sexes suffering from any form of medical or surgical disease, except insanity, are admitted. The buildings for the reception of infectious diseases are separate and entirely unconnected with the rest of the institution. The payments vary from one to three guineas a week, which include ordinary medical attendance and nursing, board, &c., a private room being obtained for two or three guineas, and a bed in a public ward for one guinea per week. The establishment most thoroughly combines the comforts of home with the advantages of a well-regulated hospital. The patients who avail themselves of it consist in large numbers of persons coming to town for the purpose of undergoing surgical operations, and of students and others who are taken ill in lodgings in Dublin, the infectious department serving a very useful purpose as a means of isolation when fevers, &c., break out in large families or schools. Those who have had to deal with serious disease in lodging-houses and hotels will well know how to appreciate the comforts and efficient nursing obtainable at this establishment. Patients can employ any medical man they may desire; or, should they prefer, they can obtain the services of any of the medical staff without extra payment, except in cases requiring excessive attendance, as, for instance, important surgical operations or special visits. The proprietors have recently made, at considerable expense, great improvements in the sanitary arrangements, and we believe that the establishment is deserving of greatly increased support both from the profession and public.

A Meteorological Antiseptic.

A COLONIAL journal states that a remarkable instance of the beneficial influence of tropical storms has just occurred in the Philippine Islands. The population of Manila was being decimated by cholera, when, at the end of October, a tremendous hurricane swept over the island, almost entirely destroying the town. On the following day not a single case of cholera occurred, and not one has been reported in the island since.

A New Prize.

THE French Government has recently resolved by decree to found a prize, to be called the Prix Volta, and of the value of 50,000 francs, which shall be awarded for the most successful application of electricity, either in the production of heat, light, chemical force, or mechanical power, or in the transmission of messages, or in the treatment of disease. Competitors may be natives of any country, and claiming the reward must be lodged by June 30th, 1887. Subsequently to this date, a Commission, nominated by the Minister of Public Instruction, will consider the character of the several competing claims, and the report delivered by this Commission will be published in full in the *Journal Officiel*. The nature of the contest, and the conditions under which it will be carried out, alike tend to make the matter one of very considerable importance; and as much to medicine as to any of the arts.

The Banquet to the Medical Officers of the Egyptian Expedition.

WE know of no event in the history of the medical profession so pregnant with possibilities as this (to use Dr. Crawford's words) "true 'unification' of the medical officers of the Army, Navy, and Indian Medical Services into the ranks of this great medical profession, and into a brotherhood which is as honourable to the givers as to the receivers." It must bring both pride and balm to the feelings of the medical officers employed in the recent campaign that, at a time when, amid general congratulation, certain subordinate members of the Army, seizing the opportunity of their very early return from the field, unhesitatingly flung against the Medical Department charges of incapacity which, to say the least of them, have been proved to be directly at variance with the opinions of the commanders of the troops, the representative members of the profession have with one accord come forward, not only publicly to proclaim their unshaken confidence in their military brethren, but to afford to those whose duty it is to pronounce opinions on the conduct of all branches of the expeditionary force; an occasion for either eloquent silence or candid testimony; thereby obtaining, as it has proved, for their accused brethren the following certificates—viz., from His Royal Highness the Commander-in-Chief, "that he highly appreciates their valuable aid and good work done;" from Sir Garnet Wolseley that, "individually none are more devoted to their duty;" and from the Secretary of State for War that, "he especially wished to do honour to the medical officers who have served in Egypt with so much distinction and ability." While it must be regretted by all that a royal command should have deprived the banquet of the presence of so many distinguished guests, there can be no question that the foregoing opinions, deliberately penned by those in authority, are of greater weight than the same words courteously uttered amid the usual amenities of accepted hospitality.

If anything could silence the narrow jealousy of small minds such unimpeachable evidence, voluntarily offered, would produce that desirable result, but we do not suppose that we are within measurable distance of the Millennium, and can only congratulate our military brethren on being

in possession of such high credentials that they can afford in future to disregard all puny calumny.

Porro's Operation.

A SUCCESSFUL case of Porro's operation occurred on Monday, the 27th of November, in a house in Islington, Dr. Clement Godson, Assistant Obstetric Physician to St. Bartholomew's Hospital, having undertaken it. The subject was a dwarf, twenty-four years of age, whose pelvis was too hopelessly distorted to admit of delivery by any usual means. She was four feet four inches high, while the infant measured twenty inches in length, and weighed eight and a-half pounds. The time occupied by the whole proceeding was just one hour, and at latest accounts the state of the mother was very favourable, the highest temperature reached being less than 100°, and the pulse-beat never more than eighty per minute. The child is alive.

The late Dr. Spencer, F.R.C.S.I.

OUR advertisement columns contain the list of subscribers to the appeal made on behalf of the widow of the late Dr. Spencer, who died of typhus fever, contracted in the discharge of his dispensary duties, and his being obliged to place the body of his unfortunate patient in her coffin when others shrunk from that duty. Dr. Spencer's delicate health rendered him ineligible for life insurance, and his death leaves his widow totally unprovided for. We trust that the members of our profession will generously respond to this appeal.

Lady Candidates and Medical Examinations.

THE Pass lists of the London University M.B. Examination, lately issued, include the names of two students from the School of Medicine for Women, one of whom obtained a place in the first division of the general list, and in addition, the gold medal and exhibition for obstetrics. This lady, Mrs. Scharlieb, is the first of her sex to gain these highly honourable distinctions; and the present list of Bachelors of Medicine is especially notable on account of its containing such an unusual illustration of the success which may attend the prosecution of medical studies by women. The other successful lady candidate is Miss Edith Shove, who has been placed in the second division. With such examples of what may be accomplished on their part by steady perseverance, and with the opportunities now open to them, to obtain the most desirable qualifications, there is every inducement for female students to enter on the task of preparing themselves for professional practice; and we do not doubt that the positions already gained will be held in the future with a determination that will overcome all obstacles and conquer all difficulties.

The Pathological Section of the Academy of Medicine of Ireland

Met in the Royal College of Surgeons on last Friday evening. An address was delivered by the President of the Section, J. M. Purser, Esq., M.D. Specimens of Hodgkins's disease were shown by Dr. J. Magee Finny and Mr. W. Thomson. The following specimens were exhibited by card:—1. Mr. J. B. Story—Glioma retina; 2. Dr. E. H. Bennett—Fibrous and osseous union of

fractures of the patella; 3. Dr. A. H. Corley—Vesical calculus; 4. Mr. C. Coppinger—Loose cartilage of knee joint; 5. Dr. Foot—Pachydermatocoele, &c.; 6. Mr. P. S. Abraham—(a) The Bacillus of tubercle; (b) Sections illustrating the formation of vessels in granulation tissue; (c) Double fracture of the lower jaw. The following papers were read:—1. Mr. J. K. Barton, President of the Royal College of Surgeons—On Volvulus; 2. Dr. Thomas E. Little—On Aneurism of the Internal Iliac Artery; 3. Mr. W. I. Wheeler—On Nasal Polypus.

Resignation of the Permanent Secretary to the Local Government Board.

IN consequence of ill-health, the permanent secretary to the Local Government Board, Sir John Lambert, has been compelled to resign his post, whereby the services of a highly capable and successful public servant are lost to the country. None will fail to regret the cause which has necessitated this course on the part of Sir John Lambert, to whom, in greatest part, must be attributed the present efficiency of the department with which he has so long held official connection. The responsibilities of such a position are necessarily very heavy, and with no tendency to become less so; the secretary to the Board being required to preserve a constant knowledge of its whole organisation and working, and to keep himself at all times *au fait* with every particular of its administration. The new occupant of the position is Mr. Hugh Owen, whose qualifications for the important post to which he has been called afford the best evidence of fitness to conduct its affairs. He has undergone a long course of training in the offices of the Board, and is, next to his predecessor, probably better acquainted than any other person with the routine and aims of the Health Department of the Government. It cannot be denied that he will have much to do in the way of rearrangement and modification, but there can be no question of the ability which he will bring to bear on whatever task may be confronting him.

A Stinging Tree.

THE *Gardeners' Chronicle* gives an interesting account of the effects of the stinging tree, *Laportea gigas*. The pain produced by the sting of a single hair on the right hand gave rise to remarkable symptoms, the pain being confined to the right side of the body and being succeeded by a numbness and slight paralysis. Besides the pain, a sensation of losing the senses, or rather, of becoming insane, was experienced. The severe symptoms lasted two hours; the spot pricked remaining constantly painful for nearly a month after being stung.

Drug Frauds.

THE *Pharmaceutical Journal* says that at the drug sales last month three bales of false buchu leaves, and five bags of a new buchu with linear obtuse leaves, and also the leaves of *Bursera vulgaris*, were offered. A bag of a bitter bark, some of which has on previous occasions been sold as *Cusparia* bark, was again placed on the market. Seventy-five bags of the stems of *Coccoloba* were offered as Colombo root, and some of the mouldy *ipeocuanha*, mentioned recently, after having been washed and dried, was again put up for auction. A adulterated matico was also offered for sale.

London Hospital Medical Club.

ON Thursday evening last the anniversary meeting of the London Hospital Medical Club was held at the Holborn Restaurant. Mr. James F. Adams, one of the surgeons of the hospital, presided, and was supported by a large number of members and their friends, in all sixty-three. Among those present were Mr. Jonathan Hutchinson, Dr. Langdon Down, Mr. Spencer Watson, Dr. Christie, Dr. Stephen Mackenzie, Dr. Sansom, Dr. Turner, Dr. Gilbert Smith, Dr. Warne, Mr. Waren Tay, Mr. Trèves, Mr. Moullin, Mr. R. Debenham, Dr. Woakes, Dr. Bedford Fenwick, Dr. James Anderson, Mr. Brownfield, Mr. Munro Scott, Warden of the College, and Mr. Rivington (Hon. Sec. and Treasurer). The ordinary business of the Club, including the admission of several new members, was transacted at a preliminary meeting; and after an excellent dinner and the usual loyal toasts, the chairman spoke of the value of the Club in promoting union and good feeling amongst those who had worked, and were working, at the great charitable and educational institution with which they were all connected. The Club was founded in 1838, but an anniversary meeting of the gentlemen educated at the London Hospital was held as long ago as 1792, and very likely before that time, as the London Hospital Medical School was the first complete medical school in the metropolis. Special interest attended the present meeting from the fact that the chairman's father, an able and well-known surgeon and lecturer, Mr. John Adams, was for twenty-four years the popular secretary to the Club. The toasts of "The Chairman," proposed in eloquent terms by Mr. Hutchinson, and of "The Secretary," given by Dr. Christie, were drunk with more than ordinary cordiality, and with all honours. Allusion was made by Mr. Rivington to the loss sustained by the Club in the lamented death of Mr. George Critchett, the most genial of men, and to the increasing prosperity of the Club, as shown by the constant augmentation in the number of members and of the balance in hand (more than £200). The Club was an unique institution, and ought to include every *alumnus* of the London Hospital. At the termination of the speeches, songs were sung by Dr. Gilbert Smith, Mr. Garman, Mr. Appleford, and Mr. Hewkley, and appropriately terminated a very pleasant and successful meeting.

Medicated Ether and Alcohol Spray.

DR. UNNA, of Hamburg, in his anxiety to limit the quantity of iodoform used in individual cases, employed it, dissolved in ether, in the form of spray. He thought he discerned advantages in this method of employment that led him to the trial of other medicaments in solution in ether or alcohol spray. The advantages he thought he recognised were comprised in the following: 1. A more energetic and searching action of the drug, which is driven more deeply by the spray into the tissues, and which reaches more readily out-of-the-way corners by this than by any other method. 2. Much more sparing use of the drug employed than when used as a powder, or in ordinary solution. 3. A soothing effect from the use of the spray. He recommends this form of employment in all parts

difficult of access, either of skin or mucous membrane, external meatus auditorius, nasal and pharyngeal cavities, urethra and rectum, vagina, hairy scalp, &c., or for mucous membranes that are constantly washed by secretions. As examples of the classes of cases in which Unna has employed medicated spray may be mentioned: Solution of chrysophanic acid in ether for herpes tonsurans, favus, sycosis parasitaria, and psoriasis capitis; chloral hydrate ether spray as a local anæsthetic for slight operations, such as the opening of abscesses; iodoform ether spray in soft ulcers and syphilitic affections, wherever situated; iodide of mercury and iodide of potassium ether spray; corrosive sublimate ether spray, or corrosive sublimate carbolic spray, in all kinds of fungoid and syphilitic skin affections; collodium or wax ether spray, for the isolation of ulcerated surfaces lying opposed to each other, and for the protection of parts contiguous to an ulcer to which stronger applications are about to be made, &c.

The Cradle of American Medicine.

PHILADELPHIANS are advancing the claims of their city to be regarded as the cradle of American medicine. The first practical instruction in anatomy in America was by Dr. Thomas Cadwalader, in 1750; the first permanent general hospital was founded there in 1752; the first clinical instruction in America was given there by Dr. Thomas Hurd in 1766; the first medical library in America was founded there in 1763; the first medical society in America was organised there in 1766; the first medical dispensary in America was established there in 1766; and the first American medical college was organised there in 1765.

Deaf-Mutism.

DR. HEDINGER, of Stuttgart, has recently published a report on Deaf-mutism and the Institutions for Deaf-mutes of Baden and Würtemberg, for an account of which we are indebted to the *Deutsche Med. Zeitung*. The author has taken for the motto of his work an expression of Wilhelmi, to the effect that the statistics of deaf-mutism should have for their aim not a mere numbering of the unfortunates who are the subjects of these affections, but that they should be mainly employed as a means of searching out and verifying the causes. He makes free use of Wilhelmi's writings. From the statistics already published by Wilhelmi, we learn that mountainous districts afford the greatest number of deaf-mutes, and plains the smallest; that the proportion of males to females affected is as four to three; and that, contrary to the views of Voisin and Child, the offspring of marriages of persons near akin afford 10 per cent. of the whole number, independently of 5 per cent. of the blind, and 15 per cent. of those afflicted with mental disorders. Amongst the causes of congenital deaf-mutism are adduced disparity of ages in parents, especially greater age of the mother, sicknesses, constitution (scrofula), imperfect procreative power, sickness, excitements, &c., during pregnancy, direct hereditary transmission, and drunkenness on the part of the parents. Amongst the causes of acquired deaf-mutism brain diseases occupy the most important place; thus, of Wilhelmi's cases, 29.5 per cent. had their origin in brain affections, convulsions, &c., and 25.05 per cent. in cerebro-spinal meningitis. That every epidemic of this disease crowds

the institutions for the deaf and dumb is a well known fact. His reports of autopsies are few in number, but interesting. They only comprise five cases. In four the semi-circular canals were occluded, or otherwise abnormal; in one case the posterior half was absent. As regards hearing power, the statistics of the Baden and Würtemberg institutions, taken in conjunction with those collected by Toynbee, give the following results:—1.5 per cent. could hear words; 3.6 per cent. could hear the voice; 22.9 per cent. could hear sounds; 72.0 were absolutely deaf. The author considers it wrong to leave a child who is hard of hearing, or who can even scarcely hear at all, to its fate, but maintains that every care should be bestowed upon its treatment, and that no child should be handed over to a deaf and dumb asylum until a skilled specialist has pronounced its case to be incurable. The advantages of the German method of educating deaf-mutes, which consists (as every one is now aware) in teaching them to speak vocally, over the method in use in France and England (sign-talking), are ably discussed, and, one might safely imagine are sufficiently obvious even without skilful advocacy.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE EDINBURGH OBSTETRICAL SOCIETY AND PATHOLOGY.—The step taken by the Obstetrical Society in appointing a pathological committee to report on specimens presented at the meetings of the Society is certainly an advance in the right direction. Hitherto the products of disease have been simply placed on the table with merely a word or two as to their nature, no discussion taking place regarding them. The same system is adopted in the Medico-Chirurgical Society of Edinburgh. It is a pity that the two societies do not unite, surgical, obstetrical, and pathological questions being discussed in sections devoted to each. Much valuable pathological work is undoubtedly lost by the isolated position of the two societies. The united Transactions would be of more value, and would induce country practitioners to contribute. The formation of a pathological society would be only the multiplication of segments, to which we object, but Edinburgh could well support a society publishing one volume of Transactions in which clinical medicine, surgery, pathology, and obstetrics each added their share to the general fund of information. The societies of Dublin having set an excellent example of union into one "Academy of Medicine;" we commend the same to the consideration of the two societies before mentioned.

THE NEW FEVER HOSPITAL, EDINBURGH.—The first meeting of the newly-constituted Public Health Committee of the Edinburgh Town Council, held last week, was largely attended. Councillor Clark was unanimously reappointed convener. The first matter under consideration was the disposal of the Old Infirmary buildings. Mr. Morham, the City Superintendent, was in attendance, and explained, by means of plans, &c., the former decisions of the committee as to the amount of space which would be required for the infectious diseases hospital. Ultimately a unanimous approval was given to the scheme of the late committee—namely, that the whole of the surgical hospital should be retained for the purpose of a city fever hospital, in which those forms of infectious disease should be treated which are not treated in the adjoining fever hospital belonging to the managers of the Infirmary.

EPIDEMIC OF FEVER AT ABERDEEN.—An epidemic of fever is at present raging in a low-lying district in the east end of Aberdeen. Nearly thirty patients are at present lying in the Royal Infirmary. The sanitary authorities have taken all necessary steps to prevent the spread of the disease by disinfecting the houses in which the cases have occurred. One has been shut up altogether; the rest have been cleansed.

GLASGOW MATERNITY HOSPITAL.—The annual meeting—and, we may add, the annual squabble—of the General Court of contributors to the Glasgow Maternity Hospital was held on the 28th ult. in the hospital, Mr. Richard R. Grant in the chair. Dr. Miller, physician to the hospital, read the medical report for the year ending the 15th inst. From this it appeared that 256 cases had been treated in hospital and 1,254 at the homes of patients, or a total of 1,510, an increase on the number last year of 260. Only 23 nurses had received training in the hospital. While this number was below that of last year, the class of women was much superior. There was a considerable increase in the number of students, no fewer than 154 having joined. Professor Leishman spoke decidedly in favour of the management of the institution. He had changed his mind as to the usefulness of maternity hospitals. Referring to Continental hospitals, he remembered how, when puerperal fever got into them, it rapidly spread and sacrificed maternal life to an alarming extent. He was glad to say that he had lived to change his views on the matter, and the views of other people were changed as well. Antiseptics had been brought into such general and thorough use that there was now comparatively little danger of the alarming malady to which he had referred.

DECREASE OF FEVER AT JOHNSTONE.—The fever at Johnstone has now reached a climax, and is rapidly decreasing. There have in all been between 60 and 70 deaths, but very few fresh cases are reported by the medical gentlemen.

GLASGOW WESTERN INFIRMARY.—The eighth annual general meeting of qualified contributors to the Western Infirmary of Glasgow was held in the Religious Institution Rooms on the 30th ult., Sir James Watson presiding. Mr. Henry Johnston, the secretary, read the annual report, of which the following portion referred to the patients:—The number of patients treated from 1st of November, 1881, till 31st October, 1882, was: Out-door patients, treated in surgical wards, chiefly for accidents, 873; treated in Dispensary—medical cases, 7,298; surgical cases, 5,257; women for special diseases, 889; for diseases of the ear, 1,066; for diseases of the teeth, 322; for diseases of the throat, 264; vaccinated, 701; midwifery cases, 25—total, 16,895. In-door patients—Remaining in hospital at 31st of October, 1881, 310; new cases admitted, 3,855—total, 3,665. Of the in-door patients, numbering as above, there were dismissed well, 1,253; greatly improved, 583; improved, 704; not likely to be benefited by longer residence, &c., 576; died in hospital, 244; remaining in hospital at 31st October, 1882, 305—total, 3,665.

DUMFRIES.—AN OUTBREAK OF FEVER.—For some time past fever has been prevalent in Dumfries and Maxwelltown, but principally in the latter borough. The managers of the Infirmary having declined to receive more than a certain number of patients in the ward appropriated to infectious diseases, and there being considerable room in the building not occupied, the Dumfries Local Authority asked Dr. MacLagan, Edinburgh, to examine the Infirmary and report. He has made some important suggestions, to consider which a general meeting of Governors has been called. In Dum-

fries eight patients sent to the Infirmary were from one household, which is the number the weekly committee have, in the meantime, intimated they will receive. From Maxwelltown there have been five applications for admission.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 25th ult., were at the rate of 28 per 1,000 per annum, against 29 in the preceding week, and 21, 29, and 19 in the corresponding periods of 1881, 1880, and 1879.

THE HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 25th ult., was 94, and the death-rate 21 per 1,000. Diseases of the chest accounted for 50 deaths, and zymotic causes for 8, of which 1 was due to fever, and 4 to scarlatina—the intimations of these diseases being respectively 19 and 44.

POLITICO-RELIGIOUS INTRUSION INTO MEDICAL AFFAIRS.

THE *Dublin Freeman's Journal* has, within the past week, tried to apply to the Irish Academy of Medicine the policy of politico-religious discord, which has stood that journal in good stead on many other occasions when it was desired to break up an effort for good because that effort was not according to the views of that journal. On this occasion the attempt is the more to be regretted and despised because every one who is conversant with the truth of the matter knows that there is not, in the charge that the Academy has practised religious exclusion, even the fraction of truth which commonly serves the *Freeman* for a text. The following is the editorial passage to which we refer:—

"Now comes the discreditable part of the affair. Every member of one of the original societies who desired to join became a member of the new organisation without election, and every member was therefore equally eligible for election upon the governing body. A little clique, however, assembled, and sent out what is commonly called a 'house list.' On this list they only placed a limited number of names of their own nominees, twelve, we believe, in the case of the minor councils, thus conveying, and we believe, indeed, that the circular accompanying the last asserted that the choice of members in the ballot was limited to ten out of these twelve nominees. This was a flagitious, and we doubt if it was not an illegal, proceeding. The names of the men thus sent around were nearly all Protestant, and the result has been that on the general council not one single Catholic has been elected, and that on the departmental councils there are only one or two in each case."

Now the real truth is as follows:—When the Academy was in course of formation the members of all the professional societies in Dublin were invited to attend the preliminary meetings, and did so with absolute freedom of every politico-religious consideration whatsoever. Three of the societies joined in the movement cordially. The fourth—the Obstetrical—though its members had almost unanimously approved of the movement, was placed by its Council in a position of antagonism to the Academy, and some of the leaders in that hostile demonstration happened to be Catholics. When the organisation of the Academy had been completed, circulars were sent out which invited all members of any of the societies who contemplated enrolling themselves as Fellows of the Academy to send in their names if they desired to become candidates for seats on the Sectional Councils. This invitation included every Fellow of the Colleges of Physicians and Surgeons, and almost every practitioner of note in Dublin; and it was open to every Catholic physician or surgeon to come in as a candidate as a matter of right. It would seem that very few applicants

of any kind forwarded at first their names for insertion on the lists, partly, as we think, because the period before the election was only a few days; partly because many had not made up their minds to join as Fellows; but chiefly because individual members hesitated to submit themselves to election, fearing a severe contest and possible unsuccess. Thus it happened that when the lists should have been printed there was an altogether insignificant number of applicants, and it became necessary for the provisional officers of the Academy to consider for themselves the persons most deserving to be placed on the Sectional Councils. They therefore made, strictly for their own information, four such lists of ten names each, and naturally those lists did not contain the names of those members of the Obstetrical Council who had opposed the formation of the Academy.

We are in a position to deny absolutely that these lists were either printed or circulated, or any influence used to carry them, but they were shown for approval to a few. Meanwhile, names had been sent in, and amongst the rest a list of fifteen names suggested for a Council of the Obstetric Section, including therein the names of the hostile persons. Every name so sent in was fairly submitted to a ballot vote of the whole Academy, numbering about 150 Fellows, and including a large number of Catholics. And what was the result? For the Pathological Council, there being only ten applicants, all were elected, including one Catholic. For the Medical Council two candidates, both Protestants, were rejected, and the only Catholic who offered himself was elected. For the Surgical Council four candidates, all Protestants, were rejected, and the only Catholic who offered himself was elected. For the Obstetrical Council five candidates were rejected, three of whom were Protestants. Of these, two Catholics and one Protestant who had been prominent in the opposition to the Academy were thus excluded, while another Catholic who had supported the Academy movement was elected by a good majority. Thus it is seen that of twelve rejected candidates ten were Protestants, and two Catholics, while of six Catholics who offered themselves four were elected. The three gentlemen, Catholic and Protestant, who were refused admission to the Obstetric Sectional Council, were so refused because they were known to be hostile to the Academy, and we believe that the profession will be of our opinion that, under the circumstances, they had nothing less to expect.

Having thus exposed the absolute falsity of the accusations made by the *Freeman* we may, we hope, venture to dismiss the politico-religious aspect of the Academy from consideration. In truth, we feel heartily ashamed to have found it necessary to follow an ultra-party newspaper into the narrow corner in which it lives and into which it seeks to drag scientific and professional affairs. We have done so because we fear that there may be some of our profession who might take the *Freeman's* statements on such a subject for gospel, and be thus led to misconceive the character of the Irish Academy of Medicine, and we therefore think it right, not only to state the facts, but to express our firm conviction that the recent elections were absolutely free from any shadow of influence, religious or political.

MR. FAWCETT'S ILLNESS.

WE understand that the serious illness of the Postmaster-General presents many features of unusual interest, foremost among these being the complete absence of anything like the typical temperature curve of typhoid fever, the thermometer showing for the most part 103° F. pretty steadily for some

days, and then being higher in the morning than in the afternoon. That there is true typhoid fever, in addition to moderately severe pharyngeal diphtheria, would seem to be certain by the character of the diarrhoea, by the abundant roseolous rash, and by some tumidity of the abdomen. We are glad to know that the diphtheria is passing off, and that the typhoid symptoms are so far not very severe.

THE FEES TO PRESIDENT GARFIELD'S PHYSICIANS.

WE learn by telegram that the board which was appointed to consider and report upon the claims arising out of the late President Garfield's illness have recommended that the following fees be paid to the physicians engaged in the case:—To Dr. Bliss, 6,500 dols.; to Dr. Agnew, 5,000 dols.; to Dr. Hamilton, 5,000 dols.; to Dr. Reyburn, 4,000 dols.; to Dr. Boynton, 4,000 dols.; and to Dr. Edson, 3,000 dols. These, as well as other claims made upon the Government, are much reduced from the original amount.

Literature.

THE SURGERY OF THE RECTUM. (a)

AMONG the many literary undertakings with which the medical press at present teems, there are few that deserve a warmer recommendation at our hands than the present new edition of Smith's work on the rectum. Mr. Smith, a surgeon of great experience, has presented to his readers the fifth edition of his book, which is a fair proof that the matter and information therein contained has been fully appreciated. It is written in a plain, practical style, and gives a vast amount of information on the surgical diseases of the rectum, including the result of the author's lengthened experience, and the necessary treatment to be carried out in each case. We strongly recommend this work, feeling sure that it will prove a useful and practical guide to the special diseases affecting the rectal canal.

MECHANICAL DENTISTRY. (b)

IN writing of the first edition of this work we bestowed on it somewhat faint praise in stating that it was one of the best works on the subject hitherto published, for we remarked we were not acquainted with any book of the kind possessing more than trifling value. It is impossible to teach the practical processes of dental mechanics by means of books, and it is not necessary so to teach them, inasmuch as every dental student is obliged in his professional education to devote three years in acquiring a practical acquaintance with this department of his calling. Chemistry and metallurgy of dental mechanics, of course, can be learned from books; but as separate works exist on these special subjects, they are not needed, although they are included and form a great part of works of the kind before us. Mr. Hunter's book is, however, of sufficient value to make it worth a place in the library of those dentists who like to possess all that is in any way useful in the literature of their department.

Correspondence.

AMERICAN DIPLOMAS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—While agreeing most cordially in your remarks on the above in your issue of the 8th ult., may I be permitted to offer a few observations on the subject.

In America there are colleges and colleges, and unfortunately for the profession in American, some of the qualifying bodies are purely and simply institutions for the

(a) "The Surgery of the Rectum," comprising the Lectures on Surgery delivered before the Medical Society of London, 1865. By Henry Smith, F.R.C.S., Professor of Surgery in King's College. Fifth Edition. London: J. & A. Churchill, 1882.
(b) "Mechanical Dentistry." By Charles Hunter. London: Crosby Lockwood and Co. Second Edition, 1882.

manufacture of quacks. From my experience of American institutions I can say fearlessly that America possesses some of the highest, as well as some of the lowest, types of qualifying bodies.

The University of Pennsylvania which I had the pleasure of visiting during a visit to the United States a short time ago is equal, if not superior, to any I know of. Its staff is made up of men second to none, and its teaching arrangements are made as near as possible to the highest models in England and Europe. Its hospital teaching is conducted in a high class hospital in direct connection with the University. The curriculum of the Medical Faculty of the University is as full and comprehensive as in any of our own colleges, and the chemical, histological, and pathological laboratories are, in themselves, well worthy of the highest praise. The University is a handsome out stone building standing in its own grounds, and separated by a broad drive from the University hospital. The dissecting room is lofty, spacious, and constructed on principles of the strictest sanitation. When I visited it the temperature was close to 90° Fah., and, though dissections were being carried on I did not notice anything offensive. The students engaged in dissection appeared fully impressed with the necessity of careful and thorough dissection. I cannot pass from this subject without saying that, from all the gentleman connected with the University and hospital staffs, with whom I came in contact, I received the greatest kindness and consideration.

In the city of Philadelphia there exists an institution known as the College of Physicians, the membership of which is the real test of the resident medical men's respectability as it admits to its membership only those men who have taken degrees in regular medical colleges after a full curriculum and examination. The College of Physicians is the home of the Medical Society of the State, and contains lecture rooms, library, reading room, and is a handsome well-built structure. In its reading room I found copies of the principal journals of Europe and America.

I also visited the Pennsylvania Hospital which is an important institution containing all the most improved arrangements for hospitals. The methods for keeping the temperature down in summer and up in winter are highly interesting, and I felt called on to say that I was greatly interested and pleased with all I saw.

Unfortunately I had not time to visit the Episcopal Hospital which I believe would have repaid the trouble, as I was informed that it was a first-class institution.

The Jefferson College is the only regular qualifying body beside the University, and this I was unfortunately unable to see, as I was compelled to return to New York before I could get through it.

There are, I believe, some other bodies in Philadelphia who confer degrees and propose to teach medicine, but as they are not regular bodies I shall not speak of them.

Now, Sir, that I have given a rough sketch of one regular American college and its hospital connections, I think we need not fear that the profession would be injured by the admission of the graduates of such institutions to the Register. The difficulty would be in knowing who was who. But, before the graduates of the general run of American colleges were admitted to the Register I should hope the Register was done away with. I would propose that before any foreign graduate was admitted to register, that his diploma should be attested by the British Consul of the city or state in which his college was situated, and that he should be admitted to an examination such as at present is in vogue at Durham University for men of fifteen years' standing, or something of that kind. At present the state of medical education in America, with the honourable exception of a few colleges, is simply deplorable. The competition among the so-called colleges all over the country, the under-selling and under-teaching is simply heart breaking to the professors of the regular and high class universities. The University of Pennsylvania has for years taken a foremost place in the fight against corruption, and stands out honourably and strongly in the clear light of professional dignity and universal respect.

I am, Sir, yours, &c.,

Whitwick, Leicester.

WILLIAM DONOVAN.

[It is, we hope, unnecessary for us to repudiate any intention to depreciate the value of the degrees granted by the University of Pennsylvania, or other American institution

of equivalent rank. Such foreign licensing bodies ought to be recognised, and their *alumni* admitted to practise in Great Britain; but it is our contention that—in the making of a law for such recognition—nothing should be left to the discretion of the Medical Council, which has shown itself devoid of any such quality. There are two propositions of law for the recognition of foreign degrees—the first, that the individual possessing the degree shall apply to the Medical Council to be admitted to practise in Great Britain, and shall be accepted or rejected upon the merits of his particular case; this is the proposal contained in the last Government Bill, and it would give the Medical Council the power to admit any applicant, no matter what his professional attainments might be, without any inquiry into the status of the College which graduated him. The second proposal is that embodied in Lord Ripon's Bill, which passed the House of Lords some years ago. It is that, when application for admission to British practice was made, the Medical Council shall weigh the status of the licensing body which granted the degree—shall satisfy itself that that degree represented an amount of knowledge *not less than that required* for a British registrable licence, and that, if it be so satisfied, all diplomas granted by the same institution shall be recognised as entitling the holder to registration. This is the proposition which we advocate, because it would debar the Medical Council from jobbing for the benefit of any candidate, and would ensure that the Council shall not accord recognition to any foreign diploma unless that diploma was at least as good as the home qualification. We think, moreover, that no foreign diploma should be accepted under any circumstances unless it conferred full legal authority to practise in the State in which it is granted. This proviso would exclude all foreign degrees until they had received the *imprimatur* of the Staats-Examen.—ED.]

Liebig's Extract of Meat.—It certainly would appear from recent decisions that some further attention to the trade marks question is called for, and on considering same it seems desirable to compare our law with that of the Continent. To the medical profession it is a point of great importance that when they advise the employment of certain preparations by their patients there should be no misgiving as to the patient's purchasing the right article. These remarks are based upon the judgment just given in the action of the Liebig's Extract of Meat Co. v. Anderson. In the case in point the name of Baron Liebig was attached to the extract sold by the defendant in pots bearing the likeness of the late Baron Liebig, and upon this the Company and the Liebig family brought an action against the vendor to restrain the sale by him of extracts of meat under the title of "Baron Liebig's Extract of Meat," upon the ground that the article manufactured by the Company had attained a great and distinctive reputation by reason of its being manufactured under the control and subsequently before being sold to the public analysed by the late Baron Liebig, and since his death by Professor Pettenkofer and the present Baron Liebig, and that a certificate of genuineness was attached to each pot, and that the sale by the defendant under the title of "Baron Liebig's Extract of Meat" was calculated to deceive the public into the belief that when they purchased the defendant's article they were purchasing that manufactured and sold by Liebig's Extract of Meat Company. Judgment was, however, after a trial extending over several days, given in favour of the defendant, upon the ground that the Company had no exclusive right to the name of Liebig or Baron Liebig, and that the defendant's pots were not calculated to deceive. Sometime since a similar action was brought in Paris against some dealers in extract of meat for using the name of Liebig. Judgment there was given in favour of the Company upon the ground that the Company had made a reputation by its personal connection with Baron Liebig, and that, until the Baron himself had withdrawn permission to use his name from the Company, no one had the right to adopt it. It was perfectly open to vendors of rival

extracts to say that their article was prepared according to the method of Baron Liebig, but not to call them "Liebig's Extract." It clearly follows that, according to the English law, a man might prepare an inferior sort of extract similar to carpenters' glue and call it Liebig's Extract of Meat, and a physician ordering his patients to take "Liebig's Extract" might be more puzzled by the result of their taking the inferior article than a joiner would be! By the French law it is clear that such a result would be impossible, and it therefore does seem to us that medical men, as well as the trading community, should unite in demanding that protection should be given to the public, by securing to the manufacturers the sole use of any name or symbol under which a thoroughly reliable article has gained a high reputation.

Notices to Correspondents.

MISSING NUMBERS OF THE "DUBLIN MEDICAL JOURNAL."—Five shillings each will be given for the numbers of the *Dublin Journal of Medical Science* for February and March, 1840, if sent to the Dublin Office of this paper, 3 Molesworth Street.

Q.—Apply to the Local Government Board. We do not possess the information.

AN ANTIDOTE FOR PHOSPHORUS

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Could you or any of your readers kindly state if there is any antidote for phosphorus-poisoning? I think I have read somewhere that lime-water is; but I cannot find anything in the text-books. Children are so apt to bite the heads off matches; I conclude in such a case, to drink plenty of cold water, if they would take it (as it is not soluble in water), and give an emetic would be the best course.

Yours truly,
G. S. N.

[In reply to our correspondent, we know of no positive antidote to that substance, though oil of turpentine has been thought by some to possess antidotal properties for that poison, provided it is given sufficiently early; but in cases of poisoning by phosphorus, its prompt removal from the stomach by emetics, such as those of the sulphate of zinc (20 grains in water), or sulphate of copper (3 grain doses in water every five minutes till vomiting is induced), or the stomach-pump, if at hand, should form the chief points of treatment.—ED.]

ALOPECIA.—Dr. Neligan was in the habit of giving the following prescription when desiring to promote the growth of hair, and it is still frequently employed with good results:—

R Tinct. cantharidis, f. ℥j.
Aque sambud, f. ℥ij;
Ess. rosamarin, f. 3vj. Misco; fiat lotio.

DR. R. A. H. (Dublin).—The work is substantially the same as the previous edition, which we reviewed at length. We are happy to confirm your judgment in the matter.

DR. MERCIER (Stone) will please receive our best thanks.

DR. J. O. F. (Durham).—We fear that the insertion of your letter would be much more likely to hinder than further the progress of medical reform. Our action from the first has been perfectly consistent, and our expression of "the mulish hindrance of the irreconcilables" is justified in the eyes of every moderate and right-thinking man. The importation of Arabi Pasha, Egypt, the Arrears Act, &c. into a letter, for which you demand insertion in a medical journal does not quite coincide with our views of the "dignity" to which you refer, and precludes altogether its chance of publication.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

A SPECIAL general meeting of the Society was held on Friday, November 24th, to confirm certain alterations of the bye-laws that had been approved at a special general meeting, held November 3rd. The President, Sir George Burrows, took the chair. The chief alterations made in the bye-laws were as follows:—

The sum required to qualify as an honorary member was reduced by ten guineas; the proposals for membership and the declarations of the widows and orphans may now be signed by two registered medical practitioners instead of by two members of the Society; the admission fee was abolished; the income of the widow eligible for relief was raised from £50 to £30, and certain powers were given to the directors to make extra grants under special circumstances. The age of the orphan eligible for relief was raised to 16 years, and in the case of complete orphans, to 18; and the amount of income of orphans was also increased. In the case of a widow of a member marrying, the child ceases, under the new bye-laws, to have any claim on the Society.

SINGLETON'S OINTMENT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In answer to your correspondent's query as to the composition of Singleton's Golden Ointment, I think that he will find a good substitute—if it be not, as I believe it to be, the identical thing—in 10 gr. of the yellow oxide of mercury, carefully levigated with 2 dra. of fresh butter, or, better still, benzoated lard. This ointment will answer every purpose of the expensive and often rancid *Singleton's Ointment*. The same substance made into an ointment with cold cream is "Payanstick's ointment," so useful in cases of penetrating ulcer of the cornea.

JAMES MARTIN.

MEETINGS OF THE SOCIETIES.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—This evening (Wednesday), at 8 p.m., Dr. Edward C. Seaton, "On the Influence of Small-pox Hospitals, illustrated by the recent behaviour of Small-pox in Nottingham."

OBSTETRICAL SOCIETY OF LONDON.—This evening, at 8 p.m., specimens will be shown by Dr. Cleveland, Dr. Edis, Dr. Galabin, and others.—Dr. Hopkins Walters, "On a Case of Post-partum Avulsion of the Uterus, Right Ovary, and Fallopian Tube; followed by recovery."—Dr. A. Wynn Williams, "On a Case of Ruptured Perineum; improved method of operating."—Dr. Edis, "On a Case of Epithelioma of the Cervix Uteri, Pregnancy, Caesarean Section; recovery."—Mr. J. Knowles Thornton, "On a Case of Extirpation of Uterus and Appendages for Epithelioma of the Cavity."

HARVEIAN SOCIETY OF LONDON.—Thursday, Dec. 7th, at 8.30 p.m., Continuation of the Harveian Lectures: Mr. Henry Power, "On Ophthalmic Medicine and Surgery in relation to General Practice."

CLINICAL SOCIETY OF LONDON.—Friday, Dec. 8th, at 8.30 p.m., Mr. Godlee, "On Three Cases of Intussusception in Infants treated by Abdominal Section."—Dr. Coxwell, "On the Case of a Child with Symptoms resembling those of Myxodema (patient will be shown)."—Mr. Nunn, "On a Case of Necrosis of the Hyoid Bone and Larynx."—Mr. Davies-Colley, "On a Case of Enormous Enlargement of the Lower Lip, cured by Operation."—Cases of Pseudo-hypertrophic Paralysis in Adults will be shown by Dr. T. H. Green and Dr. J. K. Fowler.

ACADEMY OF MEDICINE IN IRELAND.—Friday evening, Dec. 8th. The President of the Surgical Section (J. K. Barton, President of the Royal College of Surgeons), will deliver an address.—The following specimens will be exhibited by card:—Mr. Keasal Franks—1. Excision of the Knee; 2. Amputation of Thigh for Acute Suppuration of the Knee Joint; 3. Amputation of Thigh for Osteitis of Knee-Joint.—Mr. H. G. Croly—1. Urinary Calculi; 2. Medullary Sarcoma.—Mr. A. Benson—Fragments of Calcareous Cataract dislocated into Anterior Chamber.—Mr. Stokes—1. Medio-Tarsal Amputation for Epithelial Ulceration of Great Toe; 2. Syme's Amputation for Caries of the Tarsus; 3. Supracondylar Amputation for Atrophy of Leg and Extreme Deformity (Varus) of Foot; 4. Teale's Rectangular Amputation of Thigh for Chronic Disease of Knee; 5. Teale's Rectangular Amputation following Excision of the Knee-Joint for Caries; 6. Amputation of Thigh (Antero-posterior flap) from Necrosis of Leg Bone.—The following papers will be read:—Mr. O'Reilly (Trim), "Case of Nephrectomy."—Mr. J. F. Knott, "Case of Dissecting Aneurism of the Aorta."—Mr. H. Fitzgibbon, "Use of Anesthetics in Rectal Surgery."—Mr. Wheeler, "Trephining in Caries of the Mastoid Process."

Vacancies.

Chipping Norton Union.—District Medical Officer. Salary, £65, with the usual medical fees. Applications to the Clerk on or before Dec. 25th.

West Bromwich District Hospital.—House Surgeon. Salary, £30, with board, &c. Applications to the Hon Sec. on or before Dec. 9th.

Appointments.

BRADSHAW, T. R., M.D. Dub., Resident House Surgeon to the Liverpool Royal Infirmary.

CRENN, P. J., M.D., Physician to the Cork North Infirmary.

GRACE, C. E., M.R.C.S., Resident House Physician to the Liverpool Royal Infirmary.

HIGGINS, C., F.R.C.S. Eng., Ophthalmic Surgeon to Guy's Hospital, Ireland. W. W., M.D., Medical Officer to Miss Mary Murray's Hospital for Girls, near Prestonpans.

JONES, D. L., M.R.C.S., Resident Assistant Surgical Officer to Charing Cross Hospital.

LOWE, T. E., M.R.C.S., Resident House Physician to the Liverpool Royal Infirmary.

SPENCE, W. J., L.E.C.P., L.R.C.S. Ed., House Surgeon to the Bradford Infirmary.

WIGAN, C. A., M.R.C.S., Resident Obstetrical Officer to Charing Cross Hospital.

WILSON, A. H., M.R.C.S., Resident House Surgeon to the Liverpool Royal Infirmary.

Births.

CURGENVEN.—Dec. 1st, at 41 Friar Gate, Derby, the wife of William Grafton Curgenven, M.D., of a son.

Marriages.

BATCHELOR—HAWKINS.—Oct 12th, at Port Elizabeth, South Africa, Dr. George A. Batchelor, to Beatrice, eldest daughter of the late James Stillwell Hawkins, M.R.C.S., of Bow, London, and step-daughter of J. Robertson, M.D., Grove Hill, Woodford.

EATON—NOLAN.—Nov. 29th, at Donnybrook, Joseph Eaton, M.K.Q.C.P.I., L.R.C.S.I., &c., to Mary E. Gerrada, eldest daughter of William Nolan, Esq., of Simmonscourt, Donnybrook.

Deaths.

BRAD.—Nov. 22nd, at Laineswood, Burgess Hill, Sussex, after a few days' illness, James Brad, M.D. Edin., aged 60.

JENKINS.—Dec. 1st, at Newton, Plymouth, Sophie Pauline, wife of Dr. James Jenkins, C.B., R.N.

MYLES.—Nov. 23rd, at Parsonstown, at the residence of his brother, Dr. J. P. Myles, W. Zachary George Myles, L.R.C.P., L.R.C.S. Ed.

O'FARRELL.—Nov. 25th, at Taglier, Boyle, Co. Roscommon, Harvard O'Farrell, M.D., F.R.C.S., J.P., aged 71.

SMITH.—Nov. 30th, at Retford, Frederick Smith, M.R.C.S.E., L.S.A., late of 780 Old Kent Road, aged 43.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.
Surgeon to the London Hospital.

(Continued from page 478.)

THE idea of tolerance seems to have originated partly from the fact that post-mortem examinations of cases of ruptured bladder sometimes detect very slight, if any, traces of peritonitis, and partly from cases which appear to indicate the ability of the peritoneum to absorb urine effused into its cavity. The basis will not support the superstructure. For, if the history and progress of the cases in which pathological peritonitis was absent be examined, all the symptoms of intense irritation and inflammation of the peritoneum will be found, and the issue was death. The presence or absence of lymph as evidence of inflammation and irritation, or the contrary, is little to the purpose. Purulent collections, or serous exudation, may take the place of lymph. In Mr. Spence's case, on opening the abdomen, the large intestine was found contracted, the small intestines were rather more congested than naturally, but the peritoneum presented the usual smooth, glistening appearance. There was no marked vascularity, either of the parietal or visceral peritoneum; its surfaces seemed more bedewed with serous secretion than usual, although this did not amount to serous effusion. There were no adhesions, and only a very few minute flakes of lymph towards the epigastric region. Out of 30 intra-peritoneal ruptures, Dr. Stephen Smith notes that marks of inflammation were found in 27, and were absent in 3. Out of 60 cases in my list in which the post-mortem appearances are given clearly, the marks of peritonitis were strongly developed in 39, slight in 12, and absent in 9. Of the 9 cases, 1 was an insane patient, 4 died early—that is, within two or three days—I died in four and a-half days, another in five, 1 on the seventh day, and the other on the eighth day. Some allowance must certainly be made for errors in observation, for in one of the cases in which it is stated that there were no

signs of peritonitis a patch of lymph was seen over the bladder. Again, in the discussion at the Medico-Chirurgical Society of Edinburgh on Dr. Gillespie's case, one of the speakers described it as almost unique as regarded the absence of peritonitis; but if the account of the post-mortem examination be consulted, it will be seen that, though the coils of intestine were not glued together, there was plenty of turbid, flaky serum in the dependent portions of the peritoneal cavity, and there were numerous patches of bright vascularity on the visceral and omental layers of peritoneum. And here I may say, in passing, that I include under apparent errors in observation such statements as are made in the reports of two American cases concerning the *disappearance of the bladder*. In Dr. Kneeland's (a) case of extra-peritoneal rupture "no part of the bladder was found except the neck, to which adhered shreds of softened membrane in which a blood-vessel was observed, the ureters terminating in a pulpy mass in the pelvic cavity. Dr. Kneeland's patient died on the seventh day. Dr. Pendleton's (b) case is very extraordinary. A boy of 7, with his bladder distended, was trod upon, and was not considered injured till twenty-four hours afterwards. He died on the fourth day. Three gallons of fluid were found in the abdomen with pus in the pelvic cavity. There was *no appearance of the bladder*. Doubtless it was merely strongly contracted, lying concealed deep in the pelvis in front of the peritoneum; whilst in Dr. Kneeland's case, I imagine that the sloughy and infiltrated areolar tissue in the neighbourhood of the bladder was taken for the bladder itself, and that the so-called neck of the bladder was the actual bladder contracted. To support this view, I refer to a case of a man of thirty, who was under Mr. Spencer Wells, (c) He

(a) *New York Journ. of Med.*, March, 1851. This case gave rise to an action against the man who had injured the patient, and some curious evidence was given. Medical witnesses for the defence averred that a man with a ruptured bladder could not make water, and that two quarts of urine could not have been obtained at a time unless the patient had been tapped. With more truth it was urged that probably the bladder had not been found at all, that the bladder collapsed after death would not have been noticed *unless it was looked for*, and that if gangrened it would have been turned black, but would all remain in situ.

(b) *Charleston Med. Journ.*, vol. iv., quoted by Stephen Smith.

(c) *Lond. Med. Gaz.*, Aug.

fell from a hammock, and died on the sixth day. At the post-mortem it was seen that the tissues beneath the superficial fascia of the abdomen were dark-coloured and softened and gangrenous, exuding bloody serum with urinous odour. The cellular tissue round the bladder was in the same condition. The peritoneum was entire, but pushed upwards from the anterior surface of the rectum, and from the posterior and superior surfaces of the bladder, forming a large cavity with coagulated blood and urine, at the bottom of which cavity was the bladder, having a rent $1\frac{1}{2}$ in. long in the anterior wall. The edges of the rent were red and hard.

The majority of the cases in which there was only slight peritonitis died within three days, but Mr. Spence's case did not terminate till the fifth day, and Mr. Ellis's lasted fifteen days. Mr. Spence in commenting on this matter observes "when we recollect the amount of organic changes, such as extreme and general vascularity of the serous surface, the effusion of turbid serum and masses of lymph, and the matting together of the viscera, which usually follow the escape of even a small quantity of the contents of the intestines in cases of minute perforation, and where the fatal result generally occurs more rapidly, or in cases where a comparatively small quantity of urine is extravasated into the subperitoneal cellular tissue, it seems to me that the absence of such appearances in this and some other similar cases recorded, can only be accounted for on the supposition that the extremely destructive character of the extravasated urine in large quantity, and in immediate contact with the peritoneal surface, may so depress the vital powers as to prevent the formation of the ordinary inflammatory products, a condition, however, somewhat difficult to reconcile with the acute nature of the symptoms during life, and the period intervening between the receipt of the injury and its fatal termination." Evidently the tolerance of urine by the peritoneum must be judged not merely by the effusion of lymph, but by the local and general symptoms and by the issue of the case. If the intrusion of urine into the peritoneum produces intense pain, tenderness, and distension of the abdomen, and if these symptoms are accompanied by constant vomiting, restlessness, a sunken anxious countenance, altered temperature, feeble pulse, hurried respiration, clammy sweats, and intense prostration terminating in death, I cannot understand why it should be affirmed that the peritoneum tolerates the presence of urine, because after death it is found to have retained its smooth glistening aspect, and to be free from undue vascularity, adhesions, and lymph. That the peritoneum may absorb urine poured into its cavity I will not dispute. Careful examination of the post-mortem records induces me to think that absorption, if any, must be slight. The absence of any considerable quantity of urine in some of the cases is explained by the withdrawal of the fluid by catheterism of the peritoneum through the rent in the bladder, in others by its diffusion through the peritoneal cavity so that its actual quantity was insufficiently estimated. Many cases show abundance of urine in the cavity for the length of survival. To quote only one instance.

In Mr. Ellis's second case, which terminated on the fifteenth day, two or three gallons of pale urinous fluid were found in the abdomen, allowing for the accumulation of a pint and a-half a day in addition to the amount drawn off with the catheter. But even if urine be absorbed by the peritoneum in any quantity as conjectured by Solly, Le Gros Clerk, Max Bartels, and others, I entertain very little doubt that such absorption must exercise a most depressing influence upon the system of the patient in whom the absorption occurs. This is not denied even by some of the advocates of tolerance. Thus, his lectures "On the Surgical Disorders of the Urinary Organs" (p. 318.)

Mr. Reginald Harrison observes: "There is good reason for believing that the peritoneal cavity is more tolerant of the presence of healthy urine than at first we might be inclined to suppose. In fact, I would go further

and say that, in these cases the fatal peritonitis set up is not due so much to the entrance of healthy urine within the limits of an uninjured peritoneum, as to the decomposition of urine which follows its confinement by, or even contact with, tissues more or less disintegrated by violence. Menzel's experiments (*Wien Med. Wochenschrift*, Nos. 81-85, 1869) are confirmatory of this view, as they demonstrate that healthy urine does not in itself cause destruction, and that its effects on the tissues are innocuous, so long as an escape is provided for it." Mr. Harrison then adduces Mr. Crossley's case, already quoted, as one in which the patient was almost within the limits of recovery, and observes that the patient "was poisoned by his own urea before nature had time to provide some compensating action by which it could have been got rid of. Such instances seem to show that if no extensive damage is done to the structures of the abdomen, if the urine that finds its way into the cavity of the peritoneum is not largely contaminated with blood, or other source of putrefaction; and if escape, as by catheterism, is provided for urine so effused, serious peritonitis is not necessarily provoked. In the majority of cases of intra-peritoneal rupture of the bladder one or other or all of these conditions are usually absent. The urine, under such circumstances, largely mixed with blood decomposes and gives rise to that rapid and destructive inflammation which, in spite of all treatment, brings these cases to a fatal termination in the course of a few days." In short, the subject of an intra-peritoneal rupture of the urinary bladder is placed between two fires—either he falls a victim to an intense peritonitis, or he succumbs to urinary intoxication—and the idea of tolerance disappears, for however tolerant the peritoneum may occasionally appear, intolerance is plainly exhibited by the system of the patient. Nor is urine tolerated by the areolar tissue, be it the urine of the infant or the urine of the adult. Both alike when penned up in the meshes of the tissue will set up intense inflammation, suppuration, and sloughing, and I distrust altogether any statement which would involve any opposite conclusion. I must not, however, pass over an important and interesting observation made by the author just quoted, concerning the innocuous character of urine deficient in its organic solids. Mr. Harrison says: "As bearing upon what has been said about the decomposition of urea as a cause of alkaline urine, I may mention a case which I saw some little time ago which much interested me. It was one of stricture, with extravasation of urine into the scrotum, occurring in a person suffering from Bright's disease of the kidneys. Though the extravasation had come on suddenly, and had existed for twenty-four hours unrelieved, there were no signs of acute inflammatory action and commencing gangrene, such as are usually expected. However, the tension being considerable, I incised the parts involved in the extravasation. As the fluid escaped from the incisions, I noticed that it had not that strong ammoniacal odour which is so perceptible in such cases. Subsequently I treated the stricture, which was exceedingly tight, and for some time kept in abeyance the more threatening urinary symptoms. I was somewhat puzzled for an explanation, as I felt sure that the case was one of extravasation, and not of acute scrotal oedema. How was it, then, that extravasated urine failed to create gangrene? I collected some of the urine as it trickled through the wound, and compared it with some subsequently drawn off by the catheter. I found them identical, and in both there was almost a complete absence of urea. This, then, to my mind, solved the mystery, and explained that as there was no urea to decompose, there was no source for the production of the ammonia by which the destruction of tissues in connection with extravasated normal urine is effected. By the absence of urea the urine was rendered chemically harmless to the tissues with which it came in contact."—*Op. cit.*, p. 51.

At the Galway sessions, a man, named John Hanlon, was sent to gaol for a month, for writing a threatening letter to Dr. Nally, of Kinyarra.

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

(Continued from page 480.)

III.—On the Seat and Mode of Origin of the Disease.

PATIENTS with hip disease seldom die during its early stage; hence post-mortem evidence of the primary changes is rare. We find, therefore, that, through the absence of positive proof upon the point, much speculation has arisen as to the mode of origin of the disease. Every structure in the joint has in turn been mentioned as the seat of origin. Even the synovia has not escaped. Thus, an old writer, Freake, (a) considers the disease to be due to "an acrimonious condition" of this fluid, capable of producing caries of the bone. Synovia, he says, is like "good olive oil for locks," but, adds he, "if oil of vitriol be used instead of it, the effect need not be told." De Haen's (b) view of the seat of the affection is sufficiently comprehensive. He says it may exist "in the integuments, in the cellular membrane, the membrane fascia, the muscles, the involucre of the ischiatic nerve, the periosteum of the bone, the capsular ligament, the cartilages, the bone itself, the glandular innominata, the ligamentum teres, or finally in all the above mentioned parts together." Ford (c) considered that the disease arose in a "morbid state of the cartilages and bones;" Astley Cooper (d) and Coulson (e) that it commenced in the synovial membrane; Albers (f) and Rust (g) that it commenced in the head of the femur; Brodie (h) considered ulceration of the articular cartilages the primary affection; Bell (i) that it commenced in the Haversian gland; Key (j) that it started in the ligamentum teres; Syme (k) that it arose as a chronic inflammation of the bones. Among modern authorities, Hilton (l) considered that, "on the whole, the disease commences more frequently in the ligamentum teres, than in any other portion of the articulation;" Holmes (m) thinks that in many cases the disease begins by inflammation of the ligaments; Barwell (n) thinks there is no doubt that it may begin in the synovial membrane or bone, but not in the ligaments or cartilages; Pirrie (o) that in young children, the disease begins in the cancellous tissue of bone, but that in patients past puberty, cartilage is the primary seat; Erichsen (p) considers that any one of the structures, hard or soft, forming the joint, may be the starting point; Annandale (q) that the head of the femur is most frequently the seat; Druitt (r) that it may begin as inflammation of either bone or synovial membrane; Macnamara (s) that "it may commence in the medulla contained in the head or neck of the femur or of the acetabulum, it may begin in the synovial membrane of the joint, and before puberty in the soft structures situated between the epiphyses and diaphyses of the upper extremities of the femur, as well as in the epiphyses of the acetabulum;" Sayre (t) thinks that it may begin in one of three ways: firstly, as a synovitis, secondly, in rupture of the round ligament, and thirdly, in rupture of minute blood vessels beneath the articular cartilages; Croft (u) believes it begins as tubercle in either bone or synovial membrane; Gant (v) that it commences in the cancellous tissue of the head of the femur or of the acetabulum, probably in both bones simultaneously, this writer also believes that it may begin in the synovial membrane in scrofulous subjects; Bryant (w) that it arises generally as "an inflammatory action of the bone" extending to the joint; lastly, Virgil Gibney, (x) a recent American writer, thinks that it always begins as a central disease of bone.

Having reproduced the above views, as seems only due to the distinguished surgeons who have held them, I would venture to express the opinion as to the seat of hip-joint disease that I have been led to form after considerable study of the opinions of others, of clinical evidence, and of post-mortem appearances. I would urge strongly, that in the great majority of cases, the disease begins as a *simple catarrhal inflammation of the synovial membrane*. Cases beginning in this way I would designate "Cases of Ordinary Origin." A small proportion of cases, however, appear to

begin in one or other of the many ways mentioned above, and these, being comparatively few, I would call "Cases of Extraordinary Origin." A few remarks will be offered upon each class of cases.

1. *Cases of Ordinary Origin.*—In these, as just stated, the disease begins as a simple inflammation, acute or sub-acute of the synovial capsule; the process commencing as active hyperæmia, passing on to exudation into the joint and beneath the epithelium, and ending, if left unchecked, in destruction of the synovial membrane by cutting off its nourishment from beneath. This simple synovitis is probably exactly similar to that which affects the knee-joint after a sprain, the pleura after a chill, or the peritoneum after a wound, and may be caused by the slightest traumatic causes in an individual of weak constitution.

In support of this view of the origin of the disease, both clinical and post-mortem evidence may be offered. Thus, it will be remembered, that one of the earliest clinical signs of the affection is a fulness about the groin, due apparently to distension of the joint by fluid. Prior to this, there is a desire to keep the joint stiff, and the local pain produced by moving the joint is to be accounted for by the friction of the congested and thickened synovial membrane. The pain in the knee, always an early symptom, I believe to be caused by the pressure upon the obturator nerve of the capsule distended by fluid (not to reflex action), for in the case of a synovial membrane exudation follows congestion in quick succession. Further, it will be remembered that the psoas and iliacus muscles pass closely over the capsule to the place of insertion, and when tense they would exercise considerable pressure upon the joint. Hence we find, that quite early in a case the patient keeps his leg flexed and adducted, in this way relaxing these muscles and removing pressure from the joint. Now, it appears difficult to understand that these symptoms should be produced if the seat of the disease were either the acetabulum, the head of the femur, or the cartilage encrusting either bone, for no motion of the joint or alteration in position of the limb would affect these. And if the ligaments were inflamed, a posture which would relax some would render tense others, and pain would not be diminished. With regard to the round ligament, Mr. Key, who considered that the disease commenced in that structure, founded his opinion, not so much upon observed facts as upon the old view that the round ligament checks abduction, a view which is now known to be erroneous.

The post-mortem evidence of the earliest stage, little as this at present is, I would venture to claim as supporting the view I hold. Coulson, in the case of an infant upon whom he made a post-mortem examination, when the disease had existed only two months, found "the round ligament destroyed, and the synovial membrane inflamed, there was absorption of some portion of the cartilage covering the head of the femur, and of the cartilaginous rim of the acetabulum; but, on making a section of the femur the bone was found healthy, and the cartilage no further destroyed." Holmes refers to a case which he examined after death in an early stage, and in which, "little more was to be seen beyond an inflammatory condition of the synovial membrane." In a specimen of a similar case at the Children's Hospital, which Dr. Abercrombie was so good as to show me, there had been distension of the joint with fluid, and the synovial membrane was found congested, especially that covering the ligamentum teres (that is, where there is most room for expansion of vessels). The disease in this case had existed for three weeks only. In another case, mentioned by Holmes, and examined a month after its origin, a quantity of lymph was found in the joint, and some ulceration of the round ligament; and the same author mentions a French case, in which death occurred in a few days from acute abscess, and in which the chief, if not the sole morbid appearance, was an inflammatory state of the synovial membrane, with ulceration of the ligamentum teres (an explanation of ulceration of the round ligament will be given later). Sir B. Brodie records a case in which death occurred a

week after a wrench of the hip-joint. The synovial membrane, in this case, was found ulcerated, and the joint contained about an ounce of dark blood. In the museum of St. George's Hospital is a specimen (y) from a case of ten weeks' duration. Here, not only has the synovial membrane disappeared, but the cartilage also, in parts where the disease has more advanced; showing that the process originated upon the joint surface. A most interesting and detailed account of a case, with post-mortem appearances, both naked-eye and microscopic, is recorded by Dr. Willard and Shakespeare. (z) The account is too long to be reproduced here, but it may be stated briefly that the observers came to the conclusion that the stage was the "first or initial" stage, and that the intensity of the morbid process affected mainly the synovial membrane.

The above cases, in which post-mortem examination has been made comparatively early, have not been selected, but are all of the kind which have come under my observation, and I would point out that in not one of them is there evidence that the disease commenced in either bone, cartilage, or ligament, but that all show, as I believe, the common origin of the affection in an inflammation of the synovial membrane.

(To be continued.)

TREATMENT OF NEURALGIA. (a)

By CHARLES R. FRANCIS, M.B. Lond., &c., &c.,
Formerly Professor of Medicine in the Medical College, Calcutta.

(Concluded from page 482.)

WITH regard to the various ante-neuralgic remedies in general use, their efficacy consists for the most part in diminishing, or altogether removing, the pain for the time. They are essentially pain-killers. Many of them are simply local applications—as, ointments of atropia, aconite, or veratris; oil of peppermint; a combination of iodoform and chloroform; chloroform alone; chloral and camphor; liniment of belladonna; a strong infusion of capsicum on lint, covered over with gutta-percha; ether spray; hydrocyanic acid and cyanide of potassium; oleate of morphia, &c. Sometimes the benefit of the remedy—taken internally—is limited to certain nerves, as chloride of ammonium, valerianate of zinc, chlorate of potash, croton chloral, &c., in facial neuralgia; gelseminum, chamomile, nitrite of amyl (inhalation), for neuralgia of the fifth pair; carbonic acid injection for neuralgia of the uterus. Then, various remedies are employed to diminish the sensibility of the nervous system generally—as bromide of potassium, cannabis indica, conium, stramonium inhalation, the spinal ice-bag, &c., &c.; or to give that to the nervous system which is supposed to be deficient—viz., phosphorus; or to stimulate it—as tea, coffee, guarana; or to supply some deficiency in the blood—as iron in anæmia. Other remedies are prescribed to give tone to the nervous system and improve the general health—as electricity and galvanism, quinine, and arsenic; the two last, in cases of well-marked periodicity, being given in larger doses to anticipate an attack. Counter-irritation, in the form

of flying blisters, has been recommended for the shifting neuralgic pains common in nervous sensitive women; but, as the pain is pretty sure to go elsewhere, and much cutaneous tenderness is often left, their value is doubtful. Flying blisters, in my own experience, are most beneficial where there is effusion between a nerve and its sheath, or thickening of the latter. I have found them of excellent service in the latter condition in sciatica, applied above, and in the course of, the seat of pain. They are also decidedly useful in intercostal neuralgia after shingles.

All these various remedies (and indeed in some instances nothing more is required—I refer particularly to those that are merely pain-killers) are of more or less value so far as they go; but, for the permanent cure of neuralgia something more, generally speaking, is required. As before observed, all cases cannot, as a rule, be treated exactly alike. To begin with (this is a rule of almost universal application) I recommend total abstinence from alcoholic drinks whether as beverages or medicine—as medicine, I mean, for the neuralgia. Let the neuralgic sufferer substitute Kepler's malt extract, or maltine, for his beer or stout, or even take no substitute, and he will be surprised at the result. It may be that, without anything further, the attacks of pain will altogether cease. If medicine be required I strongly recommend the union of a nervine tonic and an anodyne, administered on a systematic principle, and to serve as a fortifier and tranquillizer of the weakened and irritable nervous system; and, when necessary, in still larger doses as an anti-periodic. In malarious fevers, by adding an opiate to the tonic (quinine), an earlier and more complete cure is ensured. Less quinine, too, when that is given, is needed; and there is, consequently, less probability of tinnitus. So, in periodic neuralgia similar results may be expected. Dr. B. W. Richardson has, in vol. xii. of the *Medical Temperance Journal*, pointed out the advantage of the combination, which is becoming generally recognised.

It is by no means necessary in all cases to give heroic doses of the anti-periodic; though, in those of a chronic nature, it will usually be necessary. Quinine, where admissible, is undoubtedly the best; but, when it cannot be borne, sulphate of cinchonine in similar doses answers almost as well. Salicine may be given in gr. x. doses, repeated at intervals of half-an-hour, up to gr. xxx. Neither of these drugs causes tinnitus when given, even in anti-periodic doses; unless, indeed, these be very large or frequently repeated. Where quinine can only be borne in moderate doses, it and arsenic go very well together; gr. v. of the former, and ℥i. of Fowler's solution; or, ℥xx. of this solution alone will suffice. Though, from ample experience with this drug, I should not hesitate to prescribe even so much as ℥xxx., and repeat it in a short time—say an hour—if absolutely necessary, I think it is preferable to use other anti-periodics in the first instance. Whenever arsenic is used an anodyne should, of course, be combined with it, to counteract its irritating action on the stomach and intestines. It is well to bear in mind that quinine may often be tolerated hypodermically, when the stomach will not bear it: and that gr. v., thus introduced, is equal in efficacy to gr. xxx. swallowed. The neutral sulphate should be used. It is readily soluble (gr. j. to ℥xij.) in water without the aid of any acid—a great advantage, as there is then less fear of irritation of the skin, and boils. It is not uncommon for a patient to say, on hearing that quinine is to be given, "Oh! I've taken lots of quinine." Yes, but how! One frequently finds it prescribed in small doses as a general tonic, but rarely, except, of course, in well defined malarious cases with periodicity, as an anti-periodic. Neuralgic patients often require a deal of looking after. And herein lies the advantage which the practitioner, who sees his patient almost daily, enjoys over the physician who perhaps has only seen him once.

(a) Read before the Harveian Society of London, Nov. 10th, 1892.

The nature of the tonics is a point for consideration. Easton's syrup, as containing quinine, iron, strychnine, and phosphorus, is the best where the several ingredients can be borne. But, whatever be selected, I must repeat my recommendation that an anodyne be combined with it, care being taken to counteract any functional irregularities that may be caused by its exhibition. And of anodynes I would advocate nepenthe, a preparation of opium manufactured by Messrs. Ferris and Co., of Bristol, which deranges the functions, if at all, less than any other—resembling in this respect the bi-meconate of morphia. Hyoscyamus may be substituted in the case of those who cannot bear opium in any shape; or conium, or belladonna, or croton chloral. This last is very promising. Belladonna, which we find in India to be so serviceable in alleviating the neuralgic pains of dengue, might be more extensively used.

Of surgical remedies, as nerve tapping, stretching, and the like, I have no personal experience. One can readily understand that the victim of neuralgia in its most agonising forms—e.g., tic douloureux—would readily hail any measure that gave promise of relief, even excision of a ganglion. There are not cases enough of this operation, or of nerve stretching, on record from which to form an opinion as to the efficacy of either; but, inasmuch as sensations—pain, even—have been felt in the distal ends of an extremity after removal of the limb, I should question the permanent value of the former; and, notwithstanding the recorded efficacy of the latter, I should be too afraid of tetanus (a result which has indeed occurred) to submit to it myself. It seems, moreover, so directly opposed to that most valuable of all remedies, and from which the nervous system would specially derive advantage—viz., rest. I once had a patient who declared that he constantly had neuralgia—and very severely, too—in his hair! Such a case would surely be beyond the reach of surgical interference!

Amongst the most troublesome of the so-called neuralgic cases that come before us are those where neuralgia seems to be blended with myalgia. I am acquainted with a lady who declares that she has a cancer growing in her right side—the exact spot being about the centre of the infra spinatus muscle. The pain, which is always referred to the same spot, is not constant; indeed, she is sometimes without it for several days. It is unaffected by pressure, and unaccompanied by swelling; nor is there any sign whatever of malignant disease. Playing the piano brings on the pain after a time. Nothing can persuade this lady, who is of a highly nervous temperament, and who has suffered severely from neuralgia, that she is not the victim of malignant disease. Within four years she has consulted three physicians, three surgeons, and nine general practitioners—fifteen in all. The late Charles Murchison, and Hilton, Paget, and various others have all coincided in opinion that, upon a very slender basis of truth, there is a huge superstructure of fancy. She is now 40, and, although it is evident that the disorder makes no progress—the lady has lived in dread of an open cancer,—this patient will have it that the cancer is there, and that the doctors are all wrong. In some of these cases there is a rheumatic basis, as in the omodynia, scapulodynia, and dorsodynia, observed amongst labouring men; in others there may, at some previous period, have been slight rupture of muscular fibres; in others there may be a neuralgic origin; in all, more or less defective innervation, so that the particular muscle affected is easily fatigued—pain even being sometimes induced—on exertion. Each class of cases must, of course, be treated in part according to its original nature. A mixed soothing and stimulating plan will usually be attended with most success; but, speaking generally, many cases of this description are, I venture to think, well suited for treatment by massage. To the limited extent of shampooing, or muscular kneading, practitioners in India are familiar enough

with massage. No one who has not experienced it can appreciate the effect induced, where the tired muscles of the legs are kneaded by the hands of an expert after a day's shooting, or other hard work. Fatigue is no longer felt to the extent of preventing sleep, but, in its place, a sensation of pleasurable weariness that cannot be described; nay, sometimes, the weariness disappears altogether as if by magic.

It may be sound and very common-sense advice to give to a lady patient, who complains that when she crochets she has pain in one particular spot in her side,—"Don't crochet." But something more would be expected from a physician; and I believe that in massage we possess an excellent remedy that is well suited to these cases, where the uneasiness—it often hardly amounts to pain—constantly returns in the same spot, until at last the mind is not unnaturally led to imagine the worst. In addition to the general treatment suited to the particular case, whatever amuses the mind and, lifting it as it were out of itself, diverts it into other channels, must have a beneficial effect.

Neuralgia is often regarded as hopelessly incurable. And so, at one time, was the "collapse" condition in cholera; whereas, now, fifty per cent., under appropriate treatment and if the patient have a good constitution, recover. I would, therefore, urge upon my professional brethren, when treating the most unpromising case of neuralgia as when endeavouring to maintain life in the most advanced stage of that fell disorder, the adoption of the motto "*Perseverando*."

THE ESTABLISHMENT AND MAINTENANCE OF BRAIN HEALTH. (a)

By J. BATTY TUKE, M.D., F.R.C.P., F.R.S.E.,

Formerly Morrisonian Lecturer on Insanity, Royal College of Physicians, and Lecturer on Mental Diseases, Royal College of Surgeons, Edinburgh.

DR. TUKE said he held it to be a well-ascertained physiological fact that the brain cells were organs which could be acted on for good or for evil, and that they were directly subject to the laws of health. It might be said in passing that, as a nation, we had decided to adopt a system of education which was in itself the greatest brain tonic at our command, a remedy which, if not altogether a specific, must strike deeply at one great cause of crime, misery, and degradation. Especially in our great cities there was a considerable class the members of which might be termed moral idiots. A child brought up, or rather dragged up, in a cellar, whose parents were thieves by profession; whose companions were equally degraded; who was surrounded from his earliest days by scenes of debauchery and wickedness, must almost inevitably fail to develop a moral sense. Right was wrong to him, and wrong was right. Strictly speaking, this was his moral sense. Some of them might feel at times inclined to grumble at the expense and working of the Education Act; but the grumble would cease if they reflected that they, as a nation, were doing their very best to remove a serious opprobrium from society. The Compulsory Education Act was something like the Compulsory Vaccination Act. Society had determined, in the one case, to apply a preventive to the spread of a serious and dangerous bodily disease; and, in the latter, to a grave and serious moral disease. In speaking of the influences which act for good or evil on the brain, Dr. Tuke alluded first to those over which the individual had no control; and, second, to those over which every man and woman could exercise control. The influences over which the individual had no control were those connected with his antecedents and up-bringing. A man might be handicapped in life by the mistakes or faults of his ancestors; and, different from the racehorse, he had to carry weight in the race

(a) Abstract of Lecture delivered before the Edinburgh Health Society, Dec. 2nd, 1882.

of life according to his imperfections, not according to his advantages. There was a pretty general consensus of opinion that consanguineous marriages were on the whole to be deprecated. If they tasked their memories, and tried to remember how many perfectly healthy families they had known—families without a history of consumption, gout, rheumatism, affections of the nervous system, &c.—he feared the number they could estimate would be very small; and if they took into account the tendency of such diseases to become intensified in the children of cousins, he thought they would agree with him that consanguineous marriages involved a risk which it was not well to incur. Alluding next to a question which was often put him by anxious parents, whether it was advisable to allow their children to marry into families in which nervous disease was known to exist, he remarked that, of course, as an abstract proposition, there was but one answer to the question—that it was not advisable; but while he did not advocate marriage under such conditions, he expressed the opinion that there was not much more, if any, reason for avoiding a family in which there was a history of nervous instability than there was for avoiding families in which other forms of hereditary disease existed. Passing to consider the practical questions connected with the rearing of the infant and child, he said every child's future history depended on the food it got and on its surroundings. Much depended on the mother; if healthy, she should suckle her child, but not for too long. He had met with many cases in which the sole ascertainable cause of nervous symptoms in young children was their being too long suckled. But the mother herself must be well fed, and this brought him to the consideration of another question.

In some respects he believed the food of the working classes in Scotland was improved, partly because wages were higher, partly because in the new workmen's houses the means of cooking were better, and partly because new articles of diet had been introduced into the market. But he also believed that it had become deteriorated in a very important item—porridge and milk—for which had been substituted a much less nutritious, and in itself a somewhat deleterious article of diet—tea and bread. The physiologist would tell them that porridge and milk was a "typical" food—that was, that it contained all the necessary constituents of food in the most perfect proportions. He had nothing to say against the staff of life so long as it was sound in quality and well fired, except that it was not such a typical food stuff as oatmeal, and, weight for weight, did not possess as equal power of nutrition as porridge. He advised all working men, whether they worked in the workshop, in the office, or in the study, to feed themselves, their wives, and their children, at least once a day on the most perfect form of food which God had given them—porridge and milk. The next subject which naturally suggested itself as exercising an important influence on the child's brain cells was education.

With every respect for the management of public philanthropic institutions, he would much rather see a child of his less well dressed, less well fed, living early into real life, his brain cells absorbing real experience, and becoming educated by normal vicissitudes than see him the best boy in the best hospital in the country; and, speaking as a physician and a physiologist, he would advise all to avoid the temptation, should it be presented to them, of sending their children to any institution when, by any sacrifice, they could keep them at home. Of course, a child had to encounter greater dangers at home than when shut up in a monastic institution. They were overworked, and overworked themselves, at school. One of the great causes of overstrain in early youth was the vicious system of offering prizes for competition. It deflected the mind of the child from the main aim and object of its study, and often defeated the object which it was hoped to obtain. The youthful mind must not be pressed too far in the direction of

abstract facts and theories. Our own educational system was running somewhat wild in this direction, and the child's brain did not get time to assimilate the food it got. A sort of brain dyspepsia or indigestion set in.

His experience might be exceptional, but it tended towards the opinion that the rising generation was not so well acquainted with the standard literature of our own country as boys and girls were twenty-five or thirty years ago. He dared say its knowledge of the hard facts of history was more exact, the rules of arithmetic might be more thoroughly understood, but he doubted very much whether "Robinson Crusoe," the poems of Burns, the "Pilgrim's Progress," Sir Walter Scott's glorious novels in prose and verse, Prescott's "Conquest of Mexico and Peru," and such like educational influences were as much at work as they used to be. Careful reading of such standard books helped the boy's and girl's brain to assimilate the tougher food it received at school, and introduced a digestive power which helped to diffuse the aliment throughout the whole mental system. Having pointed out the necessity of teachers knowing how to administer intellectual aliment carefully and thoughtfully, and how brain health suffered now-a-days, if there was truth in the statement that the pupil was being made for the school, not the school for the pupil, Dr. Tukey remarked that a great deal had been said and written of late about the overworking of girls and young women in schools and colleges, and his friend Dr. Clouston had come forward as the champion of health and ignorance for women. He could not help thinking that Dr. Clouston had overstated the position of matters; that he had based his opinions more on the observation of isolated cases than on the general condition of highly-educated women; that he had mistaken the wail of the one for the murmur of the many. No doubt a certain number of young women suffered and broke down whilst studying, but this did not necessarily imply that study was the cause of the breakdown. Idleness and ignorance were much more prolific causes of disease amongst women than overwork. They were the main producers of hysteria, and all sorts of vapourish complaints, of many ills and evils, and of insanity, if not of insanity. As a matter of fact, it was not an easy thing to overtask the energies of the brain by work. It was not work, but worry that killed the brain. The latter, he feared, must be ever with us all. The most highly-educated and hard working women whom he had the honour of knowing were eminently healthy. Perhaps this might be the "survival of the fittest;" but even granting that it was so, the more women worked, the more fit women they would have. But breakdown from overstrain did occasionally take place, and the first really important symptom was sleeplessness; when that set in there was cause for alarm. Loss of sleep was brought about thus:—When the brain was being actively exercised, there was an increase of blood in its vessels—this was spoken of as "functional hyperæmia." If they continued the exercise of the brain powers too long, there was a tendency for the blood to remain in too great quantity from the cells becoming exhausted and not being able to control the vessels. In sleep the amount of blood was diminished, and sleep could not be procured if this functional hyperæmia persisted. In the absence of sleep, the cells could not recover themselves, and their activity became impaired. Headache, loss of appetite, and general listlessness followed; then changes in the character of the blood, and the trains of symptoms so ably described by Dr. Clouston. As soon as a child or young person developed continuous headache, work should be discontinued at once. In conclusion, Dr. Tukey remarked that most men working in the same department of medicine as he did recognised that if there was a hope of diminishing the amount of brain disease, it was to be effected by preventive medicine, and he had therefore directed their attention more especially to the transgressions of the father than to those of the son.

Clinical Records.

ST. MARY'S HOSPITAL.

Chronic Destructive Arthritis of Knee-Joint—Excision—Temperature normal throughout after the seventh day—Cure.

Under the care of Mr. NORTON.

THE subject, a boy, *æt.* 4, whose history could not be obtained, was admitted on the 24th February, 1882. At the date of admission the left knee-joint was considerably enlarged, the ends of the bones femur and tibia being increased in size, and the synovial membrane thickened and protruding as a pulpy mass on each side of the patella; the leg was bent at almost a right angle with the thigh, and could not be straightened, any attempt at so doing being accompanied by severe pain. About two inches above the knee on each side of the thigh was an abscess, fluctuating, but not yet discharging. The abscesses were opened, and then poulticed, but, as the poultices soon brought about an eczema, they were replaced by vaseline applications. An attempt was made to straighten the limb somewhat by means of a McIntyre splint whilst the patient was under chloroform but so much pain resulted, and the child cried so incessantly, that it was removed on the following day, and a light weight and pulley ordered to be applied to the foot.

Little or no change took place in the state of the patient. He took his food well, and temperature was normal throughout, and on the 29th March the abscesses were still discharging, but a probe would not pass into the joint. The symptoms of disease of the joint were masked, for the child was apparently in good health and spirits, and suffered from no symptomatic fever or constitutional symptoms. Yet it was evident that the joint was somewhat extensively diseased from the pain produced when any attempt was made to straighten the limb, from the enlargement of the entire joint, and especially of the prominence of the pulpy synovial membrane on each side of the patella.

On the 19th of April it was decided to resect the joint. A curved incision was made below the patella and that bone turned upwards and the joint exposed; the ligaments were cut through and the ends of all the bones made to protrude; sequestra were found in both the femur and tibia, and the diseased portion of both bones was sawn off; bleeding, which was rather profuse, owing to the dilatation of vessels from the long-continued chronic inflammation, was arrested by ice. The bones were now approximated, a drainage tube inserted on each side, and the limb fixed upon a back splint. Listerian principles were strictly carried out throughout the operation and after treatment. Two minims of liq. opii sed. were given in a teaspoonful of water every hour till the patient went to sleep; and he passed a quiet night. On the 20th April the limb was dressed antiseptically, and the wound syringed through to wash out any clot of blood, the temperature of patient being at the time 102.6°. The traumatic fever remained at about 102° till the third day, when the temperature dropped to normal, though it rose again in the evening to 101°. After this the temperature lowered gradually till the seventh day after the operation, when it became normal and remained so during the rest of the convalescence of the child. The child's pulse was quick, often 140 per minute, though I think nervousness had a great deal to do with the rapidity of pulse; yet taken when the patient was asleep, it was still 110 per minute. The dressings were changed every two days for a time, and after the first week only once in three days, then once only in the week.

The splints were not removed till June 12th, after which patient was allowed to crawl about the ward. He was discharged on July 20th, considered to be cured.

Seen on December 8th, that is, more than nine months after the operation, the bones were well fixed, in a perfectly healthy condition, and the limb was about an inch and a-half shorter than the sound limb. The child walks about, looks healthy, and is in good condition.

FRIDAY, DECEMBER 8TH, 1882.

The President, Professor LISTER, F.R.S., in the chair.

Mr. RICKMAN J. GODLEE on

THREE CASES OF INTUSSUSCEPTION IN INFANTS TREATED BY ABDOMINAL SECTION.

Case I., *æt.* 9 months, was admitted into University College Hospital with well-marked symptoms of intussusception, from which it had been suffering for four days. The bowel protruded at the anus. The child was very ill and weak, and it was doubted whether it was justifiable to perform any operation. It was not thought wise to spend much time on attempts at inflation, and accordingly abdominal section was performed without much delay. Antiseptic precautions were adopted throughout; the child being as far as possible protected from the chilling influence of the spray by using as small a volume as possible, and wrapping up the greater part of the trunk and legs in cotton wool. No great difficulty was experienced in finding the point of involution, nor in reducing the intussuscepted part; the wound was secured as in an ovariotomy, and a dressing of iodoform wool was applied and secured by a flannel roller. The temperature rose the day after the operation to 105, but soon fell to about 100. It was necessary to give small quantities of brandy after the operation, and for some few days minim doses of laudanum were given to check restlessness and a slight diarrhoea which ensued. A little suppuration occurred along the course of the sutures, but the wound healed well, and by the eleventh day it had completely closed, the child being apparently in perfect health.

Case II. was a somewhat younger child who had been seized with sudden pain two days previously. The symptoms of intussusception were clear, and a sausage-shaped tumour was felt to the right of the umbilicus easily movable, especially from above down. In the intervals between the spasms, the child was apparently free from pain. Under the influence of chloroform, the tumour could be easily felt, and it was thought that it diminished under manipulation, but as a considerable mass remained, the abdominal section was performed as in the previous case, and reduction was effected by grasping the end of the ileum and drawing it toward the wound. Next morning the child seemed pretty well, but peritonitis set in rapidly, and death occurred the following night. The spray used in this case was remarkably small. At the autopsy the last two inches of the ileum and the first two of the cæcum were found much congested and thickened, and some slight ulceration had occurred in the ileum; the rest of the intestines were almost empty. There were marked appearances of peritonitis.

Case III.—A child, *æt.* 14 weeks, was admitted into the North Eastern Hospital for Children, with symptoms of intussusception that had lasted several days. The child was very ill, and the abdomen much distended and tender. The bowels protruded at the anus. Abdominal section was performed. It was very difficult to find the point of involution, which was seated deeply in the splenic region and correspondingly difficult to effect the reduction. After about four inches had been drawn out the cæcum and vermiform appendix appeared, and thinking that the reduction was complete, Mr. Godlee drew the cæcum towards the iliac fossa and closed the wound in the abdominal wall. The child never rallied, but died eight hours after the operation. At the autopsy it was found that seven inches of large intestine still remained unreduced. It was clear that the involution had commenced, not as is usually the case, at the ileo-cæcal valve, but at some point in the course of the transverse or perhaps the ascending colon. Some sloughing had already occurred in the cæcum. Mr. Godlee pointed out how easily such a mistake as that which he made in the last case may occur, and the manner in which it may be avoided. He did not feel discouraged by the result of the last two cases, but, whenever the gut protruded at the anus, he would at once proceed to the operation, or at all events would not waste much time in attempting inflation. On the other hand, in cases such as the second recorded he would give inflation and injection a good trial, since those are the cases most likely to be cured by this proceeding, and they are in a condition better able to bear the exhausting results which it causes; and moreover, it is clear that the danger of peritonitis is a real one, even if the operation be carried out antiseptically.

THE proceeds this year of the Hospital Saturday and Sunday collections in Manchester amount to £7,537, being an aggregate increase of £1,585 over the sum raised in 1881.

Mr. GEORGE BROWN ON A

CASE OF ACUTE INTUSSUSCEPTION.

The patient, a little boy, aged two years and nine months, an active and robust little fellow, was taken suddenly ill about an hour after a hearty breakfast, on the morning of Friday, April 14, 1882, with severe abdominal pains, followed by sickness and constant desire to go to stool. His bowels had acted naturally in the morning, and up to the sudden attack he was apparently in excellent health. Mr. Brown saw the patient within an hour of the onset of the symptoms, and found him on the sofa crying and writhing in agony. Ordered hot fomentations to abdomen and two-minim doses of liq. opii sed. every hour. The symptoms, however, continued very severe the whole day, and towards night blood mixed with mucus was voided from the bowels in considerable quantity. This pointed almost conclusively to the nature of the case, and the diagnosis was confirmed on the following morning, by which time the invaginated intestine could be felt in the rectum. The abdomen was much distended, and there was a large sausage-shaped tumour in the left inguinal and lumbar regions. The case being one of extreme gravity, Mr. Brown suggested the calling in of a consultant, and Dr. Cholmeley saw the patient on the 15th, who recommended enemata and insufflation, with the internal administration every hour of a full dose of henbane, to be tried before resorting to an operation. The henbane, after a few doses, had a very soothing effect, but the enemata and insufflation only seemed to aggravate the symptoms, causing more straining and some signs of collapse. On the next day (Sunday), finding treatment unavailing, the parents consented to an operation, although, from the severity of the symptoms and the semi-collapsed condition of the patient, success seemed almost hopeless. Assisted by Mr. F. H. Hume and Mr. J. B. Cook—chloroform having been administered—Mr. Brown performed abdominal section, making the incision just at the inner margin of the tumour, about two and a-half inches to the left of the middle line. After considerable difficulty the point of invagination was found, but all attempts at releasing the incarcerated gut by the usual methods failed. After the patient had been under chloroform about an hour it was decided to discontinue further attempts at reduction. It was then found impossible to return the portion of intestine which had been drawn through the incision to the abdominal cavity in consequence of extreme distension with gas. As pricking with needles seemed to cause no diminution in bulk it was deemed advisable to make a small longitudinal incision in the descending colon to facilitate the escape of gas and fecal matter (if any). This procedure at once revealed the cause of the failure to release the invaginated bowel. The inflammatory action had been so severe as to cause firm adhesion of the mucous membrane of the colon and that of the invaginated small intestine. The latter was also of a very dark colour. The bowel was then returned to the abdominal cavity, and the wound closed, except a small portion which was left as in the operation for artificial anus. The child recovered from the immediate effects of the operation better than could have been expected, but later in the evening severe retching and vomiting ensued, which speedily resulted in collapse, and death took place about six hours after the operation. Mr. Brown said the chief features of the case were the rapid and acute character of the symptoms, and the fact that although only about fifty-two hours had elapsed from the onset of the attack to the performance of the operation, firm adhesion of the intestinal surfaces had taken place. In any similar case he would have great confidence, supposing milder measures failed, in recommending the performance of the operation as soon as possible after the true nature of the case had been recognised. In future he should select the middle line for section, as offering greater advantages for manipulation than that selected in the present case.

Mr. BRYANT congratulated Mr. Godlee on the courage he had exhibited in acting on the opinion he had formed from the result of his first operation. Though but one successful issue was recorded, the facts were of a nature to support the adoption of early interference, for it could not but be felt that valuable time had been lost in dealing with the second case instanced, which might possibly have terminated successfully had speedier measures for relief by operation been resorted to. Mr. Bryant was struck by the ease with which the intussuscepted bowel had been withdrawn in all the cases; Mr. Brown's case, on the other hand, afforded an example of rapid

inflammation. The analogy between hernia and intussusception ought always to be borne in mind, and that taxis, though a valuable measure in early stages of each, would prove injurious at later periods; so, also, with intussusception, immediate resort to injection, &c., was justifiable; while, later on, nothing but operation could be expected to afford successful results. The occurrence of rare cases of spontaneous reduction should not be permitted to influence the judgment of surgeons in respect to treatment, in the direction of supplying a rule of conduct in these cases, for such terminations could only be regarded in the light of surgical accidents. The third case reported by Mr. Godlee, offered an instructive example of the fact that the extent to which invagination might occur could not always be determined with accuracy.

Mr. HOWARD MARSH said that successful instances of treatment of intussusception were rare, and that Mr. Godlee's first case proved both the possibility of performing abdominal section on infants without fatal consequences, and that mechanical treatment of intussusception offered some prospect of a favourable result. Mr. Bryant had suggested the right method of considering these cases by comparing them with hernia, for in both classes of obstruction the time would arrive when nothing but mechanical means of treatment could avail. It was no argument against such interference to urge that the issue was rarely successful. Mr. Brown's case was instructive as showing the rapidity with which inflammatory changes following strangulation might occur; Mr. Godlee's first case demonstrating an opposite conclusion. Existence of hæmorrhage afforded evidence both of strangulation and of continued circulation concurrently, as was pointed out by Dr. Hilton Fagge. It was more important to consider the duration of such strangulation than the length of time during which invagination merely had existed, the period at which the former came on being very variable. Mr. Marsh urged fearless and early operation in such cases, without undue loss of time in preliminary efforts at reduction by the milder methods of inflation and injection, for the severity of the proceeding offered no reason against its adoption, inasmuch as it alone afforded any prospect of preserving life in cases where less radical measures proved useless, as happened in the great majority of intussusceptions. He thought Mr. Hutchinson's suggestion to avoid pulling on the portions of intestine affected most valuable.

Dr. F. TAYLOR narrated the histories of three cases of intussusception under his care last year, in two of which recovery followed inflation. In both instances intussusception had lasted from three to five days, but the symptoms set up were not at all severe; the ages of the patients were five years, and eight to nine years respectively. The third, an unsuccessful case, was that of a much younger child, and was accompanied by very severe symptoms of acute suffering. Inflation was adopted with the result of reducing the size of the tumour from that of a hen's egg to that of a hazel nut; but the original dimensions were restored after a few hours. The case was seen by Mr. Golding Bird, and inflation by air attempted with a similar result, and the child died about three hours afterwards. Post-mortem examination showed that the intussusception was not at all reduced, and even the injection of water failed to remove the condition; operation in this case must have been of very doubtful value, but Dr. Taylor agreed to the importance of early operative procedure as a rule.

Dr. MAHOMED narrated a case of chronic intussusception seen by himself a short time ago. It had lasted for three months, and at one time protrusion of four or five inches of intestine had occurred. For many reasons, which he would not stay to explain, diagnosis was obscured, but the question had arisen whether it might not be well to excise the whole portion of affected bowel, first cutting down upon its site. This proceeding seemed to afford the sole chance of cure in chronic cases, and he would propose its adoption. He had seen so much injury follow mere reduction of the intussuscepted gut, that he believed it would be in every way a better plan to remove it altogether from the body.

Mr. HOWSE was anxious not to depreciate operation in these cases, but at the same time he felt there were many difficulties in the way of success. He had operated in four cases of intussusception, in one of which preliminary treatment by inflation, &c., had failed; in two of them there was protrusion of intestine from the anus. Abdominal section was resorted to eventually, and in two cases the unreduced portions of intestine were excised. He found that many difficulties must be encountered in this operation, and especially from the escape of feculent material and air at one stage of it, to prevent the injurious effect of which he

advocated the employment of a shield of rubber or other suitable material. Union of the divided intestine would also be found a difficult matter, from the resistance to its withdrawal far enough to admit easy manipulation. These considerations suggested a necessity for replacing present operations by some other proceeding, by which the need for abdominal section might be avoided; and in this connection it would be well to bear in mind the case in which an Italian surgeon, mistaking a protruded intussuscepted intestine for prolapsus ani, had drawn the gut down and cut it off, with the result that complete recovery ensued. Mr. Howse considered this operation was worthy of imitation; it was certainly much simpler and easier than that involving abdominal section, and risks of peritonitis might be much reduced by appropriate treatment of the peritoneal surface exposed by means of sutures.

Dr. ANDREW CLARK congratulated Mr. Godlee on the frankness he had exhibited in describing his unsuccessful cases, and expressed a wish that surgeons would keep careful records of all facts in respect to temperature, &c., observed in these cases, as thereby they might accumulate evidence of utility to physicians.

Mr. WARRINGTON HAWARD commented on the importance of distinguishing between mere invagination and strangulation of the intussuscepted mass, which latter condition could not always be readily diagnosed from the symptoms present. Even acute symptoms could not be held to prove the existence of strangulation, as was shown in a recent case of his own. In this instance a child, seventeen months old, was brought in with a history of acute pain and vomiting five days before. These symptoms persisted, with accompanying constipation, relieved only by the passage of a single motion, and blood had been discharged two days after the onset of the attack. Dr. Cafavy saw the patient, and at once diagnosed intussusception. Ether was forthwith administered, and inversion, &c., were tried without effect. Abdominal section was then performed, when, notwithstanding the acute symptoms so long maintained, the invaginated bowel was at once easily withdrawn. The difficult part of the operation, however, then began. Part of the distended small intestine had escaped in spite of all efforts to retain it, and it could not be returned without splitting the peritoneum. Inversion of the child was useless to force the gut back, and this was eventually punctured in several places. Even then the peritoneum was split, and a trocar had to be employed for relief of the distension, the manipulation and time thus required being both very considerable. The child died a few hours after, and commencing peritonitis was found post mortem, due, no doubt, to the handling suffered for so long.

Mr. MARCUS BECK had performed the operation once, and likewise experienced difficulty in returning the intestine to the abdomen. The child apparently died under operation, but was restored by artificial means, only, however, to succumb thirty-six hours later.

Mr. PEPPER remembered the case mentioned by Mr. Beck, to whom he was acting as house-surgeon at the time of the operation. In another case he had seen similar results occur.

Dr. BUZZARD urged the advisability of bearing in mind that cases of intussusception differed from those of ovarian disease, in which no attempt at natural recovery ever took place. No obstruction occurred as a consequence of intussusception until formation of adhesions commenced, from which time natural recovery advanced; subsequent ulceration progressed, so that the invaginated part became detached and thrown off, thus restoring the lumen of the tube. In most cases death preceded this fortunate termination, an event expressed by the French phrase, *elle mort guérie*. This tendency to natural recovery on the part of intussuscepted intestine removed it from that class of disease, in which abdominal section had been attended with such brilliant success.

Dr. GLOVER suggested the possibility of employing extract of belladonna as a remedial agent with advantage in cases of intussusception. By the success attending its use on one occasion a child, who had suffered for ten days from intestinal obstruction was saved from being submitted to abdominal incision for its relief. Large doses of the drug were given, and recovery ensued.

Prof. LISTER remarked that Mr. Howse's suggestion deserved very careful consideration, the proposed operation being in effect an imitation of the natural process to which

Dr. Buzzard had referred. He had no doubt in his own mind that peritonitis in Mr. Godlee's second case resulted entirely from the condition of the bowel, and not to manipulation of the peritoneum. Mr. Lister commented on the want of frankness displayed by surgeons who described themselves as not operating antiseptically, simply because they dispense with the spray—the least important element of the system. Such surgeons, by the minute precautions they took to ensure perfect cleanliness and asepticism, did in reality operate antiseptically.

Mr. GODLEE, replying to the discussion, said that strangulation was acute in his second case, thus supporting the opinion of the President. His (Mr. Godlee's) statements were all made with reference to very young children, in whom inflation was attended with least benefit. This treatment was better adapted to older patients, who stood it well, as Dr. Taylor's cases had shown. He could not think surgeons were justified in awaiting separation of the invaginated gut by natural processes in infants; and he admitted that difficulties in the way of diagnosing strangulation were undoubtedly great. In dealing with his own cases, he had employed but little force or traction, but rather pulled out the inner, at the same time unrolling the outer, piece of intestine. In Mr. Hutchinson's case reduction was accomplished after existence of intussusception for one month, so that time could not be taken as a proof of impossibility of successful treatment. In both his own cases temperature before operation was not above 99°, but afterwards went as high as 108° or 104°. He also had found it difficult to return the escaped small intestine.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

TYPHOID FEVER.—The whole meeting of the Académie de Médecine, on Wednesday last, was devoted to the all-absorbing question of the epidemic of typhoid fever. M. Gueneau de Mussy, who opened the discussion, called the attention of his colleagues to the influence of the different qualities of water on the present epidemic. It is well known that water contaminated with faecal matter is the most powerful vehicle of typhoid fever. There was a canal that furnished water to 600,000 inhabitants, and that water was proved to be seriously contaminated. He considered the fact to be serious enough to demand the immediate attention of the authorities, or otherwise the city would never be free from the fever. The town of Brussels and other large European cities were well supplied with pure water, and Paris should not be inferior in that respect. M. Hardy criticised the treatment adopted by M. Herard, and of which he gave an account at the last meeting. He considered the doses employed by him of salicylic acid, phenic acid, and especially sulphate of quinine, to be far from innocuous. He had visited a typhoid patient whom he found to be suffering from cerebral and pulmonary congestion; the temperature had also fallen below the normal. On inquiry he was told that she had taken 30 grains of quinine and 10 grains of phenic acid daily. He put her on cinchona and opium, and now she was recovering. Two days afterwards another patient succumbed, and he attributed the fatal result to the large dose of quinine administered two days previously (30 grains each day). In another hospital about the same time a patient died suddenly after taking 45 grains of quinine. He did not ignore the fact that sometimes patients died suddenly in typhoid fever without any explicable cause, but those cases were rare. Although he had cited only three cases that might be safely attributed to the large doses of the quinine, yet he believed that if there were not more accidents it was from the fact that in a large number of patients the absorption was not complete. In his hospital, where the treatment adopted was purgatives, tonics, enemas

(simple), and light diet, the mortality was exactly half that observed under other treatments. As to the high temperature, he never was afraid of it as long as the pulse was not in proportion. He believed that the pulse was rather neglected in these cases, all the attention being given to the temperature. In typhoid fever the pulse is often below 100, and the temperature at 102° or 103°. In such cases he generally gave a favourable prognosis. M. Hardy concluded by expressing the hope that all the heroic remedies would be abandoned, and that the old classic treatment would be continued. M. Hérard, replying, defended energetically his treatment against the attack that had just been made, and cited as authorities Barthez and Rilliet, who, with many others, employed with good results this treatment. He could not consider that M. Hardy had succeeded in proving that the fatal results of the cases he mentioned was due to quinine. As to the phenic acid, he considered it a good local antiseptic administered in enemata at the dose of 4 or 5 grains. M. Legouest did not believe with M. Hardy that the sudden deaths were to be put down to the treatment adopted, but he did not think that quinine given without acid, and in wafers, according to the method of M. Hérard, was a good plan, as it was liable to pass through without being absorbed. He cited the case of a patient who thus passed through the rectum from ten to fifteen of these wafers of quinine intact. After a few remarks from M. Beaumetz, who was inclined to coincide with M. Hérard and the last speaker, the assembly arose.

THE *Union Médicale* reports the case of a woman who was delivered of three girls and a boy. The four children together weighed six kilograms and a quarter. Three were born dead and the fourth was very feeble.

THE Lords Commissioners of the Admiralty have awarded to Dr. Henry J. Domville, R.N., C.B., Honorary Surgeon to the Queen, the Good Service Pension of £100 a year for Inspector-Generals of Hospitals and Fleets, vacant by the death of Dr. James W. Johnston, R.N., Honorary Surgeon to the Queen.

AN anonymous donor has presented the Ventnor Consumption Hospital with funds for an additional house and furniture, to meet the great pressure of applicants for admission. The Committee are anxious of receiving offers to erect two more houses, so that a complete block may be built.

SURGEON-GENERAL Sir J. A. Hanbury, K.C.B., who was principal medical officer of the Egyptian Expedition, and Principal Veterinary Surgeon J. J. Meyrick, C.B., are to remain for the present at Cairo, Sir Archibald Alison considering their presence desirable in consequence of the sickness which prevails among both men and horses of the Army of Occupation.

A POOR-LAW Conference for the county of Yorkshire will be held at Halifax on Thursday, December 21st, when papers will be read on "Recent Legislation," "The Education of Pauper Children," and on "Settlement and Removal," by the President and others; and one on "Vaccination," by Dr. T. M. Dolan; the latter is expected to provoke considerable discussion, in view of the recent Norwich inquiry.

WEDNESDAY, DECEMBER 13, 1882.

INTUSSUSCEPTION.

ON Friday evening last the Clinical Society of London was engaged during its whole meeting with a discussion on intussusception, to which a paper read by Mr. Godlee gave rise. In this communication Mr. Godlee described three cases of abdominal section for the reduction of invaginated intestine, performed by himself on young children, with the result that one recovery and two deaths ensued. It would be ungenerous for us to withhold an expression of admiration at the fearless honesty and frankness which was exhibited by the author of the paper in thus publishing the disasters attending his treatment in the two unsuccessful cases; and it will be generally felt that the encomiums so gracefully and happily addressed to Mr. Godlee by Dr. Andrew Clark in this connection were universally deserved by their subject. Mr. Godlee, however, was less than just to himself in describing as a blameworthy error his *failure* to distinguish in one of his cases that the whole of the invaginated portion of intestine had not been retracted during operation. In his account of the case he draws attention to this omission with the intention, apparently, of charging to his own account the commission of a fault which may only too readily be forgiven him. It would need more than human skill and intelligence to avoid the possibility of such an error under all circumstances, for at the best the sense of sight can be depended upon in such cases to a far less degree than the tactile sensibility of the operator. With only his fingers to guide his judgment he may

very well be mistaken concerning the amount of reduction accomplished; and though the continuity of peritoneal surface may be urged as conclusive proof that the invagination has been completely unfolded, yet it is by no means an impossible or improbable accident that to the touch this continuity might seem to exist, while a portion of the intussusception remained within the containing gut. It cannot, therefore, be regarded as a blunder of an unpardonable description that in one of the three cases narrated the accident occurred, but rather as a demonstration of the extreme difficulty attending the relief of intussusception in children so young as those dealt with by Mr. Godlee.

The discussion to which we refer turned mainly on two points, these being whether, and when, operation for the reduction of invagination should be undertaken. That the prospect of successful interference diminishes in proportion as it is delayed, may be taken as the general opinion expressed during the debate, although Dr. Buzzard urged that the natural tendency to recovery by sloughing of the invaginated intestine removed cases of intussusception from the category of those diseases which imperatively demanded operative treatment through abdominal section. Even he, however, made due allowance for the rarity of this termination, the frequency of which is certainly not of a character to justify much hope from such expectant methods. Particularly also is it futile to trust to it in the case of very young children, whose vital powers are wholly unequal to lasting through the time essential for the development of all those inflammatory changes in the strangulated gut which must necessarily precede its removal by natural effort. Several speakers appeared to lose sight of the fact that the question in hand was that of the treatment of intussusception in infants, and thus they launched into discussion of subjects which were in reality extraneous to the paper.

In all Mr. Godlee's cases except the last the intussusception was of the common ileo-cæcal variety; in each it was manipulated through a median abdominal incision but in one only was the operation preceded by attempts to reduce the invagination by milder modes of treatment—viz., in the first and successful case. We were frankly informed that, encouraged by this success, Mr. Godlee forthwith proceeded to repeat the operation on the next case that occurred in his practice, without loss of time in preliminary attempts; in this one death ensued. The third case hardly deserves to be ranked as a failure, the condition of the bowel being so hopelessly bad that no hope of recovery could be entertained.

To what extent, then, is immediate operation justifiable? In deciding on the answer to the question, it is necessary to consider the consequences of delay; and they are undoubtedly serious. The onset of strangury is by no means easily detectable, several instances having been quoted on Friday to show that even acute suffering affords no positive criterion that it exists. But, as a general rule, in the case of young children it may be accepted that in the event of inflation and injection proving unavailing after a trial or two, operation should be straightway resorted to. This conclusion would

probably have been all but universally rejected a decade or so ago, whereas now that abdominal surgery is no longer the *bête noir* of operators, but few practical surgeons will be found to deny the justice of the decision. There are, however, not a few still who duly regard the teaching of every fatality which follows exposure of the great serous cavities: and among them must be named Mr. Howse, who offers a suggestion that, as Mr. Lister remarked, was well worth further consideration, with the object of avoiding any direct interference with the peritoneum in the treatment of intussusception. Mr. Howse recommends that the invaginated intestine should be seized through the rectum, and so drawn out and cut off at the anus. The exposed peritoneal surfaces are next to be carefully and closely united; and the result would be in Mr. Howse's opinion a sound and successful intestine. This proceeding, it should be added, is suggested by the termination to a case narrated by Mr. Hutchinson, in which an Italian surgeon, mistaking a protruding intussusception for prolapsed anus, treated it in the manner described by Mr. Howse, the result being as explained. It is a little difficult, perhaps, to see how such a mode of treatment can be generally trusted to; for it must certainly occur that in cases where adhesion is at all considerable traction on the protruding anus would itself determine the formation of additional invagination, and this might not improbably necessitate subsequent renewed operative interference. As yet the single example of this mode of treatment does not entitle it to rank higher than as a curiosity in surgery; and in spite of the eminent authorisation given to it, it would be an unwise proceeding to attach too much importance to it as an operation.

Mr. Warrington Haward struck a timely note of warning when he drew attention to the excessive difficulty sometimes experienced in returning the small intestines which have escaped from the abdominal cavity during manipulation of the intussusception. In his own experience this really offers the worst obstacle to a successful termination, particularly as in their distended condition the coils of intestine exert a high degree of tension on their peritoneal investment. In the very interesting case recorded from his own experience, Mr. Haward was compelled, even after aspirating the bowel in several places, to employ a trocar for the removal of the contained gases; and even then the protruding mass was not returned until the peritoneum had been injured in more than one situation, the child dying soon after with symptoms of commencing peritonitis. This serious complication received a due amount of recognition from the surgeons who followed in debate, and ought to be carefully borne in mind while estimating the risks of the operation.

Dr. Mahomed suggests bold excision of a foot or more of the implicated bowel, as may be found necessary, and the startling nature of the proposition ought not to preclude it from consideration when we take into account recent improvements in the operation of enterotomy. In this connection Mr. Treves, of the London Hospital, has introduced a method of uniting the cut extremities of the intestine, which offers the certainty of far more perfect

coaptation than has ever yet been attained, the two ends being maintained in apposition during application of the sutures by aid of a most ingeniously-devised inflated rubber tube. As this operation was discussed at the Medico-Chirurgical Society yesterday (Tuesday) evening, we may with advantage to our readers return to it again.

The debate on intussusception at the Clinical Society must be accepted as resulting in a very valuable addition to our knowledge of the subject, and the features surrounding its operative treatment. Its tendency was admirably shown in the effect it produced on Mr. Godlee, who declared that in view of the expressions employed, and the encouragement given by his critics, he should not hesitate in the future to again perform an operation from which he would otherwise have been deterred by the ill-success he had already experienced with it.

THE HEADACHES OF ADOLESCENTS.

SURGEONS have long noted the relationship subsisting between the period of growth, or that of adolescence, and certain affections of the skeleton, such as deformities of deviation, exostoses, &c. Physicians have been equally cognisant of a like influence exerted during that period of life on the progress of acute diseases and the development of nervous affections. Under the latter category there exists one affection of a special nature, which has hardly yet received the attention which it merits. We refer specially to the cephalalgia or obstinate headaches which affects youths between the ages of eleven and sixteen, and which, by their intensity and the obstinacy sometimes acquired, cause them to be considered as a special morbid entity. Professor Charcot, of Paris, has directed especial attention to this subject, and Mons. Keller purposes prosecuting the study of these cases in a forthcoming number of the *Archives de Neurologie*. In the meantime we shall glance at the salient features presented by this affection. A youth, possibly from eleven to twelve years of age, hitherto in excellent health, intelligent, and acquiring knowledge with facility, is suddenly seized with severe headache. Frequently they are at first light and transient, and do not interfere with study; soon they become more frequent, more obdurate, and ultimately compel a cessation of intellectual application. There is now established a chronic malady, painful for the sufferer, and serious in its consequence, inasmuch as it interposes a barrier to all scholastic applications. The character of the headache is frontal. It never affects the posterior or lateral regions of the head. It is furthermore painful in the real acceptance of the term, a fact by which it is distinguished from other nervopathies, such as the cerebral paresis of adults or the ordinary neurosthenia, in which the sensations are vague and localised in the occipital and parietal regions. The pain is aggravated by mental application. When the malady is very pronounced the least study reacts painfully on the affected part. Sleep is enjoyed; the pain is usually absent or feeble on awakening, but occurs during the morning, especially if mental occupation is indulged in, and acquires its maximum intensity towards evening. The affection is distinguished from ordinary neuralgia in that there is no hyperæsthesia along the nervous tracts, and

from the ordinary migraine in not being unilateral nor propagated through the optic nerves, nor accompanied with sympathetic derangements of the stomach. The absence of febrile disturbance, the complete integrity of the intelligence, and the cure, which appears to be the rule, exclude the idea of any organic affection of the head.

With respect to the etiology of the disease, in some cases the rheumatic diathesis may be encountered, while in others this is totally absent, both in the patient and the family history; nor is an hereditary predisposition to nervous affections always to be traced. We are thus compelled to seek an explanation in the period of life through which the patients are passing. Thus, under the influence of some modification of general nutrition in connection with growth, the brain, owing to some given idiosyncrasy, may become weakened or painfully irritated. The situation of the pain corresponds with the portion of the brain especially active, as the seat of reflection and intelligence, during the period of adolescence. Be that as it may, it is quite certain that, should this peculiar pain exist independently of intellectual application, it is invariably aggravated by it, and it becomes the chief agent of the disease, and maintains and prolongs it. If the affection were due exclusively to a condition of growth, it should disappear with the progress of age. This does happen, doubtless, occasionally; yet in other cases the affection is so persistent that educational pursuits have to be totally abandoned for an indefinite period, as late in life even as the age of twenty-five. In these days of cramming this species of headache possesses interest to parents and guardians of children; and Mons. Keller assures us that no form of treatment has been so successful in his hands as the methodical application of hydropathy.

PERSISTENT VOMITING OF PREGNANCY.—I.

UNDER the above heading, we gave a short time ago (November 1st), a brief account of the recent labours of two Russian physicians (Professor Horwitz and Dr. Sutugin) on this subject. The appearance of the fourth edition of Dr. Graily Hewitt's well known and justly appreciated "Diseases of Women," containing as it does an entirely new chapter on "The Vomiting of Pregnancy," is our excuse, if any be needed, for returning so soon to the subject. It is now eleven years since Dr. Hewitt presented his paper to the Obstetrical Society of London, in which he first offered what is now known as his "Explanation of the Cause of the Vomiting of Pregnancy." The propositions he then laid down were: "That nausea and vomiting are associated with pregnancy; that nausea and vomiting are associated with disease of the uterus." From this he proceeds to the inference, that "the condition which gives rise to nausea and vomiting in cases of uterine disease is possibly the cause of the symptom in the more ordinary case of pregnancy." A careful observation and comparison of facts led him "to frame the theory that the sickness of pregnancy is due to the combined effects of the increasing distension of the uterus, and an associated flexion of the organ." Since the publication of this paper, its author has carefully weighed the importance of all the facts bearing on this question that have come under his own

observation, whilst he has allowed but little, if anything, to escape that has appeared in the way of criticism and published cases, either in British, or American, or Continental literature.

This chapter, some account of which we propose to lay before our readers, contains an important series of ably-observed facts, and a thorough re-examination of the theory first made public in 1871—thus made long after the blush and charm of novelty have passed away. First, as regards the name. Dr. Hewitt calls it "Severe or Dangerous Vomiting in Pregnancy. Perhaps upon the whole no better name can be found for it than that of "Pernicious Vomiting of Pregnancy." This sufficiently indicates its grave character, without having such an objectionable sound at the bedside; it has, moreover, one merit in that it is not new. As a basis for his researches, he has made use of the data afforded by thirty-one cases observed either by himself or others. In regard to supposed etiology, the thirty-one cases may be divided into four classes of very unequal dimensions.

Class I. comprises all those cases in which retroversions or retroflexions were found to be present, and to which the vomiting was attributed. These were four in number, and were the cases numbered 1, 2, 25, and 27. In Case 1 the vomiting was cured by redression of the uterus, in Case 4 by causing the patient to lie on her face. In Case 2 abortion was produced by art, and in No. 3 it occurred spontaneously.

Class II. comprises those cases in which anteversion or antelexion was ascertained to be present, and in which it was supposed to stand in causal relation to the sickness. This class is much larger than the other, and embraces eleven cases—viz., Nos. 5, 7, 8, 9, 11, 13, 14, 26, 28, 29 and 30. The first of these (No. 5) was a case recorded by Ulrich, which ended fatally. The post-mortem examination revealed a striking condition of things. Nothing worthy of note was discovered in any except the genital organs. "The body and fundus of the uterus—considerably enlarged—lay directly behind the right horizontal ramus of the pubes, much antelexed; the length of the body of the uterus was five and a-quarter inches; the position of the flexion was three inches from the os. On the under surface the walls of the uterus were soft and flabby; on the upper surfaces they were much condensed, and very firm. On opening the cavity of the uterus the placenta was seen to have had its attachment to the lower segment of the uterus, and thus had harboured the fœtus. Above the seat of flexion in the upper segment of the uterus no free cavity existed; the small interval between the rigid walls of the uterus was filled with a mass like a placenta firmly adherent everywhere." Dr. Hewitt remarks on this case that "it is my decided opinion that the bending of the uterus, and consequent hindrance to the regular expansion and growth of the uterus, was the influence producing the obstinate vomiting." The second case, No. 7, was one observed by the author himself in consultation. Antelexion was discovered, and postural treatment recommended. The result of the treatment was that "the sickness underwent at once a most material alleviation, soon disappeared, and delivery at full term occurred." The third (No. 8) was published

by Dr. Moore in 1872. The uterus was acutely antelexed. All attempts at redression failed, and the vomiting continuing, artificial abortion was induced. The fourth (No. 9) was one reported by Dr. M'Clintock. The uterus was found to be "slightly anteverted." Treatment was of no avail, and the patient being in a highly dangerous state, abortion was induced. In this case "the uterine tumour could not be distinguished above the pubes," and the author remarks that it is probable "that the body of the uterus was really abnormally low in the pelvis." In connection with this case Dr. Hewitt replies to the objections made by Dr. M'Clintock and to his theory, viz.—that in retroflexion of the gravid uterus vomiting is not always present. He acknowledges the force of the objection, but replies that even in the non-gravid uterus he has met cases of retroversion accompanied by most severe and distressing sickness, which have been relieved almost magically by redression of the uterus; that "neither in the gravid nor in the non-gravid state is sickness an invariable symptom, but this does not prove that the flexion is not responsible for the sickness when it does occur." The fifth (No. 11) was one of the late Dr. Copeman's cases, in which "there was some degree of anteversion." Dilatation of the os relieved the sickness. The next was also one of Dr. Copeman's (No. 13). In this case the head could be felt *per vaginam* below the level of the os uteri. A cure followed redression. The next case (No. 14), also one of Dr. Copeman's, was one in which the fundus was displaced forwards. The displacement was rectified. The next day the sickness was much less, but as it continued slightly, dilatation was performed, which was followed by cure. The next case (No. 26) was that of a patient admitted into University College Hospital. The vomiting was very severe and persistent. Anteversion of the uterus was diagnosed by the resident medical officer, but when Dr. Hewitt examined her the uterus had already escaped out of the pelvis. After this she vomited only about three times and gradually recovered. The next (No. 28) was one in which antelexion was discovered; the os uteri was swollen, and the anterior cervical wall thin. No mention is made of any attempts at redression being made in this case; tents, however, were introduced, but without effect. The history is further imperfect with regard to results. The tenth case (No. 29) was one of very severe sickness arising from antelexed uterus, with great hypertrophy and hardening of cervix and os. The report of this case is also imperfect. No mention is made of redression; the cervix was, however, dilated by means of a metallic dilator. Relief followed the day after, but abortion occurred on the second day. The patient died a little over a fortnight later from exhaustion. In the last case (No. 30) the uterus was antelexed, and "the body of the uterus quite low down in front, while the os uteri is far back, the uterus being thus jammed downwards behind the symphysis pubis." Postural treatment was employed with success.

AN "emplastrum impermeabile russicum" is being introduced upon the Continent which is said to be likely to throw English plaster into the shade.

Notes on Current Topics.

Mr. Seymour Haden in America.

MR. SEYMOUR HADEN, who is so well known as a skilful etcher, has been lionising in New York, where the Lotos Club recently afforded him a reception. Mr. Haden seems to have excited the enthusiastic admiration of the honest New Yorkers, who are ecstasically surprised at the combination of artist and surgeon that he embodies. Following so soon after his eminently-distinguished fellow-countryman, Herbert Spencer, and placed in a somewhat similar position to that occupied by the latter at the farewell dinner given in his honour at Delmonico's, Mr. Haden seems to have deemed the occasion a fitting one for disagreement with the views on America enunciated by the Apostle of Evolution. These views we recently referred to somewhat briefly, and it will, therefore, be of interest to quote Mr. Haden's rejoinder. He is reported to have declared that the very reputation for energy found fault with by Herbert Spencer had been a great attraction for himself, and regretted that it was not a feature of British character. Mr. Haden continued: "I disagree *in toto* with Mr. Herbert Spencer. It has been my business and my pleasure to see the effect of work, and to judge of it, and I can honestly say that I never saw in all my professional career the least injury to life or health result from what Mr. Spencer calls overwork." This somewhat extraordinary admission of limited experience was then supplemented by the citation of a case in which the speaker described himself as having been in consultation with Sir William Gull, who likewise uttered the same curious opinion. In the presence of two such authorities it is perhaps vain to discuss the question; but certainly we may be permitted to doubt the utility of wide publication being given to views that are not, to say the least, of common acceptance.

Homœopathy Despondent.

THE homœopathic brotherhood are uneasy because they have *no locus standi*, and this they have decided to seek for in the shape of an Act of incorporation at the hands of the Board of Trade. It seems that the London School of Homœopathy, which is to all intents and purposes the fountain of inspiration of the creed in this country, is unhappy in that it is not in a position at present to reward its adherents in the way they deserve to be rewarded, and it is desirous of being incorporated, that its supporters may henceforth hoist the healing signal "L.H." or "F.L.S.H.," which signify respectively "Licentiate of Homœopathy" and "Fellow of the London School of Homœopathy." It is somewhat of a blow to infidel outsiders to learn that there is any necessity for thus artificially stimulating what we have been again and again assured of late is a vigorous and exceedingly healthy association. At the same time, it is encouraging to note that the few really eminent homœopathic physicians are steadfastly opposed to this fanciful scheme of incorporation, which is after all scarcely calculated to enhance the fading dignity of the fated school. The *Homœopathic Review* is not unnaturally highly wroth with the minority who are opposed to levelling down the pro-

fession of homœopathy to that of a trade, because it probably fears that without some such help to existence the forthcoming extinction in store for the whole structure would be hastened.

Porro's Operation.

THE patient on whom Dr. Clement Godson recently performed Porro's operation on account of contracted pelvis, and to whom we referred in our last issue, has progressed steadily towards recovery, and but little doubt is now felt in her ultimate complete restoration. The child also is healthy and doing well.

The Sanitary Diploma of the Irish College of Physicians.

MR. GEORGE R. PRICE, Barrister-at-Law, and Mr. Mervyn J. B. Pratt, C.E., and Master in Engineering of the University of Dublin, have been appointed, respectively, Examiner in Sanitary Law and Examiner in Sanitary Engineering, for the certificate of Sanitary Science of this College.

Clinical Teaching at Oxford.

IT is with feelings of the liveliest satisfaction that we note many signs of determined activity with the object of restoring to Oxford its proper position among British schools of medicine. For too long a series of years have the numerous endowments originally bequeathed for the purpose of advancing the study of medicine been allowed to be disbursed without due consideration being had to the objects of founders. It is notorious that, beyond the work done by one or two students per term in dissecting a single body in the museum cellars, absolutely no medical studies are conducted at Oxford, and in particular have the facilities afforded at the Radcliffe Infirmary for clinical work been persistently neglected. Now, however, the appearance of a change is becoming evident, and it is possible to hope that ere very long the wards of the hospital will not exist in vain so far as study is concerned. A statute has been laid before congregation, and has passed the first stage, of which the object is to sanction the appointment of clinical lecturers from the staff of the Infirmary, and to remunerate them for services rendered in such capacity from the Lichfield Trust Fund. When the provisions of this statute shall once have come into force, it is easy to see that most important changes will come over the whole face of medical study in the University; and, taken in conjunction with the recent appointment of Professor Bardon Sanderson, it may be regarded as of most favourable import for the future.

THE will has been proved of the late Mr. Joseph Thomas Olover, F.R.C.S., of 3 Cavendish Place, Cavendish Square, W., the personality exceeding £27,000.

THE Court of the University of Edinburgh have announced that they will, on the 22nd of January, 1883, proceed to the appointment of the additional Examiner in Medicine in each of the departments of chemistry, anatomy, midwifery, and practice of physic.

Great Fires.

DURING last week the metropolis was the scene of two large conflagrations, one involving the total destruction of the well-known Alhambra Theatre, and the other that of an almost fabulous amount of valuable manufactured stuffs. The money value of the buildings and goods thus destroyed by fire and water is put at nearly three million pounds, and it is hardly surprising that the story of so great pecuniary calamities should be mingled also with accounts of human suffering in various ways. Even during the progress of the fire two persons at least received fatal injuries, these unfortunate men being members of the Fire Brigade present at the burning of the Alhambra. In the other, the City fire, no life was lost or very serious injury sustained. A vast number of persons will be thrown out of employment through these disastrous fires, and strenuous efforts will be requisite to preserve many of them from suffering by want and exposure. We trust the appeals made on their behalf will be liberally responded to.

Treatment of Writer's Cramp.

HITHERTO the successful treatment of scrivener's palsy has been rendered more difficult from the necessity of enforcing abstinence from writing during its course. As the affection generally, or almost invariably, attacks those who write much, and, moreover, write for their living, it follows that suspension from employment is a very serious matter, and very frequently interferes disastrously with a successful issue of this case. To obviate this difficulty, Professor v. Nussbaum, of Munich, has invented a bracelet to which a pen may be fastened, and which allows of a patient carrying on his employment without affecting injuriously the successful treatment of the disease. The bracelet consists of a stiff band of gutta-percha about $\frac{1}{4}$ of an inch thick (3 mm.), 1 inch to $1\frac{1}{2}$ inch broad, and $3\frac{1}{2}$ to 4 inches in length. It should be wide enough to allow the four fingers and the thumb to be passed in. (These are the dimensions given in the *Deutsche Med. Zeitung*, from which this account is taken; but any one taking the measurements for himself will see that the length meant must be the length when the bracelet is flattened out on itself, so that the circumference will be just double the $3\frac{1}{2}$ to 4 inches, as given above.) In use, the little finger should not enter the bracelet at all, the thumb only a little way, whilst the ring finger should be passed in almost up to the metacarpal bone. The bracelet can only now be held firmly by extending the fingers, thus making use of the extensors of the fingers and the abductor of the thumb. As soon as the flexors are made use of, the bracelet falls. A pen is now sewed on to the bracelet in such a way that it just touches the paper when the hand is lying on the writing-table. The more the fingers are extended, the more firmly is the bracelet held, and the better does the patient write after a little practice. Thus is that proper antagonism between flexors and extensors of the fingers and between abductors and adductors and opposens of the thumb secured, which should be the best way of treating the disease. By this means, writing need not be prohibited, but rather writing by means of the bracelet should be encouraged, as, after the proper antagonism between the two sets of muscles is re-established, writing in the ordinary way may once more be recom-

menced. This method of treatment, combined with massage of the hand, baths, and faradisation, has, in the hands of von Nussbaum, been very successful.

The following five points encourage him to make known the method to his professional brethren:—

1. Every individual who had suffered from scrivener's palsy, and could not even scratch his name, much less write a couple of lines, wrote, to his great astonishment, with the bracelet, at once and without trouble, a couple of pages, &c.
2. No trace of cramp was ever observed whilst writing with the bracelet.
3. Every one declared whilst writing with the bracelet, even in those portions of the hand that had been before accompanied by torment, that the sensation was extremely agreeable.
4. After some little time some of the patients acquired the feeling that they could write again in the ordinary way without spasm.
5. It is certainly rational to relieve those muscles from work that have been affected by spasm, and to strengthen the weakened antagonism by diligent gymnastics, and this is what does take place in writing with the bracelet.

Lectures at the London College of Physicians.

THE arrangements for the customary series of lectures at this College are now complete for the first quarter of the New Year, and we understand that the following have been definitely decided on:—The Gulstonian Lectures will be delivered by Dr. J. Matthews Duncan, on Feb. 16, 21, 23, the subject being "Sterility in Woman;" the Croonian Lectures by Dr. J. E. Pollock on Feb. 28, March 2, 7, subject, "Modern Theories and Treatment of Phthisis;" and the Lumleian Lectures by Dr. A. B. Garrod, on March 9, 14, 16, on "Uric Acid in its relation to Renal Calculi and Gravel." The entire series will be delivered at the same hour, five o'clock, on the Wednesdays and Fridays of the foregoing dates; members of the profession being admitted free on production of visiting card.

Important for Smokers.

THE *Deutsche Med. Zeit.* says that in the chemical laboratory of the Board of Health, in Bremen, Dr. Kissling has made investigations in regard to the danger of smoking cigars. As grave poisons he found carbonoxyd, sulphuretted hydrogen, prussic acid, picrolin bases, and nicotin. The first three cannot come into consideration, as they are too volatile, and present in too small quantities. Regarding the nicotin, however, he found that a very small trace only is burnt up by the smoke, but that the stump becomes the richer in this narcotic substance, the larger the cigar is, the more the end is chewed, the shorter the stump gets, and the oftener the cigar is lit. Conclusion: to avoid all danger, smoke a cigar not too thick and long, do not chew the end, smoke only two-thirds of every cigar, and throw it away as soon as relighting becomes necessary. Never smoke a cigar after it has once gone out. *Cigarettes are the least injurious of all tobacco smoking.*

Antagonism between Atropia and Pilocarpin.

THE *Deutsch Med. Zeitung* reports that Dr. M. Levinsky, of Warsaw, has been making a series of experiments in Professor Navrozki's laboratory, in the University of Warsaw, with a view of settling the vexed question of the antagonism between the two above-mentioned drugs. The experiments gave the following results:—1. Atropia, even in very small doses, diminishes the secretion of saliva, and paralyzes the chorda tympani nerve. Large doses of pilocarpin injected after atropia re-establish the salivary secretion, but not the irritability of the chorda tympani. If large doses of atropia have been employed pilocarpin will not restore the activity of the salivary glands. 2. If pilocarpin be injected first, much larger quantities of atropia are required to suppress the salivary secretion.

Notification of Infective Diseases.

WE note with great satisfaction the growth of the opposition on the part of the profession to the proposal to make physicians sanitary detectives. The defeat of the sanitarian Quixotes at Liverpool has been followed by their rout in Glasgow. Our correspondent reported last week the action of the profession against the notification clauses of the Police Bill, and we learn that, in consequence, the Bill has been withdrawn. It will not be presented to Parliament during this session at least, on account of the intention announced by the Lord Advocate to prepare a Police Bill applicable to all the large Scotch towns generally. The deputations which waited on the Town Council, however, found that body quite enamoured of the powers these compulsory notification clauses conferred on their officers; and it is not at all improbable that had the Lord Advocate not upset the Council's calculation we should ere long have been saddled with dual responsibility, under penalties both severe and cumulative.

Irish Academy of Medicine.

THE Committees of Subsections of Anatomy and Physiology and of Public Health were elected last week by the Councils of the Surgical and Medical Sections conjointly, and of the Pathological Section respectively, as follows:—*Anatomy and Physiology*—Chairman, A. MacAlister; Committee, D. J. Dunningham, A. MacAlister, Ph. Abraham, J. E. Purser, J. Knott, J. MacArdle, F. Houston. *Public Health*—Chairman, Charles A. Cameron; Committee, J. W. Moore, T. W. Grimshaw, J. F. Pollock, T. Purcell, Geo. F. Duffey, J. H. Chapman.

The Hospital Saturday Fund.

THE Board of Delegates of this Fund met on Saturday last, under the presidency of Mr. H. N. Hamilton-Hoare, treasurer, to consider the report of the Council for 1882, and the awards of the Distribution Committee. The report showed that the total receipts were £8,872, exceeding those of 1881 by £500, and those of 1880 by £2,000. Of the entire income £6,318 was derived by means of collection sheets supplied to workshops, &c., and £2,160 resulted from the street collection, being £144 in excess of the previous year. There were 900 stations occupied by

ladies on the 2nd of September, as against 650 upon the previous Hospital Saturday. £900 of the street collection was in coppers, and included 5,000 farthings. In nearly 3,000 London workshops there were collectors of the Fund entitled to distribute when needed to their fellow-workmen "letters" securing to the recipients the benefits conferred by the hospitals and dispensaries participating in the receipts. Awards, amounting in the aggregate to £7,250, were made to 67 hospitals, 37 dispensaries, 6 convalescent homes, and 2 surgical-aid societies. No institution applying to participate in the Fund had been disqualified. The amount of distribution adopted was based upon the relief afforded and the efficiency and economy of the various participating institutions; and it ranged from £400 9s. 2d. to the Brompton Consumption Hospital, to £22 19s. 2d. to the St. Andrew's (Folkestone) Convalescent Home.

The Growth of the Temperance Cause.

WE note with great pleasure that in the Speech from the Throne, last week, the Queen said—"The growth of the revenue, however, is sensibly retarded by a cause which must in itself be contemplated with satisfaction: I refer to the diminution in the receipts of the Exchequer from the duties on intoxicating liquors." The circumstances must, we imagine, have been very convincing which induced the Ministry to refer to this subject in her Majesty's speech, and that they did so is a sign that teetotallers are now worth cultivating as a political power.

Medical Society of the College of Physicians in Ireland.

AT a special meeting of this Society, recently held, resolutions were adopted, that, in consequence of the formation of the Academy of Medicine in Ireland from among the members of this Society and of the other medical societies in Dublin, the Medical Society is now dissolved, and that the books of the Society be entrusted to the care of the College. The Medical Society, which has thus ceased to exist, had a chequered history extending over sixty-six years. It was instituted in the year 1816 as the "Association of Fellows and Licentiates of the King and Queen's College of Physicians in Ireland," and was reconstituted in the year 1864 under the title of the "Medical Society of the King and Queen's College of Physicians in Ireland."

HER MAJESTY THE QUEEN has forwarded a quantity of old linen from Windsor Castle for the use of the patients in University College Hospital.

As scarlet fever, which recently prevailed at Haarlem Hospital, and prevented the contemplated visit of the Queen to the sick and wounded Marines and seamen there, has now disappeared, an official communication has been received, stating that no further discharges of the sick and wounded men of the services in question are to be made at the hospital until her Majesty has visited the establishment. No date is yet fixed, but the Queen is expected to arrive at Osborne to spend the Christmas about the 18th inst.

A Spoon in the Stomach.

On the 10th of September of the present year a youth, whilst playing with a spoon, swallowed it. He was taken at once to the Hôpital Lariboisière, Paris, where he complained of pain in the epigastrium and tightness of breathing. During the day, vomiting set in, the patient could not sleep, and there were no signs of the offending article changing its position. The size of the spoon, too, made its passage either way very problematical. It was 9½ inches in length (24 ctm.). M. Félicet, in whose charge the patient was, determined upon gastrotomy. Before the operation was commenced the stomach was washed out with Vichy water. After the peritoneum was reached and the bleeding had been checked, the stomach was distended with ether vapour, which was forced in by means of a pump. The peritoneum was now divided on a director, whereupon the now distended stomach-wall bulged through the opening. Before being opened, the stomach was stitched to the abdominal wall, and the firmness of the stitches was tested by further distension of the stomach with ether vapour. The stomach was then opened, and the spoon removed. Lister's dressing was employed. The further course was favourable, and the patient was discharged after three weeks with only a small fistula remaining.

The Owens College Museum.

At a meeting last week in the parlour of the Mayor of Manchester resolutions were carried to the effect that it is desirable that a museum be erected in connection with Owens College, and that a fund of not less than £50,000 be raised for the purpose. The buildings are to be constructed from a design by Mr. Alfred Waterhouse, under instructions from the Court of Governors of the College. Promises of sums to the amount of £20,000 have been received, and for the remainder of the costs a canvass will be made.

The Bradshaw Lecture at London Royal College of Surgeons.

THIS lecture will be delivered for the first time by Sir James Paget, at the Royal College of Surgeons, at three o'clock on this day (Wednesday). The subject of the lecture is "On some Rare and New Diseases," illustrated, as we understand, by the contents of the museum of the College.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Bolton, Portsmouth 14; Leicester 17; Birkenhead, Bradford, Derby 18; Brighton, Bristol, Salford, Wolverhampton 19; Edinburgh, Plymouth, Birmingham 20; London 21; Sheffield Preston, Norwich 22; Huddersfield 23; Leeds, Oldham, Nottingham 24; Dublin, Hull 25; Manchester 26; Glasgow, Blackburn, Cardiff, Halifax 27; Liverpool, Newcastle-on-Tyne, 28.

THE London Gazette of Friday, December 1, contains the announcement that the Queen has been pleased to order the appointment of John Watt Reid, Esq., M.D., Medical Director-General of the Navy, to be an Extra Member of the Military Division of the Second Class, or Knight Commanders, of the Most Honourable Order of the Bath.

THE highest annual death rates per 1,000 in the large towns last week from diseases of the zymotic class, were—From scarlet fever, 1·4 in Oldham, Halifax, and Sheffield; from measles, 1·8 in Cardiff, and 3·1 in Sunderland; from whooping cough, 1·4 in Halifax, and 1·6 in Preston; and from fever, 1·4 both in Halifax and Newcastle-upon Tyne, and 1·9 in Liverpool. The 36 deaths from diphtheria included 18 in London and 11 in Glasgow. Small-pox caused 5 deaths in London, 4 in Newcastle upon Tyne, and one in Nottingham.

IN accordance with custom, the next (the sixth) annual meeting of the Dublin Branch of the British Medical Association will be held on Thursday, January 25th, 1883, at the Irish College of Physicians, when the President-elect, Dr. Banks, Physician in Ordinary to the Queen in Ireland, will deliver an address. The Branch now, under the presidency of Dr. Kidd, numbers nearly 180 members; and a large accession of new members, which it is expected will bring its number up to at least 200, before the annual meeting, is confidently looked for.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Bombay 24, Madras 29; Paris 24; Geneva 16; Brussels 21; Rotterdam 27; The Hague 33; Copenhagen 22; Stockholm 25; Christiania 15; St. Petersburg 44; Berlin 21; Hamburg 22; Dresden 27, Breslau 30, Munich 25, Vienna 22, Prague 28, Buda-Pesth 24, Trieste 27; Rome 21; Turin 23, Venice 33; New York 21, Brooklyn 23, Philadelphia 18, and Baltimore 31.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE NOTIFICATION OF INFECTIOUS DISEASES.—The question of the notification of infectious diseases has occasioned some commotion among the profession in Glasgow.—At a meeting of the Glasgow Town Council held on the 5th inst., Dr. Fergus and Prof. Gairdner appeared as a deputation from the Faculty and made the following representations:—Dr. Fergus, promising that in company with Dr. Gairdner he appeared as a deputation from the Faculty of Physicians and Surgeons, said he was anxious not to occupy the time of the Council, and therefore he would confine himself to giving them the result of his experience as a district surgeon for nearly twenty years, during which he ministered to the poorest of the inhabitants. In 1873, acting upon that experience, he called the attention of the Police Board to the large number of uncertified deaths, and this matter of uncertified deaths had a clear bearing on the proposal to make notification of illness by medical men compulsory. His experience was that people did not inform medical men of illness in their families so long as they could possibly help doing so. Even under present rules, he believed there was a large amount of concealed disease, and he was satisfied that if the provision in the Police Bill as to compulsory notification by medical men were retained, the amount of concealed disease would be enormously increased, and many other difficulties would be created. He believed, however, that with the present sanitary staff householders might be educated up to the point of giving notice of disease. Professor

Gairdner also addressed the Council. He said that having been at one time the medical officer of health for the city, he did not wish to appear in apparent antagonism to the methods devised in the sanitary interests of the community, but he was convinced that the proposed measure, as it stood at present, would not operate in the direction intended. Professor Gairdner referred to a visit he made with Dr. Macgill through the districts of the city where relapsing fever was prevalent some years ago, and the result of that visit was to show that not one case out of twenty was attended by a medical man, so that compulsory notification by the medical attendant would in these cases have been absolutely ineffective. The real object, it appeared to him, was to educate the householder partly by compulsion by law and partly by force of opinion. It was perfectly just that a householder who had a case of infectious disease in his house should be considered in law "the author of a nuisance," and the power of the law, so far as possible, brought to bear upon him. Compulsory notification by medical men would also tend to set up a feeling between the poorer class and the medical profession which it was most undesirable should be the case. The Lord Provost assured the deputation that the representations they had made would have every consideration, but he had not the slightest doubt, at the same time, that his brethren of the Council would also take notice of reports from other quarters where the proposed method of notification was in operation.

DR. FERGUS.—An Order in Council reappoints Dr. Andrew Fergus to be again for five years a member for Scotland of the General Council of Medical Education and registration of the United Kingdom.

DIPHTHERIA IN DUNDEE.—At a meeting of the Sanitary Committee of the Dundee Police Commissioners, held on the 5th inst., the medical officer called attention to the great mortality in cases of diphtheria. Sixteen cases had been reported in November, of which fourteen proved fatal; and during October seven cases had been reported, six of which had proved fatal. The cases were not confined to any particular locality, but occurred throughout the town. The medical officer attributed this outbreak of diphtheria to defective or objectionable house drainage, and urged the necessity of prompt measures being taken to improve the drainage. The Committee, after full consideration, gave special instructions to the sanitary inspector to investigate as to the drainage of the houses where the cases of diphtheria had occurred, and also in all other suspected localities, and to see that everything necessary was done to prevent the spread of this malady.

EDINBURGH.—**HEALTH OF THE CITY.**—For the week ending with Saturday, the 2nd inst., the mortality in Edinburgh was 28, and the death-rate 20 per 1,000. There were 11 deaths under 1 year, and 21 above 60, of which 4 were above 80, and 1 above 90 years. Diseases of the chest accounted for at least 50 deaths, and zymotic causes for 4, of which 2 were due to scarlatina and 1 to measles, the intimations of these diseases being respectively 31 and 28.

PRESENTATION TO DR. FRANCIS HENDERSON, OF HELENSBURGH.—At a meeting of the patients and friends of Dr. Francis Henderson, held on the 2nd inst. he was presented with a cheque for £500, a drawing-room timepiece, and a diamond ring for Mrs. Henderson, in recognition of the feelings of regard and esteem in which he had been held in Helensburgh during the past 18 years. The state of his health had necessitated Dr. Henderson's severing his connection with Helensburgh. He has taken up his residence in the West End of Glasgow.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 2nd inst., were at the rate of 28 per 1,000 per annum, against 28 in the preceding week, and 20, 25, and 29 in the corresponding periods of 1881, 1880, and 1879.

THE NEW COUNTY HOSPITAL FOR Ayr.—The annual meeting of the subscribers to the Ayr County Hospital was held on the 4th inst. The report of the Committee of Management showed that the total income for this year had been £811, and £850 last year, and the amount of expenditure this year £886, leaving a deficiency this year of £75. The board of management recommended the appointment of Dr. Chalmers C. Scott as resident house surgeon in the new hospital, and it was agreed to open the hospital on Christmas day. It was intimated that the subscriptions to the new hospital amounted to £6,906, of which only £160 remained to be received, and that up to November the cost of the hospital had been £3,589. It was intimated that twenty persons had furnished wards at their own expense, and others had furnished various appliances, and that Sir Andrew Barclay Walker would give a donation of £500 for the support of the children in the hospital.

PERTH.—**COMBE LECTURES.**—The closing and eighth lecture was delivered in the City Hall, which was crowded in every part, when Dr. Andrew Wilson, the Combe Lecturer, gave an interesting discourse on "On Ventilation, and the Skin and its Work." The present lectures have nightly attracted large audiences, far exceeding any similar auditory which has attended lectures in Perth. At the close, cordial votes of thanks were passed to the Combe Trustees, and to Dr. Wilson.

GLASGOW.—**ASSOCIATION FOR PROVIDING TRAINED NURSES.**—The seventh annual meeting of the Association for Providing Trained Nurses for the West of Scotland was held on the 7th inst., in the Religious Institution Rooms, Sir Archibald Campbell, Bart., of Blythswood, presiding. Mr. Kerr, Secretary, read the annual report, which was of a highly gratifying nature. The adoption was moved by Sir Archibald Campbell, and seconded in a fine speech by Dr. S. J. Moore.

ILLNESS OF PROFESSOR GRAINGER STEWART.—We are glad to state that Professor Stewart, who has been confined to his room for nearly three weeks, suffering from a severe rheumatic cold, is now convalescent, and will soon be in his lecture-room, where his presence has been greatly missed.

THE FELLOWSHIP OF THE EDINBURGH COLLEGE OF SURGEONS.—Of the fourteen gentlemen whose names are proposed for this distinction, only one of them resides in Edinburgh. Six reside in London, five in the provinces, one in Ireland, and one in Africa. What can be the value to these gentlemen of their new title, unless they are anxious to let it be known that they have £25 to spare? One would have thought that the public were sufficiently educated by this time to be able to place the true value on this distinction. This does not appear to be the case, or the demand for it would have ceased.

UNIVERSITY OF EDINBURGH.—We understand that at the last meeting of Senatus two portraits were presented to the University—one of the late Dr. John Muir, presented by his brother and sister, Sir William Muir and Mrs. M'Laren; and the other of the late Charles Murchison, M.D., presented by the Murchison Memorial Committee, who recently founded the Murchison Scholarship in clinical medicine.

THE TYPHOID EPIDEMICS OF GLASGOW.—Last Thursday Dr. E. Duncan read a paper before the Philosophical Society of Glasgow on the clauses in the draft of the Glasgow Police Bill

which have reference to the prevention and mitigation of disease, taking as his premises the two facts—first, that during the prevalence of the excessive milk epidemics which had occurred during the past eight years, although there was an unusually large amount of the typhoid poison circulating in the drains and sewers of Glasgow, there was no extension of the fever along the lines of drainage or into the neighbouring houses; and, secondly, that in many instances the house drains and soil pipes in these neighbouring houses were very defective, and freely permitted of the flow of sewage gases from these soil pipes and house drains containing the typhoid poison into these houses. The obvious conclusion was, that in Glasgow epidemics of typhoid fever did not now arise from the inhalation of sewer gases. On the basis of these facts, he asserted that the cases of typhoid which were so produced must be comparatively few—first, because five weeks must usually elapse after the poisoning of the community began before the sanitary authority could become acquainted with its cause; secondly, because the statistics of other towns in which the clauses proposed in the Glasgow Police Bill were enforced, did not, on the whole, give any evidence of progressive improvement in the death-rate from this disease; thirdly, because the bulk of the cases of typhoid were not propagated within the jurisdiction of the city authorities, but came from without; and, lastly, because typhoid fever was not an infectious disease in a public sense, and might safely be treated at home without the slightest fear of its spreading, if the excretion was properly disinfected. On those grounds, he held that neither compulsory notification nor the milk clauses in question would materially diminish the prevalence of typhoid fever in Glasgow. It was from insanitary farm-houses that the typhoid epidemic of Glasgow sprang. He had no doubt but in many of the milk epidemics Glasgow had only reaped what it had sown. The consideration of the paper was adjourned after a partial discussion.

Literature.

MEDICAL AND SURGICAL REPORTS OF THE CITY OF BOSTON HOSPITAL. (a)

THE first paper in this series is of considerable interest, the subject being one upon which there is much information yet to be obtained. Dr. S. G. Webber has carefully studied the normal and pathological histology of the spinal cord, and gives the result of his labours, comparing it with the experience of others; he also adds some good drawings taken with the camera lucida from sections prepared by himself.

The structure of the neuroglia of the cord is most carefully and accurately described, as Dr. Webber says "it" is one of the most important studies in the normal histology of the cord, in order to obtain a correct basis for the study of pathological processes.

Describing Deiter's cells in the neuroglia, Dr. Webber has frequently seen nucleoli in these cells, and in many instances with a high power he has seen two or three fine fibres radiating from the nucleolus.

He has been unable to detect any sheath covering the nerve-fibres, which seemed to him to be closely and immediately enveloped by the neuroglia, and he has satisfied himself of the existence of a peri-vascular lymphatic sheath surrounding the blood-vessels.

Dr. Webber describes the neuroglia as consisting of nuclei, fibres, and branched cells. In disease the nuclei are increased in number, and in the more advanced stages of the degeneration enlarged in size. The fibrous tissue is increased; in chronic disease the fibres are much finer than normal; in

acute degeneration the fibres are twice as large as normal. The cells are increased in size and number. Some of the cells have no processes, others are large, star-shaped bodies with many processes (spider cells). In sclerosis these spider cells are often united by one or two of their processes with the sheaths of the blood-vessels, which Dr. Webber considers confirms the view that they are lymph canals.

In diseases of the neuroglia he has been able to find only fibres, nuclei, and cells, and has not been able to demonstrate the foundation substance; neither has he seen the excrecences arising from the fibres, nor anything resembling fibres composed of fibrillae, all of which structures have been described by Frommann. With regard to the changes in the proper nervous elements in disease, both the medullary sheath and the axis cylinder may be affected, or either alone.

In acute myelitis the medullary sheath is enlarged, and the axis cylinder hypertrophied. In extreme cases the nerve fibres may entirely disappear; generally, many of the axis cylinders persist. If the nervous elements are chiefly affected, the axis cylinder quickly disappears; otherwise the axis cylinder persists almost indefinitely. The nerve cells in chronic disease contain an increase in the amount of deep yellow pigment, the processes are shortened and some entirely disappear, the cell diminishes in volume, loses its irregular outline, and becomes globular.

Dr. Webber adds a caution in studying the changes in the cells in disease. He says: "It must be remembered that the cells vary much in shape and size in different regions, and even in the same region; yet those in the same region closely resemble each other. In judging as to disease of the cells this must be considered; thus, in the anterior cornua, a number of globular cells with only one or two processes, would show disease; but in Clark's columns this is the normal character of the cells; also in the anterior cornua a fusiform cell with only two processes is rarely seen, and many of these, especially if small, would show disease; but in the tractus intermedio-lateralis, and in the posterior columns, this is the more frequent shape, and the prevailing size is small."

Cavities or vacuoles are found within cells either singly or in groups; the septa between the cavities may break down, forming one larger cavity. The central canal is frequently obliterated by an increase of nuclei or cells.

In conclusion Dr. Webber describes the manner in which these changes in the elementary structures of the spinal cord are combined to produce the various forms of disease.

Dr. Ellery Stedman gives the record of the cases of typhoid fever treated in the hospital between 1st January, 1871, and 1st January, 1881, and adds a few practical observations:—There were admitted, 1,036; of whom died, 186; a percentage of mortality, 17.9-10. There were admitted 12 patients over 50 years old, of whom 4 died; one was 60 years old.

Dr. Stedman, having given the details of 23 cases completed by autopsy, makes a few notes of the experience of 192 cases under his own care during the last 10 years. He finds that as many patients came from the newly-annexed and half-rural districts as from the old central and crowded parts of the town.

Contagion, he considers, is not a cause of the fever. It resembles contagious disorders unusually, exempting the patient from subsequent attacks, and this is one reason, he believes, why people over 40 are less liable to this fever, so many having had it once, even, perhaps, so mildly that it was not recognised, the ambulatory form being more common than is supposed.

Dr. Stedman has been surprised at the numbers of cases he has seen, inside and outside the hospital, where diarrhoea as a symptom never appeared. The highest pulse recorded in a case of recovery was 160 on the 14th day. The highest temperature was 107 deg. on the 11th day. The writer has found the disease much more dangerous in an intellectual patient. The last quarter of the year, though furnishing most fever patients, is not the fatal season; he notices that in the hotter months of July and August, the cases, though fewer, are shorter and more intractable.

Dr. Stedman's experience teaches him that the course of a relapse is milder, shorter, and more tractable than the original malady. He says: "Before last year I had never seen a death from relapse of typhoid fever." The pulse he finds to be the most reliable guide to the condition of the patient in this affection; he has seen no patient die whose

(a) "Medical and Surgical Reports of the City of Boston Hospital." Third Series. Edited by David W. Cheever, M.D.; Oliver F. Wadsworth, M.D.; and A. L. Mason, M.D. Published by the Trustees. 1882. Pp. 200.

pulse has not reached 120 twenty-four or more hours before death, though many recover whose pulse has risen above 120.

Among the surgical cases under the care of David W. Cheever, M.D., are five cases of bronchocele, in four of which he successfully performed excision of the tumour; the fifth case, treated by setons, terminated fatally. Dr. Cheever does not seem to consider that there is as much danger in excision of the tumour in goitre, as has been stated by most authors, who advise the operation to be performed only in very extreme cases, where life is in immediate danger; the danger being due to the great vascularity of the tumour, removal of which is generally attended by such profuse hæmorrhage as necessarily to endanger the patient's life, and perhaps to prevent the completion of the operation.

In the four cases in which Dr. Cheever removed the tumour there appear to have been no urgent symptoms caused by the presence of the tumours (in one case, indeed, it was removed from a young lady simply for the purpose of improving her personal appearance), and he seems to have experienced no trouble from hæmorrhage during the operation. In one of the cases Dr. Cheever met with the peculiarity which has been described in a French monograph on bronchocele: "When the tumour has attained sufficient size to engage itself under and lift the sterno-mastoid muscle in its lateral growth, the apex of the lateral lobe insinuates itself between the internal jugular vein and the carotid artery. The vein is lifted forward on the tumour, and will be found, during the operation, in contact with and just under the anterior edge of the sterno-mastoid muscle, in an unusual and unexpected place, and presenting some danger of being wounded. The carotid artery, and with and behind it the pneumogastric nerve, will be found entirely beneath the tumour. Although these cases were operated upon with so little difficulty and terminated so successfully, Dr. Cheever remarks: "If similar cases present themselves again I should urge the trial of at least six months' medication with iodide of iron and iodide of potash."

"Cancer of the Tonsil: Removal of the Tumour by External Excision." Under the above heading Dr. Cheever describes the second operation by this method for this rare disease performed by him.

The first operation was undertaken in 1869, and he was then under the impression that the operation was original. He now finds in the "Jahresbericht des gesammten Medicin" for 1869 that Dr. Hueter says he saw Von Langenbeck operate externally, and by sawing the jaw, in 1865; and that he himself performed a similar operation the same year. Both were cases of sarcoma; Langenbeck's recovered; Hueter's died.

Ollier's Operation, as performed by Dr. Cheever, for the Removal of a Naso-pharyngeal Polypus.—Starting at the root of the nose, over the frontal bone, mid-way between the eyes, an incision was made downward and outward by the side of the nose to the alar cartilage. A similar cut was made on the other side, both incisions reaching the bone. The blade of a small straight saw was then laid flat on the forehead, and the nasal bones and vomer were sawn through down to the alar cartilages. The nose was now easily upset and turned down upon the mouth. Next the vomer was broken and bent by the finger over to the left side, and the inferior turbinated bone was cut away with bone forceps. There was now room enough in the left side of the nares to reach the tumour with the finger. It was found to be attached by a broad root to the body of the sphenoid and to the right palate bone. It was scraped off the bones by the periosteum scraper. Aided by the finger in the mouth it was removed whole, and proved to be an oval fibroid, as large as a pullet's egg. The nose was now replaced, and the nasal bones were wired to the face by two wire sutures, the skin being carefully readjusted with one wire and seven silk sutures. It fitted perfectly. Perfect recovery.

Dr. Gay, alluding to the theory of the local origin of cancer, and the indication it gives for early and thorough extirpation, does not think that there is a period of time, after a diagnosis is possible, when a cancer can be removed with a fair prospect that it will never return; but still advises operation for their removal as making the remainder of life more endurable. He considers that, according to the theory of the local origin of cancer, more extensive and thorough operations for the extirpation of malignant diseases are indicated than have heretofore been customary.

In the removal of breast cancer, for example, not only is the affected gland to be excised with the overlying structures, but the axilla should also be cleared of everything except blood-vessels and nerves, whether the glands are enlarged or not, for they are frequently diseased before they can be detected by external examination. He says our most satisfactory cases have been those in which, by careful dissection, the axillary vessels and nerves, the ribs, and the intercostal muscles have been freely exposed, and also a portion of the pectoralis major, under which glands are liable to remain concealed from the operator, has been cut away.

Considering the volume as a whole, the papers would lead one to believe the surgical department to be in advance of the medical at the City of Boston Hospital, and although containing a few subjects of interest, the book would not be likely to meet with many readers on this side of the Atlantic. The papers contain the minute details of too many uninteresting cases, which increase the size without adding to the value of the work.

THE PRACTICE OF COMMERCIAL ORGANIC ANALYSIS. (a)

THE first volume of this work, which was reviewed in the *Medical Press* at the time that it appeared, seems to have met with so favourable a reception from the public that the author has been induced to follow it up with a further instalment, and promises a third. Upon animal products he says: "I have postponed their consideration till a demand shall arise for an additional volume, or a second edition of those already published." We sincerely hope that the writer will follow out the first-named intention and make his work as complete as he possibly can. We have no work of importance running upon the same lines as Mr. Allen's book, as it is perfectly distinct in character to such works as Fresenius' "Qualitative" or "Quantitative Analysis."

His second volume deals with hydrocarbons, fixed oils and fats, starches and their isomers, alkaloids, sugars, and contains a good index (all-important to a work of this class). When we state that the last volume extends to over 500 pages, we see that it is something more than the practical notes of an expert, and that the subjects have been treated at least in an elaborate form.

As we have very little to say disparagingly of this work, we may at once get that little off our mind by objecting to two points: 1st. In a work of a purely technical and practical nature we cannot see any use in the attempt to arrange it according to a scientific classification. It might have, perhaps, facilitated the author in his writing the work. But as reviewers, we can only look upon the utility of such an arrangement to the reader, or rather, we should say, to the practical analyst who intends to make use of it. For instance, whilst glycerine would, from its technical and commercial analog, be naturally better considered in connection with fatty acids and soap, which occurs in the second volume, we have to look for it in the first volume, amongst the alcohols, because it is scientifically considered as the triatomic glyceryl alcohol. Dextrine is found in vol. i., whilst starches are found in vol. ii. By-the-by, illustrations might have been introduced with great advantage when dealing with the starches. This arrangement also frequently leads to a strained classification—for instance, although some pages are devoted to the estimation of sugar in diabetic urine, the rest of the important normal and abnormal ingredients, such as urea, albumen, &c., are ignored, we presume because there is no convenient place for them. The general analysis of urine would not, of course, come under sugars. Or again, in giving the process for determining the original gravity of worts, instead of considering it under the head of sugar, would it not come better under the description of estimating alcohol, for it is essentially nothing but such a process, or if not, under an article upon beer, vol. i.

The volume under review contains very elaborate articles upon turpentine and balsams. Anthracene, nitrobenzene, and benzene are also important monographs from a commercial and scientific aspect. There is a careful and exhaustive article upon petroleum-testing. It contains a description of the close testing for the flashing point of petroleum oils, an important

THE

"Bradshawe" Lecture

ON

SOME RARE AND NEW DISEASES.

Delivered at the Royal College of Surgeons of England on December 13th, 1882.

By SIR JAMES PAGET, F.R.S.

MR. PRESIDENT AND GENTLEMEN,—It is my first duty, in delivering the first Bradshawe Lecture in our College, to offer a tribute of respectful thanks to the generous lady by whom it was founded, the widow of Mr. William Wood Bradshawe, a Fellow of this College, who practised at Andover and at Reading, and died in 1866. He was a home-loving and studious man, who diligently cultivated his mind in both literature and science, and his widow, who survived him fourteen years, being desirous to testify her gratitude for the happiness which she owed to him, bequeathed a thousand pounds to this College, and as much to the Royal College of Physicians, on the condition that each should institute a lecture, to be given annually, and to bear his name. She desired that the lecture should be on some subject connected with medicine or surgery, and that the choice of the lecturer should rest with the President of each College for the time being. She made no stringent regulations, and seems to have wished only to maintain her husband's name in good repute by associating it with the advancement of the science which he loved.

In my endeavour to fulfil her exemplary wish, I have chosen the subject of "Some Rare and New Diseases." I hope to be able, in speaking of them, to illustrate a part of the natural history of disease which I think is too little studied—that part, namely, which relates to the variations and the combinations of diseases in hereditary transmission. Besides, both in the choice of its subject and in the whole enterprise of giving this lecture, I have looked for an opportunity of promoting pathology by promoting pathological

museums, a motive which I am sure will be pardoned though I am conscious of its being in some measure personal, for I have spent so much time and thought in museums, that I feel as if, in their greater utility, I should myself become more useful.

Now, first, respecting rare diseases, there may seem no want of opportunities of studying them. Our journals and the proceedings of our societies are full of the records of rare cases; many collections of such cases have been published, and there are many rare specimens in every museum. All these have that kind of attraction which belongs to everything that excites our wonder, but we too seldom let the wonder have its proper consequences; we too seldom let it provoke our curiosity so far as to make us search for the meaning and reason of the rarity. There is a question we should often ask ourselves—Why is any disease rare? At least, why is any rare which does not depend on some accident or some rarely occurring extreme cause? I shall try to suggest answers which may be, in some instances, sufficient; but I fear that, in more instances, if I can be useful at all, it can only be by suggesting how answers may be found.

First, there is a difference, though it may seem only a verbal one, between rare cases and rare diseases. A case may be called rare when, though it is evidently one of a common disease, it differs from the usual type or standard of that disease in some one or two features. Thus it is a rare case when a common disease is found in an unusual place; as an epithelial cancer on the upper lip, or this fatty tumour on a finger: or in unusual quantity, as in this large cartilaginous tumour on a femur; or again, a case may be rare in respect of the time of its occurrence. For instance, I have lately seen cancer of the rectum ending fatally in a lad of eighteen, and scrofulous abscess in a man of eighty; and many of us must have seen instances, though they are rare (and these are very important in the history of diseases), in which manifestations of syphilitic inheritance, usually evident in infancy, have not appeared till the time of youth or even of adult age; or cases may be very rare in respect of accidental complications or of the absence of some usual symptom. But of all these and other rare cases the number and variety are so great that it would be impossible to deal generally with them, except as with mere story-telling. It would be very useful if someone would collect

hundreds or thousands of them, and arrange them, even though it were only under such headings as I have just indicated. But even as they are singly and in disorder, let me say that we ought not to set them aside with idle thoughts or idle words about "curiosities" or "chances." Not one of them is without a meaning; not one but might be the beginning of excellent knowledge, if only we could answer the question, Why is this rare? or, being rare, why did it in this instance happen?

But, because of their number and variety, I must pass by rare cases and will speak only of some rare diseases—that is, of some diseases which are rarely seen, and yet occur in a sufficient number of cases, and with sufficient uniformity, and sufficient difference from other diseases, to permit of their being described in general terms, and to justify their being called by distinctive names. And of these again, for they are numerous and various, I shall select that group which seems most attractive; the group of those, namely, of which there seems reason enough for believing—First, that they were, lately, new diseases and have become more frequent; and, secondly, that they are due mainly to morbid conditions changing and combining in transmission from parents to offspring. I say due mainly. It is certain that changes in the external conditions of our life have influence on even those morbid conditions which are most personal; but this influence is very hard or impossible to trace in the cases which I have in mind, and it may to-day be neglected though not forgotten. For, in all those cases, the personal factors and those of which alone I have to speak are more potent than the conditional, the inner than the outer. We call these diseases constitutional, diathetic, or by similar names; but the chief fact in them is that they, or the necessary previous states or predispositions to them, are inborn and inbred.

Let me first show that there is reason enough for believing that some rare diseases of this kind were recently—say within the last century—new; and that more recently, though still rare, they have become more frequent. There is, I know, a general unwillingness among pathologists to admit that there are new diseases of this kind; and this unwillingness is often just, for many diseases that may seem new have probably existed long and been overlooked; they may be new to knowledge, but not new in fact. Bright's disease and Addison's disease were new in the sense of having first been well observed and described by those whose names they bear; but no one would venture to say of diseases so difficult to detect, as these used to be, that they did not exist long before they were well observed. We could as well believe that embolism never occurred till just before it was found out, or that right-side hemiplegia used not to be associated with aphasia. These things were old before they seemed to be new; but how long they had existed neither records nor museums can tell. It would be, indeed, very interesting if we could tell the time and manner of first appearing in the case of many diseases which are now common; but it is scarcely ever possible. And yet, if you will allow me a digression, let me show what in some instances museums may supply, and what I hope they will in the future supply much more largely. Here are specimens of typhoid ulcers of the intestines preserved by Hunter. Few things have been more important in the knowledge of fevers than the clear proofs of the distinction between typhus and typhoid given by Sir William Jenner in 1850. It was one of the best life-saving discoveries of this century; before it both diseases were at least partially misunderstood, and neither was so well treated as now. Since the distinction between them was discovered it has been possible to trace in old recorded cases probable instances of both; but there is nowhere so clear evidence of the occurrence of typhoid a century or more ago as is given in these specimens of Hunter's preserved without name or history; not unobserved, and yet not in any fair sense understood. Now in this, as in many things, Hunter set us a good example. He did not think those things unimportant which he did not understand. He was a thorough naturalist, and kept specimens of everything in his field of study which, though not yet, might become useful.

But, however much of what seems to be new we may justly ascribe to our previous oversight of what was old, there yet seems to be evidence enough that new diseases are in progress of evolution, and that, as I have said, some of the rare diseases of which I have to speak are the earliest instances of the new. Good evidence of this kind is to be

found, I believe, in the peculiar joint disease discovered by M. Charcot in association with locomotor ataxy, and in the disease of bones to which I have given the name of *osteitis deformans*. Neither of these, I believe, was described till within the last few years. They may have been overlooked, but to believe this we must believe what is very improbable. We must believe that all the most acute and observant practitioners before our time overlooked, not merely obscure and transient diseases, difficult to study, but cases which lasted many years and gave constant great distress, and were manifested in signs so plain that they could be recognised in the shape and gait, in the posture and whole aspect of the patients, in strangely large heads and curved limbs. And, further, we must believe that the morbid anatomists before ourselves overlooked changes of structure of the largest, most obvious, and most striking kind. It is, surely, very unlikely that they who studied and recorded such cases as those of extreme rickets and *mollities ossium*, and even called it *rachitis adultorum*, should have left unnoticed the cases of these two equally and somewhat similarly disfiguring and damaging diseases. This great improbability is strengthened by that which I believe to be a fact—that we have none but recently collected specimens of either of these diseases in our museums; not even among the crowds of bones and joints collected by our predecessors.

In twenty-six years I have seen twelve well-marked cases of the *osteitis deformans*, and about as many in which it was only partially evident. In the last six of these years I have seen seven of these cases, and others have been published, and yet I cannot find evidence that the disease was ever seen by any of those who had practice like my own; Brodie and Stanley, who saw as many cases of diseased bones as any surgeons of the last generation, had seen no case but that which I showed them more than twenty-five years ago in the patient from whom these specimens were taken. Moreover, I cannot find an old specimen in our museums, or a representation of one in any book of plates, or a description of one in any catalogue. This might not seem very strange in the case of specimens troublesome or expensive to keep, or in such as are said to "show nothing." But these are very striking deviations from health, very plainly to be seen, and dry bones are neither costly nor troublesome to keep. We have large numbers of them collected by Hunter, Howship, Langstaff, Liston, Cooper, Stanley, and others, who collected not merely illustrations of diseases well known to them, but whatever was curious, whether it was understood or not. They would have looked on these bones as gems.

I might repeat this statement in nearly every particular concerning M. Charcot's disease. I believe there is not an old specimen in our museums. There is not one in the Musée Dupuytren; I cannot find a notice or an illustration of one. And yet this disease is now so far from being very rare that Dr. Buzzard has had nine cases under his eye at one time, and several have in recent years been shown in our societies.

Let me adduce one more instance of what I believe to have been new diseases within this century, though the museum evidence is not so strong as in those of which I have been speaking. Many believe, and, I think, quite rightly, that instances of typical gout, such as gained for it the name "*podagra*," have lately become comparatively rare, and that a large number of less acute diseases, regarded as forms of incomplete or suppressed gout, are much more frequent. It may be that some or many of these lesser forms were always as common as they are now, but were overlooked or were not distinguished from other similar ailments. But here is a specimen of the effects of phlebitis of the femoral and external iliac veins, which, with its history, may tell that gouty inflammation of the veins was, fifty years ago, if not a new disease, yet a much rarer one than it is now. Sir Henry Hallford saw as much of gout, I suppose, as any man that ever lived; for he was for many years, during a very luxurious period, in the largest practice among the richest people in this town. He gave an account in 1832 of what he called *phlegmasia dolens* in the male. The disease so-called was common and well-known in women after parturition; so that, to justify his essay as a record of cases hitherto unobserved, it was enough for him to speak of *phlegmasia dolens* as occurring in men. He speaks of it as having been not long before regarded as "immediately occasioned by a deposit of milk"; but that "being tested by a more exact pathology," it was now attributed to "an inflammation of

the veins of the pelvis." And he says, "he was much mistaken if he had not seen three instances of it" in men "within the last few years." He then relates the case of the nobleman from whom, several years afterwards, this specimen was taken by Sir Astley Cooper—an admirable example of phlebitis, which we may be nearly sure was gouty, showing the changes in the blood-clots and in the walls of the veins during many years.

At the present time, phlebitis of this kind in the male can scarcely be called a very rare disease. There are few, I imagine, in large practice who have not seen many more than three cases within the last few years. So, we may believe, I think, that the disease has become more frequent in the last fifty years; and may suspect that not long before Sir Henry Hallford's time it may have been a really new disease. It is hard to believe that it could have been overlooked. Its characters are strongly marked and evident to both eye and touch: it is a very painful, disabling, long-enduring disease, often recurring, sometimes observed in several members of the same family, and commonly leaving the affected limb large, heavy, and clumsy for many years. Could this have been overlooked when similar limbs, in consequence of an allied, though not the same disease, were known and described in women, and while, as it happened, the subject of phlebitis, in its traumatic and pyæmic forms was being very carefully studied? For there was a form of phlebitis much more common in the last century than in this; the phlebitis that occurred after bleeding. Hunter had studied this very carefully, had written on it, and shown it in these specimens; and after him, both this and the phlebitis after amputation were well-known. Especially after the beginning of this century the phlebitis after amputation was thoroughly worked at. It was only three years before the publication of Sir Henry Hallford's essay that Mr. Arnott's renowned paper on inflammation of the veins was published in the *Medico-Chirurgical Transactions*. In the same volume are the chief papers by Dr. Robert Lee on phlegmasia dolens; and he describes cases of phlebitis associated with pelvic cancer; but not one spontaneous phlebitis is mentioned by either of them.

Now, I think that in all these facts there is enough, not, indeed to prove, but to justify the belief that we have here examples of diseases which have appeared in this country for the first time within the last century, and which have since become sufficiently frequent, and acquired sufficiently constant and distinctive characters to be described in general terms and called by new names. Let me repeat: these are not diseases hard to be discerned. They are so well-marked, so distressing, so long-enduring, and both during life and after death so large and distinct in all their characters that it seems impossible that, unless they were very much rarer than they are now, they could have been overlooked.

I think it probable that there are other examples of the like kind; but I do not know them, and would rather go on to the second part of my subject—namely, to show the probability, or, at least, to justify the hypothesis, that those diseases are among the instances of the results of morbid conditions, changing and combining in transmission from parents to offspring.

It should hardly be necessary to argue that changes of type in inherited diseases—changes which may be compared with the variations of species or of varieties in natural history—do take place. Yet I venture to think that many of us are prone to think too little of these variations; to regard them as rather unmeaning exceptions, or as the results of some unusual external conditions diverting diseases from their customary course.

It will be better for us if we study, in pathology as in natural history, varieties as much as species; changes as well as more stable forms. Types of disease there are, standard forms, and the tenacity with which they are maintained—some, even, from pre-historic times—in all the varieties of the conditions of our lives is one of the most remarkable facts in all pathology. But they are not unalterable. Types vary in diseases, as in species; even in the diseases which depend least upon external conditions, and most on the qualities which are transmitted by inheritance.

Let me give some reasons why this must be.

1st. An exact likeness is never transmitted by inheritance; neither an exact likeness of either parent, nor an exact composite of both. This is evident enough in features, size,

weight, and all that we can observe in external things. If we could be exactly endoscopic we should observe equal variation within; the same want of exact likeness in liver and lung, and, I venture to say, in blood and lymph and plasma, and whatever goes to make up the whole person, healthy or diseased. The inheritance of likeness in disease, or liability to disease is, indeed, clear evidence of the transmission of likeness in the very minutest structure and composition. But the likeness is never perfect, it may in different persons deviate this way or that; it may vary towards disease or back again towards the healthy type; but it is never perfect, and in successive generations its degree of unlikeness may increase to a great width of difference.

2nd. The certainty and probable extent of this variation must seem the greater if we consider the mingling of diathesis, and of all dispositions and liabilities to diseases in transmission from and through both parents. Consider the difficulty of maintaining the "breed" in any of the varieties of the species domesticated or cultivated by us, in horses or dogs, in pigeons or in seedling plants; the care that both parents should be of the same blood, or the same race, and that their produce should be raised in all due conditions; and then consider how numerous and wide, in spite of all this care, are the defections from the type. With these facts before us we cannot imagine that diseased conditions should often be transmitted singly and unchanged; it is, surely, not likely that disease should be transmitted with more fixed conformity to type than normal compositions are. Hybrids and mongrels must be even more common among diseases than among species and varieties.

3rd. And, in thinking of the variation of diseases by combining or convergence of inherited qualities, we may not limit our thoughts to a single generation. It is reasonable to believe that instances occur of reversion, in which diseases or tendencies to disease may appear after a lapse of many generations. Such, I expect, are some of the cases in which leprosy has been seen, even of late years, in this country in persons never exposed to any of its external causes; and to the like of this we may refer, I think, some of the rare cases which defy all efforts to refer them to any combination of types of disease now prevalent.

Now, I half wish that I could escape from the necessity of testing my doctrine by my facts; but as I have often asked myself, so others may ask, how can the cases of rare disease of which I have been speaking, be explained as the results of morbid conditions changing and combining in transmission from parents to offspring. In the phlebitis we may often trace a variation from the customary type or standard of the very old and heritable disease, gout. In many cases its relations to typical gout are clear. The patients are members of gouty families, and in many of them other signs of gout are evident, either coincidentally with the phlebitis or at other times; it has, in short, all the evidences of being one of the many forms of what is called "incomplete gout." But, for a reason why this variety of gout settles (if I may so speak) in veins, especially in those of the lower extremities, I can only guess at a convergence of inherited dispositions both to a modified form of gout, and to some condition of veins rendering them, among all the structures, the most sensitive to the gouty process. Certainly it is not accident which determines the disease to the veins, for this disease "runs in families." I know of its occurrence in two brothers and three of their cousins; and I have heard Sir Charles Locock tell of four sisters who had phlegmasia dolens and whose father had crural phlebitis.

I am conscious that this is little more than guessing, and for the osteitis I must guess still further; or, rather, let me say that, to the furthest bounds of propriety, I must exercise that use of the imagination which may happily discern a way towards the truth. I imagine, then, that a likeness of the osteitis deforms to several other diseases may indicate a combination, in definite proportions, of transmitted dispositions to those diseases; a combination which has become possible by changes of the type of one or more of them. First, it shows some relationship to mollities ossium and rickets, for, though it is an inflammatory disease, which they are not, yet the softening which permits of the curving of the bones is distinctive, and hardly occurs in any other form of inflammation of bone in middle or latter life. And, again, the relation of the osteitis to rickets and mollities ossium is notably indicated in the porous thickening of the skull, which is found in some instances of them all, and

which is well marked in our specimens of genuine rickets from erroneous diet in young lions and young monkeys. Further, there appears some relation to gout, for some of the cases have known inheritance of gout, and instances are sometimes seen, in typically gouty persons, of a single bone having all the characters of the osteitis, though all the other bones appear healthy. Such a one is this femur, for the opportunity of showing which I am indebted to Mr. Bowlby of St. Bartholomew's. There is a likeness, also, it may be said, to the osteo-arthritis and other forms of rheumatic gout in the remarkable maintenance of good general health during even many years of a painful and crippling inflammatory disease; and, further, there appears some relationship to cancer in the singular frequency with which cancer or sarcoma occurs in the healthy bones or other parts of those who have suffered for many previous years with osteitis deformans.

Thus, I imagine, by inherited dispositions, accumulating and combining or converging in definite proportions, this disease may be produced. I would try to imagine the genealogy of M. Charcot's disease, but that I have too little clinical knowledge of it. I can only suggest a combination of osteo-arthritis with syphilis chiefly localised in some spinal nerve centre; but I believe far better suggestions may be made by those who, suspecting a combination of diseases rather than many radiating from one source, will carefully study the essays of Professor Charcot and Dr. Buzzard's admirable clinical lectures on Diseases of the Nervous System. Besides, I may seem to have guessed already more than enough. Let me, therefore, say that even if my guesses are wrong, my error cannot weaken the probability of the belief that these and rare diseases of like kind are instances of settled varieties of diseases, severally due to variations and convergence of morbid conditions in hereditary transmission. And if this be in any measure true, or even not more than a reasonable hypothesis, then it must be of great importance that we should know much more than we yet do of the variations which, in progress of time, diseases, or certain examples of them, may undergo; of their deviations in a gradually increasing number of instances from typical or standard forms; their acquirement in those instances of other comparatively fixed and long-abiding characters; of the occasional disappearance of old forms of disease, and the evolution of new ones. Such variations in diseases should be studied as Darwin studied the variations of species. Let me be clear in saying as Darwin studied; for in the pursuit of new knowledge he may be a model to all, as he has been to me so far as I could imitate him. He, as I know, would have studied these things, not by deduction, as from a law exactly formulated and from which he could trace the course of every change, but by a most careful collection of facts, facts to be seen in specimens and read in full records, and stored in museums, and by a study as complete for every case as if no law of evolution had ever been discovered.

Let me add that the study of these variations of diseases is not one of mere pathological curiosities. It may be of great practical utility; let me show how, if only that I may provoke some to pursue it vigorously to whom mere pathology is not attractive. We hear much, and often, of the uncertainty of medicines; of disappointments in the use of this or that supposed remedy; and substances which have long been in good repute for the treatment of this or that disease are spoken of with disrespect. It need not be questioned that in many cases the belief in the utility of medicine has been maintained by completely erroneous observations. Such was the belief in the utility of infinitesimally small doses of anything ever yet swallowed. And other beliefs less evidently absurd may have been nearly as ill-founded. But there are many of which this is not to be said. It cannot be doubted that bromide of potassium is often very useful in epilepsy; yet sometimes, as we say, it fails; or that guaiacum is useful in some cases of chronic rheumatic arthritis, and is in others very disappointing; or that arsenic sometimes does and sometimes does not do good in cases of lymphadenoma. I suppose there is not a medicine in the Pharmacopœia which does not sometimes disappoint him who gives it hopefully; not one which is not, therefore, spoken of with contempt or blame, as if it were a responsible agent convicted of default. But here is an unfair imputation. It is not these medicines which are in fault, but ourselves. That which some call the fallacy of therapeutics is generally the fallacy of diagnosis. To state

the facts roughly, we suppose cases to be alike which are really different; and, very naturally, the medicine that does good in some of them is useless in others. For example, in the group of cases which I chiefly have in view, we do not always discern when a disease has varied so far from its usual type that it is no longer amenable to its usual remedies. A better diagnosis must precede a better therapeutics. We need not only the diagnosis between diseases essentially different, but that between the different and varying forms of each of those which we call by a generic name; and beyond this, we need a more exact power of what may be called analytic diagnosis; for there are few simple cases, and in those which are not simple we need to be able to discern all the components, and the proportions in which they are mingled or combined. Better treatment will follow better diagnosis, and better diagnosis will certainly follow a more exact pathology.

Let me illustrate this with an instance which is besides of some interest in the study of the variations of transmissible diseases and of the utility of museums. Questions are often asked as to the changes which syphilis may, in course of time, have undergone; and, especially, whether internal organs were always, as they are now, liable to its attacks. It is hard to answer such questions on the evidence of any existing records; indeed, I might cite the whole history of syphilis as an instance of the insufficiency of records for the tracing of the natural history of diseases. But here is something suggesting what museums may do: a portion of muscle preserved by Hunter, and at least a century old, in which are morbid changes which may be safely referred to syphilitic gumma. Probably similar evidence may be found in other museums, and there are other facts significant of the existence long ago of these internal syphilitic diseases, as well as the improved treatment following better diagnosis. Fifty years ago, at the beginning of my professional studies, it was the custom, as it long had been, to give mercury not only in all recognised syphilitic cases and in most acute inflammations, but in a large number of cases of which one could scarcely say more than that they were all chronic and all obscure. Especially there were many such cases of what we considered chronic inflammation of the eyes, and of the brain and spinal marrow, the liver, and the testicle. To all of these cases it was customary to give mercury, till, as one said, "the mouth was touched," and thus some were cured, and some uncured, and some harmed. The cures were enough to keep the mercury in such good repute that it was given more and more generally; and then the disappointments, as they were called, became too many, and the mercury was blamed, and was almost disused for chronic inflammations. But, meantime, a more exact pathology, a pathology more exact both in its morbid anatomy and in its clinical studies, was discovering the previously unsuspected syphilitic diseases of internal organs; and with this better diagnosis a more judicious use of mercury, and good reason to believe that the chronic and obscure cases which mercury used to cure were those of syphilis overlooked. The case is an exemplary one of the relations between the true pathology and the right treatment of diseases, exemplary not only for encouragement, but for method of study; for the study was both clinical and anatomical, in the living and in the dead, with records and with specimens. Such must be our study of all the cases which I have chosen to speak of—the cases in which diseases deviate from their usual type, or combine in various proportions, after the manner of hybrids and mongrels or new chemical compounds. But there are some rules in study which are especially applicable to these cases.

1. We should very carefully study all cases which are not according to an admitted type. We should study all exceptions to rules; never thinking of them as unmeaning or accidental. Especially, we should never use, in its popular but wrong translation, the expression "exceptio probat regulam;" as if an exception to a rule could be evidence that the rule is right. If we use it, let this be in its real meaning; translating it, as surgeons should, that an exception probes a rule, tests it, searches it—as the Bible says we should "prove all things"—to its very boundary. In this true meaning the words may be an excellent motto for the study of all diseases that deviate from types.

2. We should look out for indications of the existence in the same person of two or more morbid conditions or dispositions such as may be derived from both parents or from

several ancestors. For, as in plants and animals there are hybrids and mongrels, or, as in chemistry, many compounds and mixtures, so are there in diseases. We see them in the multifarious varieties of what we have to call rheumatic gout; in gout crossed with scrofula, or syphilis crossed or mingled with scrofula or with gout. It is often not difficult to discern some of these combinations among our cases, and I know few things in practice more useful than to be able, even in some instances, to adjust our treatment to the proportion of each disease in the compound. But we may be sure that there is much more to be learned in this direction; and it is best to believe that we rarely have to do with a simple and unmixed morbid constitution. There are few worse habits in practice than that of commonly saying of our case "It is all gout," and of another it is all scrofula, or all syphilis. We might as well say of any Englishman that he is all Norman, or all Anglo-Saxon, or all Celt. We may, indeed, sometimes see persons who appear to be as types of races unchanged in many centuries, but in practice we had better study every man as, for better or worse, a composite of many ancestors.

3. We should have for all these cases a much more complete and exact study of all the personal conditions of disease than is now usual. Of course this should include all that can be learned of each patient's family history; though there are few parts of medical inquiry more fallacious than this often is; and at the best it will need, besides, the exactest study of the patient's self. Perhaps the brilliant success which has been achieved by the recent studies of disease-producing organisms or other materials acting on us from without—a success not equalled in any other field of medical inquiry—has made some think too little of those changes within ourselves which occur in such ordinary conditions of life that they may be called spontaneous. Yet these are not less important in the production of diseases, and these must be studied; just as in agriculture soils must be studied as well as seeds. This is true even in respect of those diseases whose essential causes are most evidently external, even of those which are due to specific contagia; their germs or seeds, if I may so speak, will not germinate in an unfit soil. I suppose there is not a day in which most of us do not inhale or come in contact with the germs of some frequent or contagious disease; but they do not germinate in us any more than do the seeds of tropical flowers in our streets or in the fields to which the wind scatters them; we do not offer the fitting soil. And even among those in whom they do germinate, the product varies according to the soil. And the study of this soil, this living soil, is yet more necessary in respect of diseases which come, in part or wholly by inheritance; for it is in each as personal and distinct as any other constituent of personal character, and the study of it must be intimately personal, with an exact analysis of every disposition to disease. The aim of pathologists in this direction should be for knowledge like that of the keen family practitioner, who, as he says, knows the constitution of every member of a family.

All this is equivalent to saying that these variations in diseases must be studied both in practice and in scientific pathology. It is hopeless that either a practitioner who thinks lightly of pathology, or a pathologist who thinks lightly of observant practice, should do more in the study of these questions than attain to that measure of partial truth which is often as deceptive as error. Each must be tested by the other. The living and the dead must be alike and equally studied; and the dead must be studied in exact observations, with accurate records, and especially with museums.

I need not dwell on the value of good records, good descriptions, and good photographs, or other representations of diseases; but they never have been and, probably, never will be, enough. We need, with them, museums in which changes of structure may be preserved for repeated and revising study and comparison. For instance, in regard to the group of diseases of which I have been speaking, we ought to have in our museums specimens in which we might study all the gradations of change of structure from type to type, all the changes due to mingling of forms, all varieties of diseases, all hybrid forms. We need to be able to study all these things, as the naturalist or the comparative anatomist needs his specimens; not only for teaching what is already known, but for continued re-examination and continued additions to his own knowledge.

And for complete study we must have large museums showing the coarse naked-eye characters of diseased structures. I

am sure no one will think me likely to depreciate the microscope; it has added, and will continue to add, more than can be told to our knowledge; but it has not diminished the value of other evidence; and in pathological anatomy, as in all our sciences, there are many instances in which the naked eye sees facts with more meaning than the microscopic one can.

This is especially true in the case of morbid structures resulting from nearly allied diseases, and therefore especially true for those of which I wish to urge the study. In morbid structures as in species the nearer the alliance the less are the differences to be found in minute structures, and the more must we depend for distinctions on the study of visible shapes, and sizes, and constructions. I suppose that we could not with the microscope distinguish the human skeleton from that of the monkey; certainly, we could not distinguish one skull from another in all those varieties of national form which are collected in our museum. And so it is in many instances of morbid bone formation. I doubt whether microscopic examination could detect characteristic differences in each of this group of specimens. With the naked eye it is sure that this is a syphilitic node on a tibia, and this a growth beneath a chronic ulcer over the shin, and this a pedicled exostosis, or ossified cartilaginous outgrowth from the shaft of a long bone, and this an instance of osteo-arthritis, and this a portion of the skeleton of an osteo-sarcoma or osteoid cancer.

Moreover, it is to be observed that in morbid structures, as in those that are natural, in the same proportion as the aggregated elements of embryonic structures acquire their complete and final form, so do the bodies composed of them acquire distinctive shapes and methods of construction plain to the unaided senses. The ova of many species may seem alike both in outer shape and in their component elemental structures. But in proportion as these structures are differentiated, and developed into their higher and abiding forms, as into nerve fibre, and muscular fibre, and the rest, so the larger characters of even the nearly allied species—the characters of shape, and size, and appropriate construction of the whole body, and of each part of it—become more and more different; and these constitute the real distinctive characters of each species.

And so it is in morbid products. The acquirement of distinctive shapes and methods of construction coincides with the development of elemental forms. For example, in these sarcomata are only the lowest elemental structures, round cells, spindle cells, and shapeless plasma; and the masses thus combined are shapeless, featureless, decisive by negation. But in these fatty, and fibrous, and cartilaginous, and bony tumours, in which the elemental structures have advanced to higher forms, the masses which they severally compose are almost as characteristic and distinct in visible shape and construction as are the several normal organs of the body.

In every case, then, both the largest and the smallest characters should be studied. The naked eye can discern one set of facts, the aided eye another; both are essential to complete knowledge; no one should be content with either, for neither is alone sufficient. So we must have large specimens as well as small ones, and certainly large ones for the study of the gradual variations of diseases as they deviate from typical forms, and become variously mingled.

And now, as I come near to my term of time, let me, as is customary in certain other places, conclude with an earnest appeal to your liberality. We want liberal contributions, not of money, but of specimens to our museum. We want specimens of many kinds; of course we want whatever is rare, but not these alone; we want some to complete our series of typical specimens; and, to keep to the chief subject of my lecture, we want the opportunity of choosing among many of what are called bad "specimens." We are all too ready to collect what are called good specimens as being well-marked instances of the standard characters of diseases, and to put aside as "bad" those which deviate from those characters, just as, clinically, we speak of good and bad cases of a disease. Of course, good specimens, typical specimens must be at hand for the teaching of pupils who have to study illustrations of the accepted descriptions of diseases; but it is among bad specimens, even as it may be among exceptional cases, that those who are past pupillage, though they have not ceased to be students, may study the variations of disease. I ask the more boldly for contributions to the pathological collection because of its present satisfactory condition and the activity of work in it. You will soon see it in the repaired and renovated building. Looking at the number and value of the specimens and the

wide range of pathology which they illustrate; looking at the interest of the history of our science which is told in many of them; at the memorials of Hunter and Matthew Baillie, of Astley Cooper, Liston, Howship, Lawrence, Hammick, Fergusson, Hilton and many more; looking forward to what the museum will tell of the researches and skill of those who are still with us, and among whose names I venture to feel sure, Mr. President, that none will take precedence of your own, while men study the specimens with which your skill and just audacity in operating have enriched the series of diseases of the ovaries and uterus: looking at all these things, and then at the perfect order and condition in which the specimens are preserved, I feel that the collection is one which all we members of the College may feel personal pride in calling our own, and should feel a personal duty to enrich. And its utility is being constantly more appreciated. I have been often made happy by the contrast which I have seen while working at the new edition of the catalogue. While I was writing the last edition between thirty and forty years ago, scarcely a student ever entered the museum. Hour after hour I sat alone; I seemed to be working for no one but myself, or for nothing but the general propriety that a museum ought to have a catalogue, though no one might ever care to study with it. Now, and for some time past, a day rarely passes without many pupils and others being at work in every part of the museum.

All this is good; but much more is to be done. Our museum should be, even more than it is, the centre in which all pathologists may find help in searches after that which is not yet known; in such searches, for example, as may lead to a complete knowledge of the variations of diseases. For many years, even from the beginning, the anatomical and physiological departments of our museum have been not only a noble collection of specimens, but, through the renown and learning of its conservators, a great centre of teaching. Scientific men, especially comparative anatomists and anthropologists, have known that here, if anywhere, they could find whatever help a museum and a master in those sciences could give. A fortnight ago the President of the Royal Society, presenting one of the royal medals to Professor Flower, said: "Professor Flower has been for more than twenty years conservator of the museum of the Royal College of Surgeons; and it is very largely due to his incessant and well-directed labours that the museum at present contains the most complete, the best ordered, and the most accessible collection of materials for the study of vertebrate structures extant."

It is not for me to praise the pathological collection with similar words. But great as may have been its utility hitherto, we may be confident that it will henceforth be more useful than ever. In the vast increase of the biological sciences it became impossible that one man should be nearly complete in the knowledge of both natural and pathological anatomy. I say impossible. I believe there is not such a one living; if there could have been one it might have been Mr. Flower. Now, we may hope as labours as "incessant and well-directed" as his will be devoted specially to the pathological collection.

It is known to many of you that Sir Erasmus Wilson, in his usual liberality, gave the College £5,000, of which the interest should be spent in the promotion of pathology; and he agreed that this would best be done by helping to the appointment of a curator of the pathological department of the museum; and we have an admirable one. Mr. Eve is a worthy colleague and helper of Mr. Flower, excellent like him not only in knowledge, but in that which is even more rare, the love of museums, and of all that belongs to their maintenance and illustration, even to the making of catalogues. In all these good qualities he has distinguished himself at St. Bartholomew's. I believe that we may rely on him for making so good use of the museum, and of all that can be brought to it, that the College shall be the chief centre of pathology, even to the furthest point at which it can be studied in specimens of diseased structures. I beg your help that he may be so; and if I shall have helped to-day to this good result, the first Bradshawe lecture in our College will have well fulfilled the purpose of its founder.

DR. SPIERS, of Cleator Moor, who, in September last, jumped into the river Eden and succeeded in rescuing a drowning child, has been presented with an honorary bronze medal awarded by the Royal Humane Society.

RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. Eng., M.S. Lond.
Surgeon to the London Hospital.

(Continued from page 500.)

PART II.—Reported Cases of Recovery—Treatment—Conclusion.

THE reported cases of recovery, after rupture of the urinary bladder with which I am acquainted are 27 in number, and may be arranged as follows:—

1. *Partial or sub-peritoneal ruptures*; one case, under Mr. Keal.

2. *Extra-peritoneal ruptures*.

(a) *Ruptures into the vagina*; three cases, under Wilkinson, Earle, (*) and a friend of Dr. Blundell's, (b) respectively.

(b) *Ruptures into the rectum*; two cases, under Ward and Call, respectively.

(c) *Perforations by splinters of bone*; four cases, under Eve, Astier, Townsend, and Thompson, respectively.

(d) *Ruptures into the perivesical connective tissue*; nine cases, under Syme, Porter, Walker, Padley, Rose, Max Bartels, Berner, Jenmaire, and Brown, respectively. To these I may add a case which came under my own observation.

3. *Intra-peritoneal ruptures*; eight cases, reported respectively by Walter, Le Gros Clerk, Thorp, Erskine Mason, McDougall (two cases), Morris, and Chaldecott. These groups will be taken seriatim.

Mr. Keal's (c) case was modestly reported as a "supposed rupture of the inner coats of the bladder without injury to the investing peritoneum." The patient was a man 22 years of age, suffering from stricture after gonorrhoea. He was knocked down one Saturday by a horse, which fell on the lower part of his abdomen. He felt pain soon afterwards in the pubic region, accompanied with a more frequent desire to pass his urine, which he accomplished with no more than the ordinary difficulty. In about eight hours after the injury the difficulty increased, and soon retention became complete. Up to that period there had been no discolouration of the urine. Retention continued till Monday evening, when he passed a moderate quantity, which relieved him from pain; and he slept from ten till two. On awaking he had much pain, with extreme desire to make water. His medical attendant was now, for the first time, sent for, and had to go home for a catheter. On his return, the patient said that he had experienced a sudden "crack," with a sensation of cold pervading the pubic region, at the same time finding relief from distressing pains. Mr. Keal found the patient tolerably easy, with tenderness over the abdomen, and a sense of distension without any circumscribed tumour. Two quarts of bloody urine were drawn off with the catheter with much relief. The patient was submitted to copious bleeding from the arm, leeches to the pubic region, fomentations, saline aperients, calomel and antimony, opiates at bed-time, and catheterism, and made an early and complete recovery. No comment is needed, for the diagnosis may be admitted without inconvenience.

The examples of rupture into the vagina may be dismissed in a few words. In all distended and neglected bladders were ruptured in consequence of the accession of labour and the use of instruments. The rents were in a most favourable situation, and in this class of cases there is nothing to militate against recovery. Doubtless examples might be multiplied on extended inquiry.

It ought to be generally known that the occurrence of rupture of the bladder during labour may fix a charge

(a) *Lancet*, June 27, 1829.

(b) *Lectures, Lancet*, February 23, 1829, p. 677.

(c) *London Medical Gazette*, 1836.

of malpraxis against the medical attendant. Dr. Taylor observes that the medical attendant is expected to know the probability of such an accident occurring, and to guard against it, if necessary, by the frequent use of the catheter. In *Reg. v. Balsoner* (Liverpool Lent Assizes, 1838) a surgeon was tried on a charge of this kind. We now come to the rectal cases.

Dr. Ward's (a) patient was a man of 28, who suffered from retention from stricture for four days at sea. He was suddenly seized with severe pain in the abdomen in the region of the bladder, followed by great prostration. Sloughs of cellular tissue separated from the rectum, so that the hand passed up to the sacrum, and urine came in a stream from the rectum. A catheter was retained in the bladder. The patient recovered. Presumably in this case ulceration occurred at some point behind the stricture of the urethra, and urine was admitted into the connective tissue between the rectum and the bladder, fortunately securing for itself a free opening into the rectum. Dr. J. T. Call's (b) case, reported recently in the *Lancet*, was briefly this: A chimney-sweep, between 50 and 60, the subject of a "small stricture," was suffering from an attack of retention. Whilst the doctor was away fetching a catheter, water came with a great rush through the anus, according to the combined testimony of the patient and his wife. The patient was walking about the room at the time, stripped to his shirt. Dr. Call does not appear to have made a digital examination of the rectum to clear up the case, but assumes that the bladder ruptured into the rectum. Admitting the reliability of the patient's statement, I think that a far more probable explanation would be that the *membranous urethra* gave way into the rectum. Such communications are sometimes met with in cases of stricture, and I recently had a case where an aperture existed just within the external sphincter. In Dr. Call's case the opening closed with remarkable rapidity without further extravasation, and remained closed, notwithstanding the expulsive efforts made by the patient in a subsequent attack of retention.

The cases of Eve, Astier, Townsend, and Thompson, which I find in Max Bartel's list, ought not to be included amongst ruptures of the urinary bladder. Splinters from fractures of the pelvis pierced the bladder. In one case a splinter came from the urethra; in the others the splinters became encrusted with phosphates, and were removed by lithotomy after the lapse of months or years. We now pass to the cases of rupture into the peri-vesical connective tissue.

Syme's case was as follows: The patient, as already stated, was a stout young gentleman of 17. He was endeavouring after dinner to leap a low paling, two feet high, when he fell and struck the lower part of his belly with great force on the points of two upright spars of wood. Immediately he experienced an intense pain, with a feeling as if the bowels had protruded, and his brother remarked that his clothes were distended over his belly. He was able, with support, to walk a few steps to a carriage. He came under the care of Messrs. Joseph and Benjamin Bell. A catheter was introduced, and after drawing off four ounces of bloody urine, was allowed to remain in the bladder. When seen by Mr. Syme a few hours later, there were great pain, distension of the belly, and a sunk anxious look. Twenty leeches and hot fomentations were applied. The catheter was taken out and an opiate prescribed. On the second day the abdominal pains and swelling were increased; there was dulness on percussion below the umbilicus, and more than ordinary resonance above it. The catheter was introduced with the effect of withdrawing a few ounces of bloody urine. Leeches were again applied in the evening, and the opiate repeated. A restless night was passed, and on the third day there was some confusion of ideas, with considerable impatience for a change

of posture. The abdominal swelling had increased, and there was some oedema of the posterior parts from the chest down to the thighs. The catheter twice drew off a quantity of bloody urine. On the fifth day the patient was in much the same state, but the whole trunk was fearfully swollen, and the respiration was performed as if only a small portion of the lungs had room to act. Complete dulness and obscure fluctuation existed below the umbilicus. About a tumblerful of urine had been removed with the catheter. Mr. Syme now made an incision in the linea alba above the pubes, and cut through a thick mass of condensed tissue at this part, giving issue to a very large quantity of urine which continued to flow after the operation. It was found necessary to enlarge the wound on the eighth day, when a cavity was discovered between the integuments and the muscles of the abdomen. Sloughs of cellular tissue separated. On the eighteenth day free counter openings were made in the flanks, and five days later a large slough of areolar tissue was drawn from the wound, and Mr. Syme detected with his finger a rent more than an inch long in the anterior part of the fundus, on the pubal side of the reflection of the peritoneum. A month after the accident the patient began to pass water by the urethra, and at the end of the six weeks was perfectly well.

Porter's (a) patient was a boy of ten, crushed between a rolling cask and a cart. The pelvis was shattered, and the left femur broken just below the trochanter. The bladder was ruptured anteriorly. The patient suffered intense pain in the abdomen, which he would not allow to be touched, and he expressed a great desire to pass water, but could not void a drop. The catheter drew off a very small quantity of urine deeply tinged with blood; it was retained, and sometimes urine flowed through it. After the first twelve hours, the catheter always came out blackened with sulphuretted hydrogen, and this was considered by Mr. Porter to be a fatal symptom. At the end of forty-eight hours, a small abscess pointed at the left side of the navel. An opening made into the abscess gave exit to an immense quantity of foetid pus and urine. The aperture became fistulous, and discharged clear healthy urine for more than three months. The patient made a complete recovery.

Mr. Padley's (b) patient was syphilitic, and the subject of a tight stricture. The stream of water was small, and more effort than formerly was required to pass it. He had a perforating ulcer of the palate. Mr. Padley believes that an ulcer formed on the mucous membrane of the bladder perforated its wall, and admitted a little urine into the areolar tissue in front of the organ. The patient was attacked with rigors, pain, and pyrexia, followed by induration and extensive phlegmonous inflammation of the abdominal wall. Then came suppuration, sloughing of areolar tissue, and profuse discharge. A few days later there was a gush of urine from the wound above the pubes, ultimately leaving a sinus communicating with the bladder. At first, urine was freely discharged from the wound, but gradually diminished in quantity as the opening contracted and the extensive chasms in the soft parts cicatrised. A small sinus was left. Mr. Padley's explanation of the case seems to be the correct one. The alternative explanation is that phlegmonous erysipelas or cellulitis was the primary condition, and that the opening into the bladder was secondary from sloughing. The objection to this view is that there was no apparent cause for the erysipelas or cellulitis in that situation.

I take the cases of Rose, Max Bartels, Berner, and Jeanmaire from Max Bartel's abstracts. Rose's patient was a man of 25, struck in the left groin by a falling tree, and thrown to the ground. Blood came immediately from the urethra. Catheterism failed. At the end of forty eight hours there was a spontaneous flow of

bloody urine from the urethra lasting three weeks. At the end of two and a-half months a fistulous opening formed at a spot corresponding to the junction of the left pubes and ischium. Here all the urine flowed away. For three quarters of a year the patient was bedridden. At the end of fourteen months external urethrotomy was performed. Erysipelas supervened and death ensued. At the autopsy a small round cavity was found between the bladder and the rectum in which the catheter lay. There was a united fracture of the descending ramus of the left os pubis, with displacement inwards. The abstract does not contain a description of the exact position or extent of the injury to the bladder.

(To be continued.)

THE CONDITIONS OF LIFE WHICH INFLUENCE THE PRODUCTION OF INSANITY. (a)

By CHARLES A. MERCIER, M.B. Lond., F.R.C.S.

THE author prefaced his subject with the statement that by the conditions of life was to be understood the totality of the surrounding circumstances in which a human being lives and moves; and that no circumstance was so common or so recondite that it might not have to be taken into consideration in some case of insanity. That while it might appear that to consider the influence which such remote conditions as climate, such a necessary and universal condition as the air respired, or such a recondite condition as the geological nature of the soil, might have upon the production of insanity, would be going so ridiculously far afield for influences as to be a mere trifling with the subject. Yet, when it was remembered that change of climate may produce nostalgia—a very definite form of insanity; when it was remembered that rebreathed air produces phthisis, whose intimate connection with insanity is too notorious for argument; and when it was remembered that the geological character of the soil is considered an efficient cause of the very distinct form of insanity that accompanies cretinism, it would be admitted that there is no one of these conditions whose influence may not have to be considered in some cases of insanity. Common to all conditions of life was the incident of change, and the next point insisted on was the immense importance of taking account of changes in external circumstances considered as change merely, and without reference to whether the change was harmful or the reverse; and seeing that the essence of change is its suddenness, the importance of regarding sudden changes in the conditions of life. Having laid down a basis of reasoning in the physiological properties of nervous tissue, the speaker illustrated the effect of change by the fact that, in little things, a sudden noise causes a start of alarm, while a much louder noise arising gradually is borne with equanimity; that sudden changes in the weather affect powerfully not only bodily health, but the spirits; that a rapid change of locality from town to sea-side and *vice versa* has often so marked an effect upon the health; that the gradual fluctuations of commercial prosperity produced by the slow alternations of good times and bad times cause so small an accession of inmates to our asylums that excellent observers differ as to its existence; whilst the sudden fluctuation caused by a war of invasion causes a sudden increase that is unmistakable. It is in change that we see, if not the sole reason, a contributory reason, why the self-made man, who rises slowly from the ranks, carries his hard-won prosperity with equanimity, while those who are suddenly enriched by a stroke of luck are notorious for their extravagant behaviour, which not seldom develops into actual insanity. We see why the sudden death of a beloved friend is far more shocking than the death after a linger-

ing illness. Those who live a life in which changes are very frequent are said to live an exciting life; and an exciting life is admitted to be one of the efficient causes in the production of insanity. On the other hand, too little change in outward circumstances is as harmful as too much.

Passing from the general consideration of external circumstances to their examination in detail, the speaker maintained that the conditions of a man's life fall naturally into three groups—those which concern his means of livelihood; those which determine the drafts or demands upon the livelihood; and those circumstances in which he spends the leisure time and spare energy which remain when the livelihood is gained and the drafts are all satisfied.

The conditions of life which affect his means of livelihood are three:—The first is the Precariousness, the second the Arduousness, and the third the Complexity, of the means of livelihood. Each of these elements of danger was considered in detail. It was shown how the liability to insanity increases with the increase in the precariousness of the means of subsistence, precariousness being understood to mean not only the liability to failure of the means of livelihood, but also the amount of vicissitude which such a failure would involve. A total failure in this respect would cause a less vicissitude in the life of a day labourer, who lives constantly on the threshold of the workhouse, than a loss which, though far removed from totality, was yet enough to reduce a wealthy man, accustomed to princely surroundings, to a sordid dwelling in the back street of some poor neighbourhood, even though the worst misfortunes of this man leave him in a better position than the wildest hopes of the labourer could aspire to.

The arduousness of the livelihood was also shown to be an important factor in the production of insanity, the maximum of arduousness being one of the most unfavourable conditions. "There are hundreds and thousands of men" (said the speaker) "who know not the meaning of the word 'leisure,' to whom life is one unvarying round of toil, to whom every morrow brings the self-same curse of labour in its early beams. Such men lead a life that is abnormal. The monotony of their occupation forbids the various developments of their different faculties. Just as, when a parasite buries its snout in its victim, and grows to him, all its energies are drafted into the functions of suction and digestion, and, little by little, its limbs wither, its eyes fade away, its locomotor faculties disappear, until nothing remains of the complex organism but a bag of skin containing a stomach and attached to a mouth; so, when a man's whole time and attention are occupied about a single process, the faculties subserving that process become abnormally developed, and all other faculties wither and fade."

The complexity of a man's employment was shown to be important in two ways—first, because it is a measure of his intelligence; and secondly, because a smaller relative departure from health will render a person unfit to carry on a complex employment than will unfit him for carrying on a simple employment. For instance, it requires a lower degree of intelligence to carry on the occupation of a pavior than to carry on that of a watchmaker; and however much the former may bemuddle himself with beer, he will not disqualify himself for his work so long as he is able to lift his rammer and let it fall again; while a trifling dimness of vision or unsteadiness of hand may render the watchmaker wholly unable to carry on the delicate manipulations of his craft.

The influence of each of these factors acting singly was followed by a consideration of the modifications which their influence would suffer by a combination of them in various proportions.

The second group of external circumstances—those which determine the drafts on the store of wealth—were said to be the conditions in which a man was placed as to the number, health, and so forth of his family, and as to his social position, or the degree of comfort and luxury

(a) Abstract of Paper read before the Medico-Psychological Association, Nov. 8, 1882.

in which he lived. The remaining group of external circumstances—those in which the energies are exercised that remain over after the livelihood is secured and the drafts upon it satisfied—were briefly enumerated. They include the social and family conditions considered from a new point of view—the religious influences which are brought to bear upon a person—the political system of which he is an item—the society in which he moves—the character of his recreations and amusements.

In conclusion, while disclaiming any pretension at completeness, the speaker maintained that he had fulfilled his contention that in every case of insanity the external conditions of life, equally with the internal conditions of bodily health, require examination—examination which need not be in every case detailed, but which should in every case be systematically conducted; and he submitted that this examination might be profitably conducted on some such plan as that broadly and generally sketched out in this paper.

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

(Continued from page 502.)

II. *Cases of Extraordinary Origin*, as defined above, are held to be rare, in comparison with those whose origin is synovitis. This group of cases may be sub-divided into those in which the disease begins in one of the structures of the joint, and those in which it commences external to the joint—articular and extra-articular. Cases of articular origin may commence as—1. A deposit of tubercle in synovial membrane; 2. Tubercle in the cartilage; 3. Tubercle in the bone; 4. Ostitis, diffused or circumscribed; 5. Inflammation of the round ligament.

1. *A Deposit of Tubercle in the Synovial Membrane.*—That miliary tubercle may be deposited in the synovial membrane is not denied, that it is frequently deposited there is doubted. Mr. Croft, one of the most prominent supporters of this view of the mode of origin of hip disease, showed to the Pathological Society (Feb. 15th, 1881) two specimens with deposits of tubercle in the synovial membrane, and other examples were shown by other members. It is to be presumed that the tubercles would by irritation cause synovitis, and that disorganisation of the joint would follow. Such a mode of origin of hip disease certainly does occur but rarely. For, it is to be pointed out that morbus coxæ is generally curable by rest, whereas a tuberculous deposit when once formed increases until the tissue or organ it affects is destroyed, and rest does not check its progress. And again, if deposit of tubercle were a frequent cause of hip disease, we should expect to find the joint disease more frequently associated than it is with a similar disease elsewhere.

2. *Deposit of Tubercle in Bone.*—Under this term two conditions may be understood, viz.: a deposit of true miliary tubercle or a caseous degeneration of inflamed area. A deposit of true miliary tubercle in bone, must be extremely rare. Mr. Frederick Treves seems to think it much rarer than in synovial membrane; and Drs. Wilks and Moxon in their work on pathology describe it as a "pathological curiosity." Erichsen relates the case of a child with hip disease, who died of pneumonia, and in which Dr. Wilson Fox found miliary tubercles all over acetabulum and femur. Caseous degeneration of an inflammatory area in bone is probably a more frequent occurrence than the deposit in the same tissues of true tubercle. A good specimen of caseous degeneration in both femur and acetabulum is preserved in the museum of St. Bartholomew's Hospital. (a)

3. *Deposit of Tubercle in Articular Cartilage.*—The facts, opinions, and remarks which apply to deposit of true tubercle in bone or synovial membrane as a cause of joint disease, apply also to the same deposit in cartilage.

The occasional origin of hip disease in such a deposit is not denied.

4. *Ostitis, Diffused or Circumscribed.*—The origin, either constant or casual of morbus coxæ in a primary ostitis, or has been held by the following authorities:—Albur, Rust, Syme, Gant, Annandale, Erichsen, Barwell, Druitt, Bryant, Macnamara, and Pirrie. But it must be remembered that if, after death, the bone is found extensively destroyed; this is no proof that the disease commenced in bone, for the cartilages and synovial membrane in such cases will gradually be found to have disappeared entirely, and so there is no proof that the disease did not commence in either of them. Sir R. Brodie relates an interesting case, in which he believed the disease to have commenced in bone. From his description of it, it might fairly be supposed that the disease had in reality begun in the synovial membrane, were it not for the interesting fact, that in the elbow-joint the bone were exactly in the same state, whereas the cartilages and synovial membrane were free from disease. In this case therefore, the disease, beyond doubt, was of true bony origin.

Mr. Barwell considers that in young children the disease commences in the region of the epiphysal cartilages of the femur or acetabulum, "at which time and in which parts the formative energy is very great, and liable to be exaggerated, and end in inflammation with subsequent ulceration." This condition is illustrated by a preparation in Guy's Hospital Museum, from a patient of Mr. Bryant's, and of which the drawing below was made.

Disease of head and neck of femur from a child aged eight years. Showing disease commencing upon the head and under part of the neck simultaneously and independently. (Guy's Hospital Museum No. 13179s).

Occasionally the disease may begin in the acetabulum. Erichsen considers cases of this sort more common than any others. In Guy's Hospital Museum there is a preparation (a) showing an ulceration of the floor of the acetabulum with the head of the femur quite sound, and in the museum of St. Thomas's Hospital is a similar specimen. (b) With these exceptions I am unacquainted with any post-mortem evidence in support of Mr. Erichsen's view.

(To be continued.)

THE highest annual death rates per 1,000 in the large towns last week, from diseases of the zymotic class, were—From scarlet fever, 1.5 in Blackburn, and 1.8 in Newcastle-upon-Tyne; from measles, 2.0 in Hull, 2.4 in Cardiff, and 5.3 in Sunderland; from whooping cough, 1.6 in Portsmouth, and 2.5 in Leeds; and from "fever," 1.3 in Sunderland, and 1.8 in Liverpool. The 45 deaths from diphtheria included 20 in London, 13 in Glasgow, 3 in Edinburgh, and 3 in Sunderland. Small-pox caused 5 deaths in London, 6 in Newcastle-upon-Tyne, and one both in Wolverhampton and Nottingham.

(a) Preparation, No. 131810.
(b) Preparation, No. 301.

(a) Preparation, No. 627.

Clinical Records.

ST. MARY'S HOSPITAL.

Chronic Suppurative Inflammation of Vesiculæ Seminales—Exhausting Irritability of the Bladder—Cystotomy without Relief—Surgical Kidney—Death.

Under the care of Mr. NORTON.

From Notes by Mr. GILBERT.

PATIENT, æt. 63, had gonorrhœa once, when he was about 17 years old; never had syphilis. He has always been very healthy, and has not suffered from any disease. He first found a difficulty in passing his water four years ago, and went to a medical man, who passed a catheter and relieved him. He then had incontinence of urine, which was relieved by the same medical man injecting lotion into the bladder. He says his urine has been very offensive, and if he drinks any liquid he almost immediately requires to micturate. His testicles are somewhat swollen, which, he says, came on four months ago; and at the lower part of the scrotum there is a suppurating growth, having all the appearance of a gumma.

Patient looks very ill, and is always requiring to pass his water every ten minutes or a quarter of an hour. His urine never comes out in a stream, but dribbles out. After examination by catheter, Mr. Norton stated there was no stricture; and on examination *per anum* found the rectum enormously dilated with hardened feces. Careful examination of the prostatic region discovered an enlargement behind each lobe of the prostate, with a dip between, somewhat resembling to the touch an indurated fissure of the rectum, but not extending into the anus. This turned out to be enlargement of the vesiculæ seminales, with the dip or space between them. Great pain was caused by pressing the finger upon this swelling. The hardened mass of feces was at once removed, but with little relief to the irritability of the bladder.

June 2nd.—Great pain in passing water. Water passed every ten minutes, about two or three tablespoonfuls at a time.

10th.—Continued to pass his water every ten minutes. When the bowels were open he had less pain in passing his water. Just before going to pass water, he suffered a sharp pain in the glans penis.

15th.—Mr. Norton sounded the bladder for stone, but there was none. Mucous membrane of bladder hypertrophied. Patient was under great pain whilst the sound touched the bladder. Appetite good. Very constive; bowels open every third or fourth day.—Tinct. opii, ℥v.; aq. calidæ, ad ʒj. Injunctio pro vesico.

22nd.—The same pain in the glans before micturating, and now he complains of pain after. He had to pass his water every five or six minutes. Bowels open yesterday and to-day. Temp. normal; appetite good. Examined urine and found no oxalates.

23rd.—Mr. Norton ordered pot. bromidi, gr. xxx.; inf. buchu ad ʒij., t.d.s.

It was evident that the patient was becoming exhausted by the continual pain, continued irritability of the bladder, urine not being retained more than five or six, or, at the outside, ten minutes, and the complete absence of sleep. Opium had been given, uva ursi, bicarbonate of potash, hot fomentations over pubes and perinæum, and injections of the bladder, without any relief. Mr. Norton concluded to perform cystotomy.

On the 29th of June the patient was put under the influence of ether, and placed in the position for lithotomy. A grooved staff was passed, and an incision made through the prostate into the bladder, and a soft india-rubber tube introduced to allow the urine to flow away and leave the bladder in rest for a time. A suppository was introduced of morphia (gr. ʒ).

30th.—Patient suffers a great deal of pain. Had very little sleep, and not able to take food.—Inj. morphia hypod., ℥ij., 2.30 a.m. Inj. morphia hypod., ℥iv., 6.18 p.m. Temp., 100°.

July 1st.—Patient had very little sleep and, stated that he suffered most pain in the glans penis. Has been able to take a little chicken. Urine ammoniacal. Temp. normal. Inf. buchu, Oj. during the day.

2nd.—Did not suffer so much pain. What pain there was was in the glans penis, which he continually grasped.

5th.—Patient has been in great pain. Very thirsty, and drinks freely milk, &c. Temp., 103°.

7th.—Patient still suffering great pain. Temp. 103° F.

8th.—Temp. 104° F. Died at 9.30 p.m.

Post-mortem Examination.—On cutting prostatic urethra, abscess cavities in each vesicular seminales are seen, the left more than the right; these have caused considerable swelling around prostate, but gland is not larger than normal.—*Left kidney* reduced to a mere collection of cysts, and has very little trace of proper secreting substance. Some of the cysts contain white cheesy matter, and others greyish-green viscid pus. There is a great thickening of tissues along left ureter. The ureter, also, is greatly thickened; its walls are dilated, and greyish-black in colour. *Right kidney* is considerably enlarged; ureter much dilated. Kidney is studded with several spots of congestion and purulent infiltration, though no definite abscesses have as yet formed. *Bladder* contracted; mucous membrane thickened, opaque, and greyish-black, with small hæmorrhagic patches, coated with tough reddish mucus.

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

THE STRUCTURE OF THE CRYSTALLINE LENS.—Kölliker in 1854 made the statement that the crystalline lens, which was generally believed to be composed of fibres, was in reality made up of tubes, or that at least the fibres had a tubular covering, and that these tubes might be called the lenticular tubes. This opinion has been combatted by numerous subsequent observers: by Babuchin, Ritter, Henle and others. Dr. Severin Robinski, of Berlin, has recently been making fresh investigations into the minute anatomy of the lens, and has published the results arrived at in the "Archiv für Augenheilkunde." From this we learn that hitherto only macerated preparations have been employed by most observers whilst he, on the other hand, has made use of the freshest eyes possible. By this method of use the structures have been investigated before coagulation has taken place. He has had no difficulty in clearly distinguishing the darker walls of the tubes from the clear contents. He has also observed the fluid exude in irregular drops from the ruptured ends of the tubes. Not content with this, he sought for a reagent that would place beyond doubt or cavil the accuracy of his observations. Such a re-agent he found, in a weak solution of nitrate of silver (1 in 800, or even 1 in 1,000), which answered the purpose admirably. He says: "If we take a fresh preparation in which, from want of refractive power, no walls are visible and colour it with the above-named solution of silver, the membranes of the lenticular tubes, like those of other structures, become browned and coloured, and thereby plainly visible to the eye, whilst the contents which are not yet at all coagulated but liquid remain uncoloured, remain perfectly clear." It remains to be seen whether these observations will be confirmed by other inquirers, or whether twenty-eight more years are to elapse before this question is finally settled.

THREE SUCCESSFUL CASES OF LAPAROTOMY.—At the opening meeting of the winter session of the Leipzig Medizinische Gesellschaft, Herr M. Leopold reported three successful cases of laparotomy. The first was a case of castration of a young woman, æt. 22, who had suffered from severe ovarian neuralgia and dysmenorrhœa. The after course of the operation was free from fever; the patient was immediately freed from her pains of years' duration, and is now remarkably well. The second was a case of removal of a myoma uteri together with both ovaries. The indication for removal was serious flooding and pain. After the abdominal cavity had been opened an elastic ligature was placed on the pedicle, above which the tumour was cut away. The ligature was then removed, the stump

drawn together by sutures, and then dropped. No fever. The third case was one in which a blood-cyst, the size of a man's head, was removed from the left kidney together with the kidney itself, by laparotomy. After opening the peritoneum the tumour was withdrawn from the abdominal cavity, it was then punctured and emptied, after which the numerous adhesions were separated and "fixed off." The kidney which was attached was now brought through the wound, and its vessels together with the ureter tied in three parts. To prevent the slipping of the ligature a mushroom-shaped end was left on the stump. Recovery without fever. Herr Tillmanns reported a case similar to No. I. It was that of a girl, *et.* 24, on whom castration was performed for exceedingly violent ovarian neuralgia and dysmenorrhœa. Her pains had lasted for years, and had been so violent that she had meditated suicide. The after course was free from fever, and the patient was restored to perfect health.

ETIOLOGY OF GLANDERS.—In the Berlin Imperial Health Office investigations have been made into the etiology of glanders which have resulted in the discovery of the micro-organism of this disease. The newly discovered organism was subjected to "pure" cultivation for a series of generations, after which the disease was produced in a horse by inoculation with the germ thus cultivated. The investigation was carried out under the direction of Dr. Loeffler and Professor Schütz, and the discovery is of national importance.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

The opening meeting of the Surgical Section of the Academy of Medicine in Ireland was held on Friday evening, Dec. 8th, in the Albert Hall, Royal College of Surgeons.

Mr. BARTON, President of the College, in the Chair,

Mr. STOKES, Sectional Secretary, and Mr. THOMSON, General Secretary, were present.

The PRESIDENT, in opening the proceedings, remarked that the old Surgical Society of Ireland, which for over fifty years held its sessions in that College, had voluntarily laid aside its separate individual existence in order to be foremost in supporting the new Academy as its Surgical Section. While the name of the Society was changed, it would in all important and useful respects remain the same as before, the organisation of which it formed part giving completeness to its work. In effecting the transformation, little change had been made, the Council of the Society being the Council of the Section. A happy selection had been made as Secretary in the person of a gentleman whose interest in the Surgical Society was proved by his many contributions to it. For himself, he was President in virtue of his office as President of the College. Reviewing the history of the Surgical Society on the occasion of the new departure was suggestive of a funeral oration rather than a triumphant wedding-song, which was more appropriate to its union with the Medical, Pathological, and Surgical Societies; and therefore in his inaugural address he preferred instituting a comparison between the system of clinical surgery pursued here and that which obtained in Paris, Berlin, and Vienna. Dublin stood second to no other city in the thoroughness with which the students were trained in the diagnosis and treatment of disease. At the same time little was done to clear up those disputed surgical problems which could be determined only by the powerful logic of accurate statistics. The conditions of the Dublin hospital system favoured completeness of individual work and good clinical teaching, while the results which might be gained from the variety, value, and number of all the cases put together were, for want of unity, lost. This want could be overcome by the new Academy. In Paris the classes went round with the surgeons as in Dublin, and in addition the interns there, corresponding to the

residents here, took private classes, with permission to examine cases, of which there were a great many to illustrate each subject. In Berlin special clinical teaching could be had in almost any branch of surgery, and therefore favoured advance in special directions, though it might well be doubted if the system of speciality produced the best-informed practical surgeon, and gave to the State and the army men able to use skilfully all the resources of their art. In Vienna the same system was carried to a very high degree of perfection. The advantages of the Continental system, with their vast hospitals, were obvious in stimulating original investigation, and facilitating the collection of reliable statistics, and so arriving at sound conclusions as to the result of different modes of treatment or operation. In Dublin there were in proportion to the population quite as many beds available for clinical instruction as in Paris, Berlin, or Vienna. There were fifteen hospitals in Dublin, the average number of beds in each being 130, or nearly 2,000 beds, of which 900 were available for surgical cases and available for clinical instruction, but divided among eleven different hospitals with an average of 87 beds each, and these divided amongst not less than three surgeons, leaving each an average of from 20 to 30 beds. This resulted in thorough and practical instruction, but the experience of each surgeon was limited without co-operation, and thus the Dublin School of Surgery was prevented taking its place in the van of progress. By the new Academy this defect could be met. Here, as in a common centre, might be lodged the records of the cases in all the hospitals, each case under its proper heading, and thus would be formed a most valuable collection of reliable statistics. He hoped the Council would adopt his view and invite contributions.

LIVING SPECIMEN.

Dr. KILGARRIFF exhibited a patient on whom he had performed the operation of trephining on account of an abscess resulting from a fall in the hunting field. The patient was unconscious for two hours after the accident. At the end of a fortnight he was removed to Dublin suffering much from pain over the upper part of the occipital bone on right side, and also much gastric irritability and general debility. Any motion, such as driving, intensified the pain, and caused nausea. On examination a shallow depression, the size of a florin, was found, bound by a well-defined margin at the situation where he complained of the pain. The diagnosis of fracture, with the subsequent formation of an abscess within the cranium, at the seat of the lesion was made. An exploratory incision was made down to the bone, and a small purulent collection was opened into. Subsequently, the operation of trephining was undertaken; and on exploring the bone a small circular opening through the skull, about two lines in diameter, was discovered. Through this opening, situated on the upper part of the occipital bone, some purulent matter oozed. A circular piece of bone was then removed with the trephine to provide free exit for the pus. An abscess cavity, from which almost half-an-ounce of pus welled up, was opened into. The inner surface of the piece of bone removed was deeply eroded. The cavity of the abscess was washed out with a weak solution of carbolic acid. Subsequently, the patient experienced an attack of erysipelas of the head and neck, from which, however, he recovered; and nothing further occurred to interrupt the progress of complete recovery of the patient.

MORBID SPECIMENS.

Messrs. Kendal Franks, H. G. Croly, A. Benson, W. Stokes, Wheeler, V.P., R.C.S.I., and P. S. Abraham exhibited specimens.

PAPERS.

Mr. STOKES (Sectional Secretary), on behalf of Mr. Francis John O'Reilly, Surgeon to the Trun Union Infirmary, exhibited a right kidney, which Mr. O'Reilly had removed by lumbar section from a patient, *et.* 26, in that institution, who suffered from right kidney symptoms and pus in her urine. He read Mr. O'Reilly's communication, which disclosed that the girl was never free from a desire to pass water, so that her sufferings were of a truly agonising character. The quantity of urine passed daily was fairly normal, and the specific gravity ranged from 1015 to 1020. A favourable opinion was thus entertained of the capabilities of the left organ to discharge the increased functions with which it was about to be taxed. The operation was by the vertical lumbar, or post-peritoneal method, and was per-

formed antiseptically. The vessels and ureter were secured by a whipcord ligature. The external wound was closed with interrupted sutures, and antiseptic dressing was applied. The patient suffered from vomiting during the late stages of the operation. The gland weighed eight ounces, and an abscess cavity at its superior extremity contained about two ounces of pus. The vomiting and depression which manifested themselves during the operation, continued, and the girl sank and died forty hours after the operation. About an ounce of urine was drawn off with the catheter previous to death, and did not contain a trace of pus. The kidney was a specimen of primary tubercular disease. A post-mortem examination was not obtained, but the wound was investigated, and found free from blood-clot and perfectly aseptic.

Dr. ABRAHAM (Curator), said there were small tubercles visible below on the external surface of the specimen.

Mr. J. F. KNOTT read a communication on

DISSECTING ANEURISM.

The specimen exhibited was one removed from a body in the dissecting-room of the Royal College of Surgeons. It was described by the student who first noticed it as presenting the appearance of a double-barrelled gun. Examination showed that the simile was just, for two parallel tubes almost exactly equal in shape and dimensions were found enclosed in a common sheath, and separated by a septum which presented but a very slight convexity to one side. More extended search showed a dissecting aneurism of the aortic arch, which had originally engaged the transverse and descending portions, and for which the injection-mass had passed between the middle and external coats, separating these along the whole length of the thoracic and abdominal segments of the vessel. It had also coursed along the whole length of each common iliac artery to their termination. It was remarkable that both the normal and adventitious tubes had received about equal portions of the injection-mass. A portion of the laminated coagulum was found to project into the space between the external and middle coats of the vessel, along which the injection had travelled. This form of arterial aneurism, first noticed by Maunoir, and afterwards fully described by Laennec, in typical cases allows the blood, after tunnelling some distance between the middle and external coats, passes again into the vessel at some distance. Other forms have also been described (a) where the blood merely separates the coats over a greater or less area, and (b) where it perforates the tunica adventitia at some distance, and becomes diffuse. The doctrine of the primary formation of aneurism, and the classification of these tumours into true and false, was next discussed; then that of the organisation of the clot, and of the treatment of aneurisms in general, in which Irish surgery has attained so many triumphs.

Mr. TUFNELL said treatment might prolong life, but in the case of a dissecting aneurism restoration of health was impossible.

The Section then adjourned.

THE YORK MEDICAL SOCIETY.

The ordinary meeting of this society was held on Saturday, December 9, Mr. W. H. JALLAND, F.R.C.S., in the chair.

The President made some remarks on

TWO CASES OF EXCISION OF THE KNEE

treated by him at the York County Hospital. Both patients were shown. The results were satisfactory. In one case the patient was up within a month of the operation.

Mr. JEFFERSON read notes of

A CASE OF PERNICIOUS ANÆMIA.

The patient was 52 years of age. He stated that for six months before admission to the York County Hospital he had suffered from severe epigastric pain, which kept him awake at night, and that for two months he had vomited after meals. When admitted he was feeble, emaciated, anæmic, his expression was indicative of suffering, and he complained of severe pain at the outer border of the left rectus on a level with the umbilicus. There was no tumour or enlargement of any of the organs. His urine was normal. The case was thought to be one of malignant disease. A pill containing morphia, creasote, and nux vomica was ordered, and after ten days vomiting

ceased. Citrate of iron and quinine was then given with cod-liver oil. In fourteen days he gained sixteen pounds, and within a short time an additional stone. He returned to work, and has had no relapse.

Mr. CLIFFORD GILL showed some sections of

CANCER OF BONE.

The patient from whom the diseased bone was taken was an elderly woman who for many years had been insane. A tumour was noticed in the neighbourhood of the sacro-iliac synchondrosis. This, when removed, had attained the size of a Maltese orange. Shortly after the appearance of this tumour, a small scirrhous tumour of the breast was detected. On examination under the microscope, the bony tumour showed the arrangement characteristic of cancer.

Mr. SPENCER read some remarks on

ACUTE RHEUMATISM.

As illustrating the connection between acute rheumatism and erythema multiforme, he took three cases—those of two young women between 16 and 20, and that of a man aged 40. The women were fair-complexioned and anæmic, the man dark and anæmic. In each case there was a period of invasion, and in two sore-throat during that period. In all three the attack followed on a chill; the erythematous rash commenced by distinct papules on the hands and feet, and the urine was turbid, and deposited urates copiously. In one no affection of the joints was noticed. After some allusion to the remarks of Trousseau, Bristowe, Powell, and Thin on this subject, Mr. Spencer referred to a case brought before the society last session by Mr. Jefferson, where the order of symptoms was—firstly, pericarditis; secondly, erythema papulatum; and thirdly, acute rheumatism. He then read the following notes:—A young, delicate girl, 16 years of age, who had for some time suffered from chlorosis, was exposed to wet and cold. Four days afterwards she began to suffer from synovitis of the ankle-joint. The general symptoms were slight, and there was no febrile disturbance. On the following morning, when rising from the sofa, she fell backwards in a fainting condition, and shortly afterwards died. On post-mortem examination, the walls of the heart were found to be thin, the valves normal, and the foramen ovale patulous. A laminated fibrinous mass, which was partially adherent, occupied the apex of the left ventricle, and a quantity of translucent fibrin, possibly of post-mortem origin, extended from the superior vena cava into the right auricle, through the patent foramen into the left auricle, and through the mitral orifice into the left ventricle, which it nearly filled. Mr. Spencer discussed briefly the question of the essential nature of acute rheumatism, referred to the zymotic and chemical theories of its etiology, and finally pointed out its relationship to gout, in which disease a poison or poisons manufactured by perversion of a normal process is known to be the predisposing cause.

We learn with much satisfaction that Mr. MacNamara, Surgeon to the Meath Hospital, Dublin, and representative of the Irish College of Surgeons in the General Medical Council, who has been very seriously ill with erysipelas of the head, is so far recovered as to be able to return to business.

It is claimed by one writer, says a contemporary, that one and one-fourth more money is expended annually in funerals in the United States than the Government expends for public school purposes, and that funerals cost annually more money than the combined gold and silver yield of the country in the year 1880. This does not include the cost of cemetery lots and burial fees.

The French Academy of Sciences was last week the scene of a graceful and well-deserved compliment to one of the ablest of living chemists, in the presentation to M. Dumas of a medal which had been struck specially to commemorate the fiftieth anniversary of his election as one of its members.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 20, 1882.

SIR JAMES PAGET'S BRADSHAW LECTURE.

IF one result achieved by the delivery of the lecture reported in full in another part of our present issue, should be to stimulate a spirit of philosophical inquiry at all allied to that in which its author has set about its preparation, then the intentions of its foundress will be fulfilled in a way to exceed the most liberal expectations that might have influenced her in the action she took to promote at once the scientific study of medicine and the perpetuation of her husband's name. Some there undoubtedly will be whose anticipations of a lecture on "Some New and Rare Diseases" will be unfulfilled on perusal of Sir James Paget's address. Such persons as had been led to expect a series of descriptive statements in regard to so-called "new" diseases mentioned in recent contributions to medical literature cannot fail to feel disappointed with the actual material of the lecture; but even these will readily yield admiration of the eloquence and earnestness of Sir James Paget's exposition; while, at the same time, it will awaken in them, possibly with surprise, an entirely original appreciation of methods of investigation which had hitherto never presented themselves to their imaginations.

It is with the utmost gratitude that we welcome the utterances of so prominent and universally-recognised an authority as Sir James Paget in behalf of purely philosophical research in connection with disease. Through the influence his championship will exert in all places where pathology holds its rightful position among the sciences, these places will henceforth become the

centres of purer, more elevated, and less expedient-serving investigations; the sneers of observers of circumscribed vision, as to the importance of what may for the moment be termed speculative studies, will cease to paralyse the efforts of those who aim at discovering the "causes of things;" and we may justly prognosticate that what have been reviled in the past as purposeless researches will henceforth receive a rightful recognition as possible and proper aids in the search after truth.

Fortunately for us all, the time has now gone by when whoever would uphold the applicability of the doctrine of evolution to the solution of any problem had to voluntarily subject himself thereby to the contumelious criticism of his contemporaries. Equally fortunate, also, is it that the most brilliant of all present-day teachers have not only grasped the all-embracing significance of the terms "adaptation," "modification," and "environment," but are foremost as well to demonstrate the vast resources of explanation such knowledge opens up to the honest-souled inquirer. With rare enthusiasm, with a precision and a power that few can aspire to or attain, the Bradshaw lecturer on Wednesday last displayed to his hearers the illimitable fields before their exploring minds. For him—and, we trust now, for them as well—the "evolution" of disease possesses a meaning as comprehensive, as complete, and as instructive as the "evolution of species" possesses for the naturalist; and particularly is it true that "comparison" is as much the watchword of progress in the one case as in the other.

By dwelling on principles, in preference to crowding his address with illustrative descriptions of examples, we believe Sir James Paget to have acted with a discretion the more commendable because it must have required unusual determination to elect to follow this course. We could wish to express unqualified agreement with every utterance that fell from his lips, so greatly do we reverence the spirit which animated him; but we must at the same time so far dissent from his conclusion respecting the appearance of a "new" disease as to suggest that the premises on which it is founded may be fallacious. The examples quoted are, however, of a nature that renders it extremely difficult to combat even dogmatic assertions respecting them; and from every suspicion of dogmatism Sir James Paget is at all times free. But the frequency with which, since greater attention has been given to Charcot's joint disease, instances of its occurrence have been recorded, might be assumed to lend weight to the suggestion that even so unusual a complication had been overlooked. To the mind of a conscientious student, it is a difficult matter to understand how changes of such importance and magnitude can have been introduced, under the most favourable circumstances for their development even, in a period of time measurable by the experience of an individual. With a knowledge of the vast æons necessary to bring about the development of differences structurally comparable to those changes in animal forms submitted only to the action of natural forces, the attempt to conceive what amounts to instantaneous alterations is a supremely difficult one. But the very effort involved in making it is a

most salutary exercise, and will tend to correct the mental extravagance that hastens to apply a common "standard" to incompatible subjects; for we may be now, in endeavouring to associate our factors of explanation, on the brink of discoveries that will hasten intelligent understanding in respect to pathological details. The insufficiency of our present knowledge for enabling us to harmonise pathological with natural processes will by-and-by lead to the discovery of one of two things—viz., either that we are blindly ignoring a connection that exists as yet unobserved, or that we are neglecting conditions of absolute importance in the production of modifications in the body when it ceases to be governed by those laws merely of which we have cognisance.

Sir James Paget has expressly authorised the study of disease in the light of the laws of evolution. The fruitfulness of such study cannot be estimated yet; we are but on the threshold of illimitable discoveries; and of their effect on the future of mankind who can judge?

NIGHT LECTURES AND SHAM EDUCATION IN DUBLIN.

Not only the profession in Dublin, but the daily papers of that city, especially the *Freeman's Journal*, have been, within the past fortnight, somewhat excited by the determination of the Irish College of Surgeons to discountenance the delivery of evening lectures even to the extent of refusing the certificates of any school which continued the practice. The Council of the College on Thursday week adopted a resolution to the following effect:—

"That the Inspection Committee be instructed not to receive certificates from any School in which evening Lectures are delivered."

"That a copy of the foregoing resolution be communicated in writing to the Registrars of the Schools in Ireland, recognised by the College, and they be requested to furnish the Inspection Committee with a written guarantee to the effect indicated therein."

To English readers and those who are uninitiated in the mysteries of medical teaching in Dublin it becomes necessary to explain the reasons for this resolution, which, in the absence of a knowledge of the facts, might appear somewhat arbitrary exercise of collegiate authority. When we have laid bare the circumstances upon which the College has acted we anticipate that the general sentiment will be one of astonishment that this step or some other more stringent was not taken long ago to put down the disreputable traffic of which night-lecturing is one of the phases.

To readers of the *Medical Press* it is no news that in Dublin, for very many years past, the issue of certificates of "diligent" attendance on lectures, was, in many instances, an audacious fraud upon the public, the licensing bodies and the General Medical Council. In some schools, and with some teachers of course, these certificates were honest and trustworthy evidences that the student did avail himself of the teaching which the certificate represented, but it was notorious that in other schools these testimonials of diligence were simply sold by the dozen for so much hard cash to persons who almost never

entered the school, and who possibly, never were seen by the lecturer who testified to their diligence. Many teachers, indeed, made a sort of show of calling an occasional roll of the class, but the complete absence of the student's name from that list did not in the least prevent them from certifying his "diligent" attendance, whenever the fee for such certificate was forthcoming. Other teachers did not even make a pretence of inquiring whether the student was present at their lectures; they gladly welcomed students coming with the money in their hands for the purchase of any number of these documents, and some of them went so far as to sell them to persons whose appearance or name they never knew, and who came to buy certificates dated for lectures delivered years before. The culmination of this disgraceful system of false testification was, naturally, that numerous persons engaged in employments which engrossed every moment of their time from 9.30 a.m. to 6 p.m. every day in the week, officials in banks, public officers, &c., were induced to enter the medical profession as participators in the fraud. They remained in harness until within a few months of their examination, resigned their offices, purchased up a sheaf of these sham certificates, got themselves "ground" and crammed, and, after one or two futile shots at the examination, usually got through and went out in the world as surgeons and physicians almost without having ever seen a sick patient or taken a knife and forceps in their hand.

When the Irish College of Surgeons began the reform of its examinations the effect of the practicalisation of the test began to tell on this class of student. The grinders found that their pupils were rejected time after time, and that there was no longer any hope of passing men who had no effective knowledge of their business, and it became necessary to make provision for something in the way of continuous lecture and hospital work; but, as this class of students would, by no means, patronise a school or hospital which required them to resign office and devote themselves to medical study, the institutions which catered for them were obliged to utilise the evenings of week-days and the mornings of Sundays. Accordingly, they advertised night lectures, and one or more hospitals, without venturing to issue public notification, made it understood amongst the students that they would be glad to take the money of clerks, shop assistants, *et hoc genus omne*, and do all possible for them on Sundays without asking them to enter the hospital on week days. Moreover, by degrees the night lectures degenerated into evening "grinds," it being found possible to cram a greater number of "tips" into the average studential brain by the latter than the former method, but notwithstanding the change of form of the nocturnal instruction, the certificates of "diligent" attendance were issued to all who were willing to pay as if the instruction was in the orthodox form of lectures.

It is, we presume, hardly necessary for us to give reasons for condemning this system. It is hardly even essential that we should argue against the possibility of a shop or office assistant who has slaved at totting figures or selling tapes from 9.30 a.m. to 6 p.m. studying efficiently anatomy, physiology, or surgery from 7 to 10 at night, nor can it be necessary for us to point out that a young man squeezed

through an examination by such means may quite probably be guilty of manslaughter some time or other after he enters practice, when he finds himself for the first time face to face with disease and responsibility.

We do not doubt that a very few specially brilliant and industrious men, having got the needful smattering of their profession by such means, have, by dint of hard work and careful observation, learned after their entry into the profession to be good surgeons and physicians, nor do we for a moment wish to speak harshly of the hard working hopeful young men who, finding a corrupt system ready to their hands and persuasive grinders ready for their money, have made use of the tempting means to obtain a dishonest entry to the profession. The students are, of all parties to the transaction, the least to be blamed, and it is upon the teachers who have prostituted their office and upon the Colleges and the General Medical Council who have connived at the wholesale creation of sham practitioners by means of sham certificates and worthless cramming that our censure must fall.

It was in the winter of 1879 that two schools of medicine in Dublin, emboldened by toleration or coerced by competition, publicly announced that they were engaged in the night-lecture trade, and, as this was the first occasion that the Irish College of Surgeons had tangible evidence of the procedure, the Council of the College immediately manifested their stern disapproval of such an evasion of their regulations. Notwithstanding the vigorous opposition of the representative of one of these schools, the Council adopted a resolution declaring their entire disapproval of night-lecturing. At once the Directors of one of the schools in question—the Carmichael College—ceased the objectionable practice, explained that they had been induced to adopt it, though disapproving of the principle, by the competition of the other school, and by the apparent toleration of the system by the College. It is due to the Carmichael School to say that, before purity of teaching was the fashion, it distinguished itself amongst Irish teaching bodies by a strictness of educational integrity which was difficult to maintain, but for which the school is rewarded by the possession of a high repute. The second of the two schools—the Ledwich School—gave a formal assurance of a desire to conform to the wishes of the College of Surgeons; and the Council, therefore, considering the School pledged to abandon the system, rested without further action. Three years have elapsed since then, during which period the Council of the College has given daily proofs of its determination that old abuses shall cease absolutely, and new and less discreditable methods be enforced, and with this view, has bound itself to a new code of regulations to compel *bona-fide* study and honest practical work in hospital and dissecting-room. Everything possible to do to warn teachers of the firm determination of the College to tolerate no longer the night-lecture, Sunday-hospital system was done, yet no sooner is the present session opened than it is found that the Ledwich School which had been understood as pledged to the College is secretly hard at work at the old system. It is not necessary for us now to confine ourselves to speculation as to what may be taking place when we see it asserted in the daily papers that the lecture (or grind) room is crowded each night with young men who

have come there to submit their over-wrought brains and exhausted bodies to the pretence of a study of anatomy, and who are to receive, in respect of a couple of hours of night lecture, and the same period of Sunday hospital walking, a full tale of testimony that they have “diligently” studied medicine and surgery.

It was not to be expected that the Royal College of Surgeons in Ireland would submit to have its intentions frustrated and its reputation treated with contempt by any school over which it has control. The proceedings of the Council for the last two years in regard to educational and examinational reform have given full proof that a determination exists to purify the license in surgery granted by the College, and, if possible, the surgical profession in Ireland, from the stigma of past abuses. Whether or not lectures or certificates are deserving of being maintained does not enter into the argument. It is enough for the College that they are, for the present, considered necessary; and the Council is not disposed to lend itself to an evasion of that necessity, or to follow the example of the General Medical Council in tolerating a palpable and audacious setting at naught of the Collegiate regulations. It is well that each Dublin medical school should feel that the day of sham certificates, credit fees, and lucrative educational abuses is passed as far as the Irish College of Surgeons is concerned, and that, if that system is essential to the existence of any institution it must seek toleration for its proceedings in Scotland or other congenial centres of diploma-vending. We are confident that the Council of the Royal College of Surgeons in Ireland, having taken this step forward into professional confidence and public approval will not recede.

PERSISTENT VOMITING OF PREGNANCY.—II.

IN our last we concluded our analysis of Class II.

Class III. includes all those cases in which no mention whatever is made of the position of the womb, and is the largest class of all, comprising fifteen cases. We have thus far then, fifteen cases in Classes I. and II., in which it has been ascertained that version or flexion of some kind was present, and fifteen cases in which we have no positive evidence for or against displacements. There is in many of the cases in Class III., however, indirect evidence that makes it *probable* that displacement of one kind or another was not absent from all of them. This class embraces Nos. 3, 4, 6, 10, 12, 16, 17, 18, 19, 20, 21, 22, 23, 24, and 31. Case 3 was observed at the seventh month of gestation, when it was found that the internal os uteri was completely obliterated. Incisions were performed, and the child was born alive. Case 4 was one in which the cervix uteri was so sensitive that the slightest touch produced vomiting. Postural treatment brought about a cure. No. 6 was a case of Dr. Tyler Smith's. Abortion occurred spontaneously at five months. The patient did well for three weeks, and then rapid phthisis set in.

Dr. Hewitt quotes Dr. Smith's opinion that the sickness is “probably caused (incorrectly ‘cured’) by the distension and evolution of the dense structure of the uterus after impregnation, or by the pelvic irritation caused by

the gravid uterus before it emerges from the brim or from both these causes." No. 10 was Dr. Copeman's celebrated *bahn-brechende* or pioneer case, in which the os uteri was digitally dilated preparatory to inducing premature labour, and in which on the following day to his surprise and delight he discovered that he had unwittingly cured his patient. No. 12 was a similar case cured by Copeman's method. It will perhaps be noticed that we are making use of the somewhat shady word *cure* with respect to many of these cases; but it seems impossible to withhold it in those instances in which relief effected by treatment was instantaneous and so complete. Case 16 was Copeman's; vomiting ceased after digital dilatation of os as far as os internum. No. 17 ceased after digital dilatation of os uteri. Case 18. A sponge tent introduced to allay vomiting. Result not given. Case 19. Remedies failing, "the os was dilated digitally the tissue being found very hard and cartilaginous. Vomiting was at once relieved, and soon ceased altogether." Case 20. Dilatation, relief of vomiting; went to full term. Twenty-one and 22 both cured by digital dilatation. In No. 23 "the cervix, and especially the posterior lip was hard and gristly. Neither finger nor tent could be introduced. A long and slightly anterior curved throat forceps were used, and gently, but with some force, dilated." The effect was immediate in removal of the vomiting. This case was recorded by Mr. J. S. Fry, of Swansea. No. 24. The finger was introduced into the softened cervix as far as the internal os; after a week the sickness ceased. Case 31, the last in this class, is from Prof. Tarnier, of Paris. The patient was three months pregnant, and the vomiting was incessant. This was allayed by plugging the vagina with wadding.

The fourth class which comprises but one case includes all those cases in which the position of the uterus was stated to be normal. This in one of Dr. Copeman's cases. The patient was six weeks pregnant and the sickness had been present for three weeks. Position of uterus thought to be normal; posterior less hard and unyielding; os gradually dilated, and, after two days rest, cure. This case completes the number reported. As we have already stated, we have a total of thirty-one cases. Of this number fifteen patients were found to be the subjects of some form of displacement of the uterus; one case, and one only was observed to have her uterus in a normal position. Bearing these facts in mind, that in all but one of the cases in which the position of the uterus in cases of persistent vomiting was carefully ascertained, more or less displacement of one form or another was found to be present, it is not wonderful that Dr. Hewitt should claim some of the remaining fifteen cases, in which the position of the uterus was not ascertained at all, as cases of uterine displacement. This is what he indeed does. Speaking of Dr. Copeman's first three cases he says, "I stated that they offered a strong confirmation of the truth of the doctrines I had previously expressed on the subject. The explanation of Dr. Copeman's success I held to be that in his cases the operation of dilating the os uteri was itself the means of righting the uterus, for the os must have been pulled forwards in order to dilate it, and this would have the effect of tilting the body of the

uterus upwards, and thus assuming that they were cases of anteversion the operation reduced the displacement." As the writer himself says, the objection might be made that such an explanation as the one just given would not be a sufficient one in those instances in which the vomiting has persisted to as late a date as the eighth month of pregnancy. To this he replies to the effect that most probably there will have been acute flexion in the early months of pregnancy, that the flexion will, as a rule, have become straightened out as the uterus rises out of the pelvis, but that *the tissues of the uterus at the seat of the flexion are sometimes left in a diseased state, being stiffened and unduly resistant, and thus the irritation is kept up.* Dr. Copeman's treatment would undoubtedly tend to remove this stiffening and constraint." If Dr. Hewitt's claim and explanation be allowed at all, they may be held to apply to a large proportion of the fifteen remaining cases. Case 4 was Clay's in which the finger was introduced for the purpose of inducing labour, but desisting he found within twenty-four hours that the patient was able to take food. Cases 10, 16, 17, 18, 19, 20, 21, 22, 23, and 24, were instances in which dilatation after Copeman's method had given relief, in most cases almost instantaneously, and in all within a short period. No 31, (Professor Tarnier's) was one in which the sickness was allayed by plugging the vagina. This procedure would have the effect of steadying the uterus, if not of redressing any displacement, although vaginal tampons are frequently recommended and frequently employed for the very purpose of treating displacements. Moreover, in a considerable number of these cases the uterus is distinctly spoken of as "hard," "gristly," "condensed," conditions so frequently associated with displacements that it is more than likely there is a causal relationship between them.

We have now completed in an imperfect manner our analysis of the cases quoted and reported by Dr. Hewitt; we have now to follow him in his general commentary upon them, and upon the theories of others. He allows due weight to Dr. Barnes's opinion that the vomiting is due "to tension or stretching of the uterine fibres;" "for it seems likely that irritation might be produced by an undue degree of such stretching." He, however, sees no reason to change his conviction that compression is the "particular and tangible" element. He then goes on to quote Dr. Aveling's remarks to the effect that sickness "has undoubted relations to posture," and Clay's that congestion or tenderness of the cervix uteri are the causes. As bearing on the question under discussion, he mentioned the but recent acquisition of knowledge on the part of insular practitioners as to the frequency of uterine displacements in general, and the further one of the absolute silence of obstetric writers in regard to the complication of pregnancy with anteversion of the uterus. In concluding this part of the subject we cannot do better than use our author's own words in the recapitulation of his arguments. "1. Many women have no sickness, therefore, it is not an essential part of pregnancy. 2. It is mostly limited to the first half of pregnancy, being, indeed, in many instances limited to the first two months. This is precisely the time during which the uterus is most liable to suffer from flexion, for when the uterus rises into the abdomen such flexion can hardly occur.

3. It is produced almost universally by the standing or sitting position, which postures would be likely to intensify or exaggerate temporarily an existing flexion. 4. It is suspended in all but the very severe cases, if the patient remains in bed for a day or two, during which time no such exaggeration of the flexion by standing occurs. 5. It occurs in a very marked degree in cases which are known to be the subject of flexion at the time the pregnancy occurs. 6. Severe sickness and a decided tendency to abortion are very frequently associated in the same case, from which it follows that it is not unlikely at all events that the same cause is operative in producing both effects. 7. That for the last ten years or rather more I have found the sickness always to subside, or to undergo an immediate and remarkable amelioration by so placing the patient, or by so arranging the position of the uterus as to favour the reduction of the existing flexion."

With regard to treatment very little need be said. We have already indicated the principle he follows, and it only remains for us to add that positional treatment he looks upon as the one thing indispensable, associated with manual or digital redression of the displaced organ, and the insertion of suitable uterine supports, when deemed advisable.

Notes on Current Topics.

A New Conjoint Scheme.

THE Royal College of Physicians of London was recently induced, on the motion of Dr. Acland, to consider the propriety and possibility of arranging with the English College of Surgeons to hold a combined examination by the two Colleges, for the purpose of granting a double qualification. The matter was, we believe, referred to a committee, which has promptly set about the work before it, by stimulating action on the part of the College of Surgeons. The Council of this latter body at its meeting on Thursday last, appointed seven delegates to confer with the College of Physicians sub-committee, on the subject of the conjoint medical and surgical examination; and we may anticipate that some practical suggestion will be the outcome of the deliberations. The members of the combined committees are as follows: For the College of Physicians—Sir William Jenner, Sir Risdon Bennett, Sir William Gull, Dr. Acland, Dr. Sieveking, Dr. Ord, and Dr. Pitman; for the Royal College of Surgeons—Mr. Spencer Wells, Sir Jas. Paget, Mr. John Marshall, Mr. Cooper Forster, Mr. Erichsen, Mr. Savory, and Mr. Holmes.

A New Saccharine.

DR. CONSTANTINE FALBERG has discovered an "hydro-sulphamin-benzoic acid," which he describes as a white crystalline substance, very soluble in alcohol, but sparingly soluble in water, and characterised by a sweetness so great that the merest trace of the alcoholic solution in water gives it a distinctly sweet taste. Dr. Falberg estimates that it possesses more than twenty times the sweetness of cane sugar.

Another Prescribing Chemist.

ON Friday last, Dr. Danford Thomas, coroner for Central Middlesex, was engaged in holding an inquiry concerning the death of a woman who succumbed to the effects of a "sleeping draught" supplied by a chemist. The draught was supplied by a chemist's assistant named Armstrong, who said that on the preceding Monday evening he made up a sleeping draught containing six minims of laudanum and ten grains of *potassium*, and delivered it to a young man and woman who came for it for the deceased. He told them it was to be taken at once. Did not label the bottle, notwithstanding its poisonous contents, and volunteered the information that "it was a frequent thing to make up medicines for persons without having received a prescription." Dr. Thomas very justly characterised the conduct of the witness as most reprehensible and illegal, and ascribed the perpetration of many fatal errors to such loose and indefensible practices. The case was one on which even a coroner's jury was unable to agree without consideration; but the "intelligent twelve" were, as usual, given to condone the act of an assistant, and delivered their verdict as follows:—"That the deceased died from bronchitis, accelerated by a dose of opium prescribed by William Armstrong, assistant to Mr. Wooton; and they are of opinion that the said William Armstrong was guilty of great illegality in prescribing medicines, more especially for those he had never seen, and neglect in not labelling the bottle; and they further desire to add that the deceased's husband should have sought qualified medical advice when he saw his wife was in the condition she had proved to be." The coroner, in censuring Mr. Armstrong, observed that all he had to say was that the jury had taken a very merciful view of the case in returning the verdict they had, and in not returning a verdict of manslaughter against him. He (the coroner) trusted it would operate as a warning not only to him, but to chemists generally.

Prehistoric Diseases.

At a recent meeting of the West Kent Medico-Chirurgical Society a paper was read by Mr. H. W. Jackson, F.G.S., "On some Diseases and Injuries of Prehistoric Man," the contents of which are entitled to special consideration in their connection with Sir James Paget's address. The *Athenaeum*, in noting the paper, remarks:

"We are not aware that the subject has elsewhere been treated, except in a *thèse inaugurale* by M. le Baron, of which an abstract was laid before the Society of Anthropology of Paris last year. Mr. Jackson cited a case of exostosis in a femur found at Lozère; evidence of tooth-ache and of abscesses in the jaw found there and in the Belgian bone caves; of rheumatic ulceration of the joint in a jawbone and an astragalus from Furfooz, Belgium, and in other instances; a case of very extensive inflammation from the Caverne de l'Homme Mort, Lozère; a case of hydrocephaly from the Trou Rosette, Belgium, and one from the Canary Isles, observed by M. Verneau; hemiplegia in the skeleton found at Clisbury, Sussex; hip-joint disease in four cases recorded by M. le Baron; synostosis of the sutures in the Neanderthal skull; and numerous cases of surgical and posthumous trepanation. He also expressed the opinion that syphilis is a prehistoric disease, citing examples of it from Bray-sur-Seine,

in France, from Patagonia, and from Peru, and hazarded the suggestion that circumcision, which prevails in every division of the globe, and is almost universally performed with a stone implement, is a practice which has descended from prehistoric times. Flattening of the skull is known to have been practised, and fractures of bones and wounds of the skull are, of course, very frequent. Upon the whole, it may be concluded that the diseases of neolithic prehistoric man did not differ much from those of the present day."

As we have elsewhere suggested, we may fairly anticipate that the whole subject covered by these interesting speculations and discoveries will now become a matter for earnest and sustained inquiry.

Poor-law Medical Elections in Ireland.

Two elections were made last week which fittingly illustrate the very objectionable system at present in force in Irish dispensary and workhouse elections. On December 1st, Dr. Lydon was appointed medical officer of Arran Island, in room of Dr. Bodkin, resigned. The meeting had to be adjourned, owing, it was alleged, to undue influence being brought to bear on some of the members of the committee by the parish priest of the island on behalf of a candidate who refused to produce diplomas. The committee now left the matter in the hands of the guardians, as they believed there could not be a meeting of their body called with safety in Arran, as the police could testify.

A meeting of the Carlingford Dispensary Committee was also held for the purpose of electing a medical officer for the district. A great deal of interest was manifested in the proceedings, as on two occasions since the position became vacant attempts were made to elect an officer, but on both occasions the voting was equal, and the election abortive. Every available vote was obtained, one gentleman having been taken from the opposite end of the county, and another from Dublin. On this occasion the voting was—For Dr. Lennon, 7; for Dr. Davis, 5.

Unqualified Ship Surgeons.

At the last meeting of the Manchester Medico-Ethical Association, held on the 8th inst., Dr. Irwin introduced for discussion "The Position of Ship Surgeons," and the following resolution was unanimously adopted:—"That this Association is convinced that the medical and sanitary departments of our Mercantile Marine are in a highly unsatisfactory condition, and that the lives of passengers are frequently endangered thereby. That this Association desires to press upon the Government the necessity of an immediate inquiry into the position, status, and efficiency of surgeons upon passenger ships."

THE Council of the Clinical Society of London have nominated Dr. Andrew Clark as the President of the Society for the next year; and the Council of the Harveian Society have nominated Dr. Symes Thompson as the President of that Society. Dr. Gervis will be the new President of the Obstetrical Society of London.

King and Queen's College of Physicians in Ireland.

THE following Fellows of the College have been appointed Examiners for Membership for the year 1883:—1. In Principles of Medicine, including Medical Anatomy and Medical Chemistry—J. Mallet Purser, M.D., and J. Magee Finny, M.D.; 2. In Practice of Medicine, including Principles of Public Health—Francis R. Cruise, M.D., Vice-President, and George F. Duffey, M.D.; 3. In Clinical Medicine—Arthur Wyane Foot, M.D., and Christopher J. Nixon, M.B. The Court of Examiners for the certificate in Sanitary Science during 1883 will be constituted as follows:—1. Engineering—Mervyn J. B. Pratt, C.E., M.A., M.E. Univ. Dub.; 2. Law—George Roberts Price, B.A. Univ. Dub., Barrister-at-Law; 3. Etiology and Prevention of Disease—Francis R. Cruise, M.D., Vice-President of the College; 4. Chemistry, Air, Water, Food—Walter George Smith, M.D.; 5. Meteorology, Climatology, and Vital Statistics—Francis J. B. Quinlan, M.D.

Chest Development by Exercise.

DR. CATHCART, Lecturer on Anatomy in the Edinburgh School of Medicine, in a lecture delivered at the Edinburgh Health Society a few days ago, gave, as to the effects of exercise in expanding the chest, some striking facts which related to a school where physical exercises had been systematically carried out. The effect of regular exercise was shown as follows:—New boys, aged fourteen, average chest measurement, 29.3; at fifteen, 30.16; at sixteen, 32.0; at seventeen, 32.6; and at eighteen, 32.5; while former boys measured respectively 30.6, 32.1, 34.2, 35.8, and 36.8.

The Supply of Subjects in America.

A BAND of resurrectionists has been captured with six bodies, intended for the Philadelphia Medical College, in their possession. The recovered corpses have been identified. The capture was planned by some reporters attached to the Philadelphia press, who carried it out successfully as amateur detectives. The captured men are now in gaol awaiting their trial.

Baths and Wash-houses for Dublin.

AMONGST other matters recently discussed in the Dublin Corporation was the long-talked one of the provision of public baths and wash-houses. The Public Health Committee reported that a portion of the property they would be obliged to acquire for the new Street Improvement scheme in connection with the new Swing Bridge would be available as a site, and the locality, it is said, is much more favourably circumstanced for such a project. The Committee has now obtained possession of ground in Shoe Lane, which is considered will be sufficient for the purpose, and the estimated cost of the buildings is £5,000, and the machinery about £1,200.

ONE hundred and ninety-six bodies have been cremated in Milan in the last five years.

Operations on the Eye in the United States.

THE *Phil. Med. Reporter* gives the following interesting statistics by Dr. Little:—Of 107,383 eye cases in the ophthalmic and general hospitals in the leading cities, 19,037 required surgical procedures, of which 862 were enucleations for some of the many forms of objective traumatism, principally on account of the dread of a presence of sympathetic irritation or ophthalmia of the other eye. Some were for intra-ocular conditions, and a few for cosmetic purposes. Thus 17·7 per cent. of ophthalmic work is operative, and 4·5 per cent. is enucleative. This percentage of the removal of the eyeball should be higher than the statistics derived from the public clinics show, as this class of cases is more apt to seek private advice. The importation of artificial eyes is about 10,000 annually, and recently the manufacturing of them has become a home industry.

Substitute for the Sand-bath.

FROM time immemorial chemists have used a sand-bath where a temperature is to be obtained higher than that of the boiling of water or of oil. The method is not wholly rational, however, sand being a very bad conductor of heat. Herr Kristalba has lately recommended the substitution of pounded fragments of graphite; they let the heat pass much better, do not oxidise, and do not soil the enclosing vessel. *L'Electricité* commends the method to electricians who have to make researches in thermoelectricity, adding that small shot of iron would serve nearly the same purpose. For more intense heats, it is known, melted lead can be used.

Compulsory Notification.

MR. MARTINEAU, a member of the Birmingham Town Council, addresses a letter to the last issue of the *British Medical Journal*, in which he states that by a majority of twenty-seven to twenty a number of compulsory notification clauses, which had more *solitu* been smuggled into a local Bill, were excised. Mr. Martineau makes the following sensible observations on the subject: "If we could have taught the people the means of isolation, and its need, such Acts as Hastings's would never have been mooted; and, if they are passed, no amount of fines and penalties can make them effective. People (neither patients nor doctors) happily, I think, cannot be dragooned into sanitation. Your fines, as the evidence taken before the Liverpool deputation amply shows, lead merely to concealment. Concealment leads to a high death-rate, as in Bolton and Blackburn, where the deaths from typhoid fever averaged 1 death to 4·4 and 4·2 cases respectively, the general English average being 1 in 6·8. Thus the doctors are prevented from bestowing that curative blessing on the community which is their function. They are not called in, and the very regulation meant to eradicate disease tends to aggravate it, by closing its legitimate source of cure. I think there is all the difference between compulsion and a direct appeal to the public spirit of an enlightened fraternity. I, for one, am content to appeal to the spirit of self-sacrifice for the common good manifested by the medical profession, and to rely on the invaluable help which they, in their daily mission of

beneficence, can render us, by information either as to the prevalence of infectious sickness or (still better) as to the existence of conditions likely to induce disease. I am glad that the Council has said in effect, by its resolution on Tuesday, that it will not subject them to the indignity of incurring the penalty of '40s. and costs,' or £5 in case of a second omission to notify. We do better; we appeal to their public spirit as citizens, to their philanthropy as men, that they will help us in the work of raising our fellow-men to that higher power of life which is only possible to the '*mens sana in corpore sano*.'" We can assure Mr. Martineau that his confidence in the profession is not misplaced. There are many practitioners who will refrain from notification, in spite of any law which may be enacted, but we do not believe that there is one base enough to conceal disease or spare any effort to crush it out, in order that he may benefit by its dissemination.

The Medical Reform Bill.

THE *British Medical Journal* announces in large type, and apparently with authority, that it has "good reason to believe that the desired result has been attained, in so far that the Government are now resolved to prepare such a measure on the basis authoritatively laid down by the Commission; and that the Bill will be drafted and introduced by the Government having this object, and drawn upon these lines. The announcement which we are thus able to make will be received with great satisfaction by the immense majority of the profession—so overwhelming a majority, that we feel justified in saying that the Government will, in this matter, receive the active support of the profession at large."

The Metropolitan Hospital Sunday Fund.

THE annual meeting of the constituents of the Hospital Sunday Fund was held in the Egyptian Hall of the Mansion House on Wednesday last, under the presidency of the Lord Mayor. From the annual report presented we gather that during the past year there had been an increase in the number of contributing congregations, and a consequent increase in the sum collected. In 1873 the amount collected was £27,700, whereas this year it was £34,146. The working expenses amounted to £1,132—a somewhat large sum considering that the office of the executive is no burthen to the fund. We fail to understand why the Council should expend money for printing statistical tables of the hospitals, giving the cost of patients and management, simply "for the special use of the members of Council." Why are not these tables made available for every one interested in the fund, and in the good management of hospitals in general? There is one other point about which we should like to have information. At a former meeting of the constituents of the fund a scheme was proposed for the retirement, year by year, of a certain number of members of Council. Why is this to be shelved? And why is it deemed expedient to give so useful a proposal the go-by? We have it on good authority that there are a large number of members of Council who are never present at any of its meetings. Under any circumstances, it would certainly be useful to infuse new blood both into the Council and work of Hospital Sunday.

The 10th of June is the day fixed upon for Hospital Sunday of next year (1883).

The Cause of Goitre.

J. CARRET has given in the *Mon. de la Policlinique* some results of his inquiries into the above subject. The disease is produced, if his conclusions are found correct, by a micro-organism that lives in the soil, and at certain seasons of the year is met with in the water. Boiling the water is a prophylactic. M. Decés remembers that at one time the only drinking water in Rheims was obtained from wells dug in the chalk. From the year 1846 water from the river has been carried into the town, a change of supply that resulted in a rapid diminution in the number of cases of goitre, and in a short time a complete disappearance of the affection. M. Carret has determined a maximum zone, viz.—from a height of 1,000 to 1,100 metres in the southern declivities of Savoy, and from 400 to 500 in the northern slopes, the one being an isotherm of the other.

The Medical Department and the Decease of Regimentalism.

MR. CHILDERS having so recently, in reply to a Parliamentary question, quoted the assertion of Lord Cranbrook that the "regimental system was dead, and could not be revived," and having endorsed this opinion in the fullest and most uncompromising manner, would it not be for the benefit of both the army and the profession that the committee now sitting, and in whose impartiality the public and the Medical Department have alike perfect confidence, should, by the suggestion of a name which would embrace both the medical officers and their hospital subordinates, set the seal of an official epitaph to the departed regimental system, and thus cause all serving under the new organisation to direct their efforts to perfect that principle of administration to which both Conservative and Liberal Secretaries of State for War have asserted that the medical service, however altered in detail, must, in the main, be adapted? We would therefore appeal most earnestly to medical officers, be they few or many, who regret the decease of regimentalism, to accept the event as inevitable, and in this most serious crisis in the career of their department to bear in mind the simple adage that "union is strength," remembering that, however apparently flattering may be the efforts of regimental colonels to regain "their own doctors," it would be contrary to human nature to suppose that their chief aim is the advancement and advantage of the Medical Department as a whole. It was not by the false elevation of parasitic existence that the Royal Engineers and Royal Artillery have become the distinguished corps they now are, but by forcing upon the conviction of the State the value of the services which they could render when they combined, one and all, to attain the object for which they had been called into existence. The duel between forts and ships, between guns and armour-plates, between shelter-trenches and projectiles may be brought to the highest point of scientific perfection, but there still remains the fact that, up to the present, for every one man killed by all these expensive machines, at least five have been lost to the State by preventible disease. In this fact lies the future of the Medical Department, and in proportion

as the nation becomes more and more educated to its perception it will the more strenuously insist on the corps in whose hands the prevention lies being given its proper position and being freed from the trammels of such non-professional interference as is still forced upon it for the purpose of upholding the jealous monopoly of military command.

Fraudulent Glycerine.

DR. GEISLER reports in the *Pharm. Centralhalle* an investigation of a sample of glycerine which a Dresden house had sent him, and which had been bought on the Prague market. Outside the package it was marked "Not adapted for internal use." It was of a yellowish tinge, and almost clear; rubbing on the hand it had an oily feel, and left behind a peculiar dryness; the taste was bitter and disagreeable; the sp. gr. 1.269. The bottle was labelled "Chem. Glycerin., white, 30°." It contained no trace of glycerine, but was a mixture of magnesium chloride (11.87 per cent.), starch, sugar, and dextrine with water.

The Royal Medical Benevolent College.

IN consequence of some unfortunate manifestations of insubordination, the Council of the Royal Medical Benevolent College at Epsom have thought it advisable to propose certain amendments in the Bye-laws which shall enable them and the head-master to meet with promptitude future breaches of discipline. For this purpose the Council have called a general special meeting of the governors and subscribers for Wednesday (this day), at 3 p.m., to consider and ratify the necessary alterations in the Bye-laws, to which there certainly ought to be no objection.

President Garfield's Medical Attendants.

THE discharge of the bill for attendance on the late President is, according to the *New York Med. Record*, still further complicated by a claim of Mrs. Elson against his estate of 10,000 dols. for "skilful attendance in her professional capacity as a physician." It will therefore have to be considered as coming within the limit of 35,000 dols. allowed to the physicians under Act of Congress.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 34; Bombay 25, Madras 33; Paris 26; Geneva 18; Brussels 23; Amsterdam 26; Rotterdam 29; The Hague 26; Copenhagen 21; Stockholm 22; Christiania 21; St. Petersburg 45; Berlin 22; Hamburg 23; Dresden 23, Breslau 26, Munich 28, Vienna 24, Prague 25, Buda-Pesth 26, Trieste 31; Rome 23; Turin 20, Venice 26; New York 21, Brooklyn 21, Philadelphia 19, and Baltimore 27.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Derby, Leicester 16; Plymouth, Brighton, Bolton 17; Cardiff, Bristol 19; Bradford, Halifax 20; Oldham, Portsmouth, Birmingham, Nottingham, Huddersfield 21; Norwich, Birkenhead, London 22; Manchester 23; Edinburgh, Dublin, Sheffield 24;

Newcastle-on-Tyne, Wolverhampton 25; Preston, Salford 26; Liverpool, Blackburn 29; Glasgow 30; Leeds, Hull 31; Sunderland 35.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

EDINBURGH UNIVERSITY.—NEW REGULATIONS AS TO EXAMINATIONS.—Students will hear with pleasure that the question of altering the date of the first professional examination is now engaging the attention of the Senate, and that the consent of her Majesty's Privy Council will be asked early next year. Hitherto, students could not enter for their first examination in botany, natural history, and chemistry for eighteen months after commencing their studies. And as the regulations were so cleverly arranged as to the number of classes required, students were compelled to take out two courses of botany or natural history. This, though convenient for the respective professors, was a great scandal, and to which we have repeatedly drawn attention. This, we are glad to say, is on the eve of removal, and students will in future be able to present themselves for examination after a winter and summer session of study. We hope also that the dates of the first and second examinations will be approximated; as they now stand, three courses of anatomy have to be taken out. The regulations of the University only require one course, but the arrangements of the examinations have been so devised as to compel three courses. At present, only one year of practical study is allowed, by driving over the examinations in anatomy and physiology to the end of the third winter. The existence of a Royal Commission and a slowly awakening public have to be thanked for these small mercies.

PROPOSED ADDITIONAL MEDICAL CLASSES IN THE UNIVERSITY OF ABERDEEN.—The Medical Faculty of the University have agreed to the following motion, submitted by Professor Struthers, for the purpose of encouraging the opening of special classes in certain subjects in the medical school:—"That the Faculty—regarding with satisfaction the provision already made for special instruction in diseases of the eye, and in diseases of the teeth—record its willingness to consider favourably, and to recommend to the Senate for recognition, applications from members of the profession who may desire to give special instruction in diseases of the ear, diseases of the larynx, diseases of the skin, or in other subjects in which it is usual to give special instruction in schools of medicine; provided that the instruction proposed to be given is of a practical and useful character."

THE FEVER EPIDEMIC AT ABERDEEN.—The Managers of the Aberdeen Royal Infirmary, on the 11th inst., empowered a committee to improvise as a ward a large hall in the hospital used as a board meeting-room, in the event of the necessity arising from the fever epidemic prevailing in the city. Lord Provost Easlemont stated to the meeting that the number of patients in Aberdeen Infirmary was higher than it had been for nineteen years. He stated that the epidemic hospital in Aberdeen was available in the event of the spread of the fever, whither patients labouring under infectious diseases might be taken, and that in the event of the board meeting-room being brought into requisition, the Infirmary managers need not be afraid to turn up at the next meeting held in it, because good care would be

taken that cases of disease of a non-infectious character only would be treated there.

VITAL STATISTICS FOR NOVEMBER.—From the Registrar-General's monthly we learn that during the month of November there were registered in the eight principal towns of Scotland the births of 3,491 children, of whom 1,727 were males and 1,767 females. Of these, 3,180 were legitimate, and 314 illegitimate, being in the proportion of one illegitimate in every 11.1 births; or the illegitimate births constituted 8.9 per cent. of the whole. In Greenock, 4.4 per cent. of the births were illegitimate; in Leith, 5.6; in Paisley, 7.9; in Edinburgh, 8.5; in Glasgow, 9.3; in Perth, 9.4; in Dundee, 9.5; and in Aberdeen, 13.4 per cent. The deaths of 2,420 persons were registered during the month, of whom 1,173 were males, and 1,247 females. Allowing for increase of population, this number is 52 under the average for November during the last ten years. A comparison of the deaths registered in the eight principal towns shows that in November the mortality was at the annual rate of 20 deaths per 1,000 persons in Edinburgh, Aberdeen, and Greenock, 21 in Leith, 22 in Perth, 25 in Dundee, 26 in Paisley, and 27 in Glasgow. Of the 2,420 deaths, 1,000 or 41.3 per cent. were those of children under 5 years of age. In Perth, 31 per cent. of the persons that died were under 5 years of age; in Edinburgh, 32; in Aberdeen, 33; in Paisley, 38; in Leith, 39; in Greenock, 43; in Glasgow, 45; and in Dundee, 50 per cent. The miasmatic order of the zymotic (epidemic and contagious) class of diseases proved fatal to 381 persons, and constituted 15.9 per cent. of the whole mortality. This rate was exceeded in Glasgow, Dundee, and Perth. Whooping-cough was the most fatal epidemic, having caused 91 deaths, or 3.8 per cent. of the mortality. In Glasgow 5.2, and in Dundee 4.3 per cent. of the deaths were ascribed to whooping-cough. Fever caused 31 deaths; of these 9 were tabulated as typhus, 19 as enteric, and 3 as simple continued fever. 7.3 per cent. of the deaths in Perth resulted from fever. 57 deaths were caused by scarlatina, 45 by diphtheria, 45 by croup, 43 by diarrhoea, 27 by measles, 13 by metria, and 4 by dysentery. One death attributed to cholera was caused by choleraic diarrhoea. 61 deaths were ascribed to apoplexy, 58 to paralysis, 155 to diseases of the heart, 41 to hydrocephalus, and 67 to premature birth debility. The deaths from inflammatory affections of the respiratory organs (not including consumption, whooping-cough, or croup) amounted to 644, or 26.6 per cent. Those from consumption alone numbered 223, or 9.2 per cent. 95 deaths resulted from violent causes, of which 8 were suicidal. 8 deaths were attributed to the direct effects of intemperance. 5 males and 5 females were aged 90 years and upwards, the oldest of whom was a widow 97 years of age.

OUTBREAK OF TYPHUS FEVER IN EDINBURGH.—At a meeting of the Public Health Committee of the Town Council, on the 12th inst., it was stated that during the month 345 cases of infectious diseases were reported by medical men in terms of the compulsory notification clause of the local Act. In connection with the health of the city, the Medical Officer stated that an outbreak of typhus fever had occurred in a portion of Buchanan Street, Leith Walk, which is within the municipal boundary, 16 cases having been reported out of two tenements, 2 resulting fatally. The first case reported was believed to have caught the infection in Leith, and in consequence of what Dr. Littlejohn called the overcrowded and filthy condition of this comparatively new tenement, the disease has rapidly spread. Under the operation of the compulsory notification clause, notice was at once given to the au-

thorities, and each case as it arose promptly dealt with. In the case of one family, it was considered advisable to remove two of the members to a special ward in the Canongate Hospital, where they remained for one week in quarantine, the house and furniture being in the meantime specially cleansed. An examination of the drains was made by the Burgh Engineer, and a considerable leakage of water discovered, rendering some of the houses in the under flat very damp; but apart from this circumstance, the drains appeared to be in good order.

Literary Notes and Gossip.

WE learn that a Portuguese translation of the "Hand-book of Midwifery for Prussian Midwives" is about to be undertaken. The book, which was favourably reviewed in these columns some few months since, is to be translated from the English version of Dr. Burton, of Liverpool, published in 1880.

DR. FERRIER, F.R.S., is, we understand, preparing for the press a new and enlarged edition of his work on "The Functions of the Brain," which will embody many new observations and experiments by the author, as well as a critical examination of the various experimental and pathological investigations of recent years bearing on the question of the localisation of cerebral functions.

WE are asked to announce that the late Dr. Peacock, so long connected as physician and lecturer with St. Thomas's Hospital, has left a bequest sufficient to establish a Scholarship in the Medical School of the value of forty guineas. The Scholarship will be tenable for two years, on the same terms as those of the "Musgrove" Scholarship, founded by the late Sir John Musgrove, formerly president of the hospital, and will bear the title of "The Peacock Scholarship."

"AMBULANCE LECTURES," by Lionel A. Weatherly, M.D., has reached its fifteenth thousand, which shows that, as a text-book for the classes formed under the auspices of the Order of St. John of Jerusalem, it has achieved the aim of its author—viz., "that it might form a useful work for policemen, railway officials, and other men engaged in large works, as well as for the public at large." The present edition has a chapter added on nursing, poultices, blisters, fomentations, leeches, &c., of great practical utility.

PARTICULARS of the Warren Prize Essay have reached us from America, which is open to competition to the profession in all countries. The premium offered is of the value of four hundred dollars for the best dissertation, worthy of a prize, upon the following subject: "Chronic Bright's Disease (parenchymatous and interstitial nephritis). The Nature and Mutual Relations of the Derangements in the Circulatory and Secretory Organs." Essays must be forwarded to the Resident Physician, Massachusetts General Hospital, Boston, on or before February 1, 1883.

WE have pleasure in calling attention to a very interesting and useful monograph, entitled "Hospitals: their History, Construction, and Hygiene," by J. Francis Sutherland, M.D., Surgeon to H.M. Prison, Glasgow. (Edinburgh: E. and S. Livingstone.) It was Dr. Sutherland's thesis for the M.D. degree in the University of Edinburgh, for which a gold medal was awarded. The volume is profusely illustrated with drawings and plans of British, French, and American hospitals, a short but interesting account being given with each. The book is very readable, and contains matters of interest for the general as well as the professional reader.

THAT very valuable publication, *The American Journal of Obstetrics*, which is becoming almost as popular in this country as in the United States, is about to undergo another change. Formerly it was issued as a quarterly; last year a monthly supplement was added; we understand it is now the intention of the publishers to incorporate the two, and

to issue it from the new year as an enlarged monthly, the subscription price remaining as heretofore. We doubt not in this form it will become even more acceptable to that large class of obstetricians it so ably represents in all English-speaking countries.

THERE is but one journalistic change announced amongst the medical periodicals of the United Kingdom for the new year, and this relates to our very enterprising, and at times amusing, little contemporary, *The Students' Journal and Hospital Gazette*. Those of our readers who remember this publication in their student days as a fortnightly at fourpence will behold it henceforth as a weekly at a penny, carried on, we are informed, on the same lines as for many years past, in the interests and for the instruction of medical students and junior practitioners. It gives us, therefore, sincere pleasure to wish our little contemporary, which has done so much useful work in the past, "a prosperous new year."

SIMULTANEOUSLY with the publication of Dr. Cameron's essay on "Microbes" and Koch's "Bacillus" comes a new and enlarged edition of Drs. Loew and Bokorny's theory of "The Chemical Conditions of Life." Some of our readers may have read the former essay of the Munich authors, and will remember their contention to be that the force of life lies in the energy of the aldehyde group, and that simple alterations in the organic conditions of protoplasm are sufficient to explain what has been familiarly known as the *vis vitalis*. The tenability of such a solution is certainly open to very grave and tangible objections, but the way it is worked out is exceedingly ingenious.

DR. H. AUBREY HUSBAND has published, through Messrs. E. & S. Livingstone, of Edinburgh, "The Student's Pocket Prescriber," consisting of a collection of prescriptions issued in a handy form, suitable for the vest pocket. Such a work is likely to find considerable favour, not only among the young prescribers to whom it is especially addressed, but also with many of more advanced status, to whom the difficulty of deciding offhand on a suitable prescription in a given case is not altogether unknown. These formulae are classified on a therapeutical basis, and appear to have been carefully collected with a view to securing reliable and generally suitable associations of remedies. A few pages of introduction are prefixed to the body of the work, wherein the author offers some sensible and comprehensive suggestions on the art of prescribing. "The Pocket Prescriber" is an excellent little work, and is certain to become a great favourite.

A NEW candidate for favour among dermatologists has recently appeared in the shape of a "Journal of Cutaneous and Venereal Diseases," edited by Drs. Piffard and Morrow, both of New York. The journal will be published monthly by Wood & Co., of New York, and is valued at two and a-half dollars, or ten shillings per annum. No. 1. is enriched with a coloured illustration, and contains notes on the development of trichophytosis cruris, on psoriasis, on syphiloderma, and on acne, in addition to reviews and a selection of extracts somewhat less voluminous than is customary with American journals. No. 2 contains a brief account of a case of sclerema neonatorum, and an almost unique history of total sloughing of the penis due to a primary sore. The work is well printed on good paper, and ought to have little difficulty in making its way. We shall be glad to welcome its regular arrival in the future.

THE Clinical Society is to be congratulated on the encouraging way in which the importance of its successive volumes of "Transactions" is maintained. The fifteenth of these valuable additions to our literature has just been issued, and in no respect can it be said to be less worthy than its predecessors of the Society which fathers it. An especial feature of the work is the Report of the Committee on Excision of the Hip-Joint, which is likely to serve as the basis for future decision in a good many cases when the operation in question has to be considered. No less than forty-seven communications are included in the volume, which numbers over 320 pages, and contains eight plates, four being coloured, besides seven woodcuts. In the preface, the Council remark on the importance of discussions which took place

on the papers read. The absence of any notes to indicate the particulars of such importance might be worthy of consideration with a view to their addition in future volumes. Nothing, however, can detract from the high value of this series of "Transactions" as it stands.

WHILE deploring the fact that the law is powerless to stop the growing issue of, and the demand for, trashy literature for the young, it is gratifying to learn of the success attained by legitimate publications, which can honestly lay claim to the title of healthy and instructive food for the youth of both sexes. We refer to the volumes now before us, for the present year, of "The Boy's Own Paper" and "The Girl's Own Paper;" and to those of our readers who are in doubt what book to give as a Christmas or New Year's present to their juveniles, we cordially recommend these works. Each volume is handsomely got up, is full of instructive matter, sound moral tales, simple experiments, and games which were wont to amuse us in our boyhood, with the added novelties of modern ingenuity and invention. The name of Dr. McLeod as editor will be a sufficient guarantee of the literary fare thus provided, and its variety is ably seconded by the elegant and attractive forms in which the publishers have produced the two works.

By the death of Dr. Edwards Crisp, the profession has not only lost a sound physician, but one of her most accomplished *littérati*. His papers on Medicine, Surgery, Zoology, Physiology, and Pathology in the medical and zoological journals and in the Society's Transactions were alike distinguished by their originality and numbers. He obtained the Jacksonian Prize for his work on the "Structure and Diseases of the Large Vessels;" the Astley Cooper Prize for the essay "On the Structure and Use of the Thyroid Gland;" the Astley Cooper Prize, again, for his essay "On the Pancreas;" the Jacksonian Prize a second time for his treatise on "Intestinal Obstructions within the Abdomen;" the Fothergillian Prize for an essay on "Croup and Diphtheria." But Dr. Crisp's was a disposition which chafed severely under failure, and the withholding of the Carmichael Prize from any of the competitors, the year he sent in his essay, on account of "insufficient merit," was a severe blow to his sensitive nature, and he wrote but little afterwards.

BEST practitioners must be sometimes puzzled to select one particular variety of a "Visiting List" for their use from the many forms which present themselves. Admirable as most of these aids to performance are, it is a really difficult matter to award the palm to any one especially, and all the more so since each publisher seems to be alive to the necessity of making such constant additions and improvements to his publications as shall make them more and more indispensable to the profession. Among the works of this description issued in readiness for 1883, that of Messrs. John Smith and Co., of Long Acre, and entitled "The Physician's and Surgeon's Visiting List and Diary," is, however, entitled to be regarded with more than usual favour, because of the length of time during which this firm has published a similar companion—the present is the 37th annual issue—and also on account of the exceptionally useful nature of the contents of the book. As well as space for the entry of daily memoranda for the record of visits to 26 patients, and of obstetric and vaccination engagements, &c., &c., room is provided for the registration of addresses of patients, nurses, &c., and for other important details bearing on professional life. In addition to these diary arrangements, there is included a very considerable amount of valuable information of a kind that will be found eminently useful by practitioners of medicine at almost every turn. The "Table of Doses" introduced some years ago is now supplemented by a list of non-official and eclectic remedies, the incorporation of which cannot fail to enhance the usefulness of the work. It is indeed a most excellent pocket companion, and deserves all the success it has achieved.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, November 15th:—On the Relation of the Chest Movements to Prognosis in Lung Disease," by Arthur Ransome, M.D. Drink and Strong Drink, by B. W. Richardson, M.D., F.R.S. The Relative Mortality after Amputations

of Large and Small Hospitals, by Henry C. Burdett. Nerve Vibration and Excitation, by J. Mortimer Granville, M.D. Microbes in Fermentation, Putrefaction, and Disease, by Charles Cameron, M.D., LL.D., M.P. Injuries of the Spine and Spinal Cord, and Nervous Shock, by Herbert W. Page, M.A., M.C. Cantab. On Duty under a Tropical Sun, by Major Leigh Hunt and Alex. S. Kenny, M.R.C.S.

Literature.

THE SURGERY OF DEFORMITIES. (a)

THE production of a good and comprehensive handbook on orthopaedic surgery may justly be held to entitle its author to receive the congratulations of that increasing number of surgeons and students who feel the want of some such aid to the study and treatment of deformities. Mr. Noble Smith has satisfactorily achieved the task of writing a treatise possessing very considerable merits, and containing a trustworthy account of our present knowledge in this department of practice. In the opening chapter of his work he discusses "the nature of deformities" in a careful and instructive fashion, especial attention being given to several subjects in this connection, all of which have the deepest interest for the inquirer. Excess or arrest of development; the influence of mechanical injuries; the influence of faults in the ovum, and of heredity; the nature of acquired deformities, and the history attaching to them—all these subjects are duly entered on and followed out with so much clearness of description that the chapter is a valuable contribution to our literature in itself. "Club-foot: its Varieties and Treatment," forms the subject of the second chapter, which is well illustrated with pictures of varieties of the deformity, and with representations of the instruments and appliances to be employed in remedying it. We cannot help suggesting that it might have been possible to obtain some figures of somewhat later date than those quoted from Mr. Lonsdale in reference to the frequency of the different kinds of talipes; for although the inferences deduced therefrom would be unaltered by a study of further analyses, yet the records of hospitals for recent years are sufficiently accessible to permit returns from them to be quoted. In a second edition of his book Mr. Noble Smith might think it worth while to make this improvement. The chapter on "Deformities of the Digits" is a most excellent *résumé* of the subject, and includes a description of all the approved operations, and those as well of most recent introduction. Morbus coxae naturally receives a considerable share of attention, our author agreeing with Billroth's opinion as to its etiology, which rejects the theory that the disease is commonly a serofulous affection. Excision is advised as a last resource only, and only after thorough rest of the joint has failed to control the disease. Mr. Smith's experience induces him to assert that if this mode of treatment is carried out early in the progress of these cases, excision would be very rarely called for. The advice given in respect to ankylosis and old unreduced dislocations is deserving of careful study, and confirms the opinion of those who hold that much benefit may be done in them by the adoption of gentle means of treatment. Deformities of the spine, and caries of the spine, occupy, of course, a considerable space in this work. Writing on lateral curvature, our author condemns the employment of many forms of support in use, approving only of those invented by Mr. E. J. Chance, consisting of a belt and upright rod, with adjustable pads for regulating pressure where required. He observes that, "if a case is treated in the earlier stage the support may and should be dispensed with; but the objections which have been more or less justly raised against those apparatuses which interfere with all muscular action do not apply to the support here recommended."

Dr. Morton's treatment of spina bifida by injection of the iodo-glycerine solution is advised, on Dr. Morton's own authority, in those cases where tapping is of no avail, Mr. Smith agreeing as to the value of the results obtained by this method, but at the same time urging the dangerous risk attending all operations on such tumours.

(a) "The Surgery of Deformities: a Manual for Students and Practitioners." By E. Noble Smith, F.R.C.S. Ed., L.R.C.P. Lond., &c. Illustrated. London: Smith, Elder & Co.

The last chapter of the book is mainly devoted to a consideration of "Rickets, including Genu Valgum." To it, however, two short sections on osteomalacia and osteomata respectively are appended.

We have not attempted to do more in this notice than convey a general idea of the scope and character of Mr. Smith's work. Enough, however, has been said to indicate the valuable features it presents. A manual of this kind has long been a *desideratum*, and while conveying to its author an expression of the satisfaction derived from perusal of its contents, we can safely commend it to those who seek to obtain a trustworthy guide to the main facts connected with the nature and treatment of deformities of the human body.

Obituary.

SIR THOMAS WATSON, BART.

To but few is it given to reach the venerable age of him who has recently gone from amongst us full of years and in honours richer than any of his peers. Long, however, though his life undoubtedly was, yet Sir Thomas Watson made such use of his powers and opportunities that no portion of his distinguished career can be said to have been occupied with the performance of other than valuable and permanently beneficial labours in behalf of the profession he so intensely loved. The noble traits of his character are rendered doubly dear to us, because we know the earnest devotion with which the interests of medicine were ever cherished by him, and because, in the share we have in common in the great legacy he bequeaths to science, we realise the incalculable importance of his constant efforts to raise and to improve.

The subject of this notice was born at Kentsbeare, in Devonshire, on March 7th, 1792. After leaving the Grammar School at Bury St. Edmund's, he proceeded to St. John's College, Cambridge, and in 1815 graduated with mathematical honours, being placed tenth on the list of Wranglers. The following year he obtained a Fellowship, and for some time subsequently he remained at Cambridge in the capacity of private tutor. In 1820 and 1821 he studied medicine in Edinburgh, and proceeded to the degree of M.D. in 1825, in which year also he resigned his Fellowship on marrying the niece of the Rev. Dr. Turner, Master of Pembroke College, and Dean of Norwich. Thenceforward Dr. Watson pursued the practice of medicine, settling in London with this object, and being elected F.R.C.P. in 1826. His first hospital appointment was held at the Middlesex Hospital, where in 1827 he became physician, a post he retained for fifteen years. As a practitioner, he was not at first peculiarly successful, and to his early troubles was added the intense grief caused by his wife's death in 1830, two children having been born to them in the interim. In 1831, Dr. Watson was selected as Professor of Forensic Medicine at King's College, at which place he subsequently (1836) received the appointment of Professor of Medicine, a post, however, resigned by him in 1840, when, on the foundation of King's College Hospital, he chose to maintain his connection with the Middlesex rather than leave that institution, in order to continue in possession of the chair he had filled with such incalculable advantage to medical science. It was now that his classical and incomparable lectures on the Practice and Principles of Physic were given to the world in a collected form, being first published serially, and subsequently as the volumes which are the most universally read and admired of any text-books in medicine.

The offices served by Dr. Thomas Watson at the Royal College of Physicians included every one of dignity and importance. In 1827 he was Gulestonian Lecturer; Lumleian Lecturer in 1830 '31; and College Lecturer on Materia Medica in 1833, '34, and '35; Censor in 1828, '37, and '38; and on numerous occasions a member of the Council. He was also the first representative of the College at the General Medical Council, on its creation in 1858, and held this post until 1860. It was in 1862 that he graced the Presidential Chair of the College of Physicians, and thus shed renewed lustre on the corporation which had for such a length of time enjoyed the best attention of his ever active mind. This post he retained five years in succession, and it was by his own conscientious refusal to keep it for a further period that alone hindered his re-election. The College, soon after his resignation of the Presidency, became possessed, by subscription, of an excellent portrait of the great physician it was their

delight and privilege to honour thus; and this memorial of the most illustrious of eighteenth-century doctors is now a cherished treasure in the College building.

In 1859 Dr. Watson was made Physician Extraordinary to Her Majesty the Queen, and in 1870 one of the Physicians in Ordinary. During the last illness of the late Prince Consort he was in constant attendance on the patient for some days, meeting in consultation Sir James Clark, Sir Henry Holland, and Dr. (now Sir William) Jenner. In 1866, by the Queen's express desire, the dignity of a baronetcy was conferred on Dr. Watson, who thenceforward took a less burdensome part in the practical departments of the profession, as befitting his advancing years. His last official connection with his profession was during the period from 1867 to 1869, when he sat as President of the Clinical Society of London.

The history of the venerable physician's last days is already familiar to our readers; suffice it to say that, after a long life exceptionally free from ailments, he was seized, on Sunday, October 22nd, with symptoms of paralysis, which, increasing in extent and significance, gradually brought him to a condition of increasing weakness, until, on Monday, Dec. 11, Sir Thomas Watson passed to his eternal rest.

One feeling only is ever excited by the mention of Sir Thomas Watson's name in those who are able to associate with it a recollection of his far-reaching and incalculable services to mankind—a feeling of reverent love and admiration. Attaining to such eminence as the greatest benefactors alone can hope to reach; receiving in unsurpassed amount the marks of distinction and honour accorded only to those whose deserts it is impossible to conceal; he yet pursued his way in life without creating a single enemy for himself, or a single detractor of his virtues or his deeds. From the Sovereign to the humblest reader of his immortal work, one and all combine to express affectionate recognition of his manifold claims to human gratitude. From one and all his memory receives the tribute that is given only to the noblest and the best of men.

Correspondence.

THE LATE DR. HANDSEL GRIFFITHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I desire your aid in my appeal on behalf of the three orphan children of the late Dr. Handsel Griffiths, of Dublin, aged respectively 8½, 5½, and 4½ years. Their father, who was a highly educated physician and surgeon, was author of many papers on materia medica and chemistry. Some of these works are well known—viz., "Posological Tables, Materia Medica, and Pharmacy," "Lessons in Prescribing," &c. He also occupied the positions of Assistant Librarian to the Royal College of Surgeons in Ireland and Lecturer on Chemistry in the Ledwich School of Medicine, Dublin. In both appointments he gave the utmost satisfaction, and was a particular favourite with all those whom he was brought in contact with. In the year 1877 he was suddenly struck down with an attack of typhoid fever, and having undermined his constitution, never a robust one, by continued mental labour in the day, as well as severe literary work at late hours of the night, he was unable to battle against the attack, and died on the fourteenth day of his fever, at the early age of 31, leaving a very delicate wife and two young children in very distressed circumstances. The third child was born two months after his father's death. The very week he took sick he contemplated effecting an insurance on his life to provide for his family. Two months ago his wife, who made a heroic struggle on behalf of her young family, succumbed to phthisis, and the little orphans are now wholly helpless, except for the aid they receive from an aged grandmother, who supports herself and them by the precarious mode of existence of letting furnished lodgings. To support and educate these children till they are able to help themselves is the object of a committee which has just been formed, and subscriptions sent to me or to the following will be thankfully received and acknowledged:—Rev. F. Carmichael, LL.D., 10 Sallymount Avenue, Leeson Park, Dublin; Rev. James H. Walsh, D.D., 18 Herbert Place, Dublin; Walter G. Smith, Esq., M.D., 34 Lower Baggot Street, Dublin; Kendal M. Frank, Esq., M.D., 69 Fitzwilliam Square, Dublin.

I am, Sir, yours, &c.,

LAMBERT H. ORMSBY, M.D., F.R.C.S.

4 Merrion Square West, Dublin, Dec. 18th, 1882.

PASS LISTS.

University of Oxford.—At a Congregation holden December 18th the degree of Doctor in Medicine was conferred upon the following candidates :—

Bonville F. Fox and Edgar O. Hopwood, Christchurch; Percy K. J. J. Balliol.

University of Cambridge.—At a Congregation holden December 18th the degree of Bachelor of Medicine was conferred on Adolphus Vaughan Bernays.

University of London.—The following candidates have passed the recent M.D. examination at this University :—

*Buckell, Arthur Edward.
Collins, William J. B. S. B. S.
Dalton, Norman.
Davy, Henry.
Dickinson, Thomas Vincent.
Edwards, Edward Joshua.
Firth, Charles.
Gabb, James Percy Alwyne.
Hobson, Lewis John, B.S.
MacDonald, Greville M. the son.
Maguire, Robert (Gold Medal).
Notley, William John, B.A.
Paddison, Edmund Howard.
Parker, Louis Colman.

Penny, Edward.
Petch, Richard.
Plumbe, Samuel Thomson.
Raitliffe, Thomas Carleton.
*Rake, Beaven Nave.
Routh, Amand J. McConnell, B.S.
Russell, George Hannah.
Saunders, George James Symes.
Savill, Thomas Dixon.
Sayer, Mark Feetham.
Squire, John Edward.
Stonham, Thomas George.
Suckling, Cornelius William.
Whittle, Edward George.

* Obtained the number of marks qualifying for the Medal.

Logic and Psychology only.

Bunes, George Frederick.
Buckley, Samuel.
Hayward, John Davy.

Neale, William Henry, B.S.
Sik, John Frederick William.
Taylor, Harold Glibertson.

The following have passed the M.S. examination :—
Ballance, C. A. (Gold Medal). | Collier, Mark Purcell May.

The following have passed the B.S. examination :—

First Division.

Collingwood, D. V. I.
Pike, Charles James.
Roedel, Waldemar Joseph.

Sutton, Samuel Walter.
Walters, Frederick Rufenacht.

Second Division.

Batterham, John Williams.
Boxton, Dudley Wilmot.
Campbell, Harry.

Clarke, Ernest.
Dak, William Radford.
Scharlieb, Mary Ann Dacomb.

University of Durham.—At a convocation held December 12th, the following degrees were conferred :—

M.D. (practitioners of fifteen years).—P. Colman, P. Cowe, E. Goddard, A. C. Ryner, and G. Thompson.

M.D.—A. W. W. Dowding, T. Dutton, A. Mantle, G. J. Pardington.

M.B.—D. H. Barley, F. W. Giles, P. Brown, J. Hartley, W. Sheppard, M. S. C. H. Milburn, W. Sheppard.

M.B. and Chir.—Rev. R. R. Furlong, Trinity College.

Royal College of Surgeons of England.—The following members of the College, having undergone the necessary examinations for the Fellowship at the half-yearly meetings of the Court of Examiners on the 23rd, 24th, and 25th ult., were reported to have acquitted themselves to the satisfaction of the Court, and at a meeting of the Council on December 14 were admitted Fellows of the College :—

W. Edgar Buck, M.A. and M.D. Cantab., Leicester.
Allen Dingley, L.E.C.P. Lond., Argyle Square, W.C.
A. Banks Prowse, M.D. Lond., Cambridge.
J. Ernest Lane, Norfolk Square, London, W.
R. Marcus Gunn, M.B. Edin., Park Street, London, W.
T. F. Hugh Smith, L.S.A., Wimpole Street, London.
P. Rufenacht Walters, M.B. Lond., Croydon.
James Hardie, M.D. Edn., Manchester (not a member).

King and Queen's College of Physicians in Ireland.—At the usual monthly examinations for the Licences of the College, held on Monday, Tuesday, Wednesday, and Thursday, December 4th, 5th, 6th, and 7th, the following candidates were successful :—

For the Licences to practise Medicine and Midwifery.—George Purcell Atkins, Cork Street Hospital, Dublin; Patrick D. Neillan, Castlereagh; George Henry Johnson Fisher, Rathmines, Dublin; Arthur Joseph Greene, Dublin; Robert Joseph Gubins, Killybeg, co. Limerick; Richard Hatch, Dublin; James Joseph Kerr, Meadow Bank, Sligo; Patrick Maguire, Arney, co. Fermanagh; Edward David Mullan, Londonderry; Michael James Nolan, Limerick; Rowland Pollock, Navan, co. Meath.

For the Licence to practise Medicine only.—John Leslie Barrington, Dublin; Edward Vernon, M.R.C.S. Eng., 1853, Kingston, Yeovil, Somersetshire.

For the Licence to practise Midwifery only.—John J. Austin, M.D. Royal Univ. Ire., Abghill; Alfred Wynter Hawthorne, M.D. Royal Univ. Ire., Dromore, co. Down.

The following Licentiates in Medicine of the College, having complied with the by-laws relating to Membership pursuant to the provisions of the Supplemental Charter of

December 12th, 1878, have been duly enrolled Members of the College :—

John Joseph Mullan, Licentiate 1861, Dandrum, co. Dublin; George St. George Tyner, 1863, Downpatrick; William Tobin, 1868, Halifax, Nova Scotia; John Byrne Power, 1-71, Kingstown, co. Dublin; Chas. Edward Geoghegan, 1874, Surgeon R.N.

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners, held on the 20th November and following days, the under-mentioned gentlemen passed the first half of their Examination for the Letters Testimonial of the College :—

Henry O. Beattie, James I. Bolger, John V. Byrne, Alexander E. Carte, Thomas F. Casey, Henry G. G. Day, Samuel R. D'ane, Edmund D. Denny, Patrick Duff, Thomas S. Griffin, Thomas G. Hall, Arthur J. P. Hogan, John Martin, Francis J. Maunsell, Hercules L. Milne, Henry Moorehead, Thomas H. Myles, Thomas J. M. O'Donnell, Edward G. Peters, Alfred J. S. Roe, George F. Rouham, A. Werberford Sheperd, James L. E. Somers, William R. Tomlinson.

The following gentlemen passed their First Professional Examination, in accordance with the New Regulations :—

Edward W. Hamilton, Augustus H. G. Johnston, William A. Johnston, and Richard B. McCausland.

Notices to Correspondents.

66 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 28 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. F. A. S. (New York).—Sorry we cannot further aid to our already over-full exchange list.

PEAT AS A DRESSING FOR WOUNDS AND OPERATIONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In the October number of your valuable journal, page 366, the use of peat as a dressing is ascribed to Dr. Neuberg. In the *Lancet* of February, 1872, page 162, a paper by Dr. Howell describes the great value of this mode of dressing; and a reference to "peat" in the "Medical Digest" will further testify that its value as a disinfectant has long been appreciated.

Yours obediently,

South Hampstead, Dec. 11th. RICHARD NEALE, M.D. Lond.

MR. SAMSON LEE.—There are several modes suggested for staining the bacilli, and by referring to the journals of the past few months you will find the details of manipulation and preparation fully described and discussed. You cannot obtain any results by examination, except with the assistance of much higher powers than you possess. A 1-6th or 1-8th object-glass at least must be employed.

A. R. E.—"The Practice of Physic" is now in its fifth edition, having been last published in 1871. The anecdote you refer to in connection with it is substantially true; nor is there any reason to suppose it should be an invention.

LOUIS.—Morton's Iodo-glycerine fluid was introduced by Prof. Jas. Morton, of Glasgow, who published the first successful cases of spina bifida treated by it. The formula recommended by Prof. Morton is as follows :—

R Iodine, gr. x ;
Potassii Iodidi, gr. xxx ;
Glycerine, ℥j. Misco.

The fluid is injected into the tumour, a small amount of the contents of the latter being first evacuated. This provision, however, is not received with general favour; but Dr. Morton claims to have cured seven cases out of ten by his method.

CANDIDUS.—Sulphate of barium has been recommended as a substitute, and has been employed in this connection with considerable success. It is quite innocuous.

A LARGE CHILD.

DR. ADALBERT VYSIN, of O'mütz, reports (*Wien Med. Presse*, Dec. 1882) the birth of a child 9.8 kilog. in weight (21½ lb avoirdupois). The presentation was breech, and the head could not be extricated in sufficient time to save its life. The sex is not stated.

DR. SCHNEER (Carlsbad).—Sorry we cannot oblige you by making the announcement; it is unusual in the higher class of professional journals in this country.

B. B. says: I am medical officer to a workhouse, but have not the poll a. Could I make the police authorities pay me for my attendance on those sent into hospital?

[Under Sec. 4 of Poor Relief Amendment Act, 25 and 26 Vic., cap. 83, the guardians are not empowered to charge "any poor person requiring medical and surgical aid in hospital" anything

more than "such proportion of his or her maintenance while in hospital" as the guardians may consider reasonable. No provision is made for medical fees, and in no case is the sum payable to exceed "the average of the general cost of maintenance, medical and surgical treatment in such hospital." Therefore, at best, the guardians could only charge the patient with a few pence or shillings paid by them to the doctor. There is, in fact, no relief for the medical officer under the circumstances.—ED.]

DR JENNINGS (London Hospital).—We much regret that, owing to pressure on our space by Sir James Paget's lecture and other communications, we are unable to insert your paper on "Transfusion for the Hemorrhages of Parturition" in the present number as we had hoped.

DR W. H. CULLEN (Cyprus).—Thanks for note; the information will be acceptable.

MR. SHANN (York).—We are at all times glad to receive notes of society proceedings and clinical cases when they contain matter of practical interest to practitioners.

SENEX.—Your question needs thought and inquiry, and will be answered next week.

REGISTRARSHIPS IN IRELAND.—"Biceps" asks: 1. Can the Irish Registrar-General justify his refusal to appoint the medical officer of the dispensary district registrar of deaths, births, and marriages when there is nothing to disqualify said officer for the office? 2. What course would you recommend to a medical officer refused for the appointment? 3. Has the Lord-Lieutenant anything to do with the appointment of registrar of deaths, births, and marriages?

[1. The medical officer of the dispensary district, says the Act, "shall be the registrar of births, deaths, and marriages if he shall think fit to accept the office, provided he possesses the qualifications which the Registrar-General declares necessary." Moreover, though, by this law, it is open to a newly-appointed medical officer to decline the Registrarship, it is usual for the Local Government Board to force him to accept the office by refusing their sanction to his appointment if he does not state his willingness to act in such capacity. If, however, the office has not been previously held by the medical officer, and is not vacant at the time when the new officer is appointed, then the latter officer must wait until the appointment becomes vacant, as the holder of it cannot be unseated for the new comer's benefit. 2. We cannot advise until we know the special circumstances as indicated above. 3. No.—ED.]

MR. R. D. (London).—Pressure on our space compels us to hold over your communication. We have added a quarter sheet to the present number; but the demands upon our space are greater at this season than we can meet. We hope to refer to it in the first number of the new year.

A STUDENT'S DIFFICULTIES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Having read with interest and advantage your Students' Number for 1882, I will ask you to kindly reply to the following questions:—I am a registered matriculated R.I.U. student—sober and industrious. I am taking lectures in Anatomy, Chemistry, Botany, and Zoology. I want a cheap degree in Arts and Medicine. The Natural History Professor here was not appointed till some days since. If I regularly "pound" for Anatomy and Dissections, as well as Chemistry, Natural History, and the first examination in Arts, I'll be (I fear) like the boy and the nuts, and will ruin my weak health. When I have passed the R.I.U. first examination in Arts, I shall defer the remaining examinations for B.A. till I am M.B. I am taking Latin and French next time to shorten my first professional examination.

Queries.—(a) Ought I merely put in formal attendance in Anatomy and Dissections, as *here*, till the end of your third year, you must attend the junior classes in both, and study the Arts, and Zoology, and Botany?

(b) If so, would the *Invertebrata* be more easily "made up" in such short time than the *Vertebrata*?

(c) Would Dr. M. A. Ward's (Fannin and Co.) "Zoology and Comparative Anatomy Outlines" pass me in the R.I.U., or what would?

N.B.—I am convinced that nothing but "cramming" will ever pass a man in Zoology and Anatomy.

(d) If you'd forbid me to forsake Anatomy for this year, would you advise me to study (with my brother) for St. Andrews University?

(e) If so, ought the same zoological text-book (Dr. Ward's) pass me there?

Yours obediently,
TYRO MEDICUS.

[(a) You had better pay moderate attention to Anatomy and Dissections, without which you could not attain a competent knowledge of Zoology. Your great point, however, should be (for the R.I.U.) your first examination in Medicine, in which you will have to answer in Botany, Zoology, Physics, and French.—(b) Cork College has always been an institution of rather "Invertebrate" tendencies. You would make up the "Vertebrata" more easily in the short time.—(c) Dr. M. A. Ward's manual on "Zoology and Comparative Anatomy" would be quite insufficient for the "Royal." Use Nicholson's "Manual of Zoology" as a handbook; and Huxley on "The Vertebrata" as a reference. The Zoological and Botanical Examinations are now so searching, so practical, and so full of natural specimen questions that cramming is literally "nowhere;" and the same may be said of examinations in Anatomy. Unless you are thoroughly conversant with these two branches, do not waste even train-fare in endeavouring to pass. In Zoology you will find great aid in the Zoological Museum of

Cork College, which is one of the finest and best-arranged that we have seen. It is two years since we were conducted over it by the President, and it has been since improved.—(d) The question of the St. Andrews degree must be left to your own consideration. It is a second-class qualification; and even this is a very charitable view. Dr. Ward's manual will be more than sufficient for that examination.—ED.]

MEETINGS OF THE SOCIETIES.

ACADEMY OF MEDICINE IN IRELAND.—Friday evening Dec. 2nd. Business: Address by the President of the Obstetrical Section, J. Denham, Esq., M.D.—Living Specimen: Mr. Arthur Benson, A Case, showing a Recent Spontaneous Detachment of the Retina, with a well-defined rent in its structure.—Specimens exhibited by Card: Dr. J. S. Poole, Double Ovarian Dermoid Cysts, removed by Dr. Kidd.—Mr. F. S. Abraham, Microscopic Sections of same Cysts.—Dr. Neville, Two Cases of Foto-anomalous Adhesions, with resulting Deformities.—Papers: Dr. More Madden, "On a Case in which Occultation of the Vagina followed on Parturition."—Dr. W. J. Smyly, "On a Case of Induced Abortion."—Dr. Neville, "On the Breaking Strain of Umbilical Cords, with remarks on Traction upon the Cord as a cause of Inversion of the Uterus."—Notice.—Exhibition cards may be had from the Secretaries. Titles of Papers, and, if possible, the necessary particulars of any objects to be exhibited by card, are to be sent to the Sectional Secretary at least one week before the meeting of the Section. Fellows or Members may introduce two visitors by cards obtained from the Sectional Secretaries.—WM. C. NEVILLE, Sectional Secretary; WM. THOMSON, General Secretary.

Vacancies.

Chipping Norton Union.—District Medical Officer. Salary, £65, with the usual medical fees. Applications to the Clerk on or before Dec. 25th.

Hospital for Consumption and Diseases of the Chest.—Resident Clinical Assistants. Applications to be sent to the Hon. Sec., at the Hospital. (See Advt.)

Royal Free Hospital, London.—Junior Resident Medical Officer. Board and residence is provided, but no salary. (See Advt.)

St. Mary's Hospital, Paddington, W.—Physician. Applications to be sent to the Secretary on or before Dec. 30th.

University of Edinburgh.—Examiner in Medicine in each of the Departments of Chemistry, Anatomy, Midwifery, and Practice of Physic. Applications to be forwarded to the Secretary not later than Jan. 15th.

University College, London.—The Jodrell Professorship of Physiology. An endowment (of the value of £264 per annum) is attached. Applications will be received on or before Jan. 24th.

Weston-super-Mare Hospital and Dispensary.—House Surgeon. Salary, £70, with board, &c. Election, Dec. 23rd.

Appointments.

BATTERHAM, J. W., M.R.C.S., B.Sc. Lond., House Surgeon to the Wolverhampton and Staffordshire General Hospital.

BAKER, H. F., F.R.C.S. Ed., Surgeon to the Cripples' Nursery, Park Place, Clarence Gate.

FOWLER, C. O., M.R.C.S., Assistant Resident Medical Officer to the London Fever Hospital, Islington.

HOPE, E. W., M.B., B.C. Edin., L.R.C.P., House Physician to the Wolverhampton and Staffordshire General Hospital.

JONES, C. L., M.D. Dub., M.B. Cantab., Public Vaccinator for Christchurch and St. Saviour's District, St. Saviour's Union.

KENNEDY, Dr., Medical Officer to the Carlingford Dispensary, Dundalk Union.

MOODY, J. M., M.R.C.S., L.R.C.P. Ed., Medical Superintendent of the Surrey County Asylum, Cane Hill.

WILLSON, H., M.R.C.S., Medical Officer for the Christchurch District of St. Saviour's Union.

Births.

CULLINAN.—Dec. 12th, at Ennis, the wife of William Cullinan, Surgeon, Clare Co. Infirmary, of a son.

IRONSIDE.—Dec. 13th, at 8 Highbury New Park, the wife of R. A. Ironside, M.B., C.M., of a daughter.

Marriages.

NICHOLSON—RODDAM.—Dec. 12th, at St. Mark's, Woolston, Southampton, James Edward Nicholson, Surgeon, Army Medical Department, to Adelaide Roddam, granddaughter of the late Roddam J. Roddam, co Northumberland.

Deaths.

ALLEN.—Dec. 15th, at Merriam, Gorey, of congestion of the lungs, John Burgess Allen, M.D., aged 52.

BOUGLAS.—Dec. 9th, at Carlisle, James Bouglas, L.F.P.S. Glas., aged 84.

CLAYTON.—Dec. 15th at his residence, Corrib View, Galway, Nicholas Clayton, M.D., of typhoid fever, aged 86.

EBSWORTH.—Dec. 12th, suddenly, from congestion of the lungs, at 11 Collingham Place, South Kensington, Alfred Ebsworth, F.R.C.S.E., aged 61.

LAWRENCE.—Nov. 30th, at 31 Claverton Street, Bath, George Edgar Lawrence, M.R.C.P. Lond., M.R.C.S., aged 32.

SMITH.—Dec. 14th, at 42 Park Street, Grosvenor Square, W., after a short illness, Sarah Anne, wife of Protheroe Smith, M.D.

WATSON.—Dec. 11th, at Reigate Lodge, Surrey, Sir Thomas Watson, Bart., M.D., aged 90.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 27, 1882.

RETROSPECT OF THE YEAR 1882.

England.

INTRODUCTION.

It will probably be long ere it falls to us to chronicle the history of a year in which so many events of moment to the profession of medicine took place as occurred in 1881, for the ever-memorable Congress which was held in London during it must necessarily continue to rank as the most important medical occurrence of recent times. Notwithstanding this fact, however, the year now fast closing in has been fairly productive of advances in professional matters, so that a survey of the progress accomplished within it will afford satisfactory evidence of successful activity in all the departments of research and practice. Among the occurrences of more general interest to the profession which serve to mark 1882 in any special manner, are several that will significantly influence the position and performances of medical men in the not very distant future. And the purpose we have in view will perhaps most suitably be accomplished by following the same course formerly pursued in drawing up our annual Retrospect, in which politico-social subjects, and those having a less distinctly special bearing on medicine or surgery, have been considered in the opening section of the work. In this way we will draw attention first of all, as being of chief importance in this respect, to

THE REPORT OF THE ROYAL COMMISSION ON THE MEDICAL ACTS.

This anxiously anticipated document was published about the end of June, and its principal items include a recommendation of many of the measures so persistently advocated in our columns as essential for securing equable and sufficient qualification of practitioners in all three divisions of the United Kingdom. The Report advises that registrable qualifications shall in future be granted by a "Divisional Board" in England, Ireland, and Scotland respectively, all three being under the control of the General Medical Council; but the mistake has unfortunately been made of suggesting that while a common curriculum and standard should be main-

tained in the three countries, the question of *fees* should remain to be decided locally. This proceeding necessarily will tend to encourage the Scotch corporations in the course of underselling, which they have found too profitable for it to be expected they will readily decline to discontinue; indeed, we hold most emphatically that the basis of absolute uniformity in every respect throughout the kingdom is that alone in which it is possible that advantageous results from importing changes into the mode of conferring qualifications can be expected. The Report is remarkable from the fact that there are appended to it no less than seven supplementary reports, all more or less dissenting from its conclusions, and all emanating from members of the Commission. Direct representation on the Medical Council is vigorously protested against by Mr. Turner, Mr. Simon, and Mr. Sclater Booth, while Professor Huxley and Bishop Magee urge the abolition of existing licensing bodies, and the institution of a "Staats Examen" on the German model. In the discussion which the proposals will undergo in the House of Commons, however—aided as it will be by the criticism already given to the Report—it is to be confidently hoped that its objectionable features will be so far modified as to reduce them to conformity with general professional opinion. That consideration will be given to the question of medical reform in the next Parliamentary session, some prospect was afforded to a deputation which recently waited on the Home Secretary with the object of obtaining a promise to this effect; and we trust that our next Retrospect may be partly devoted to the pleasing task of describing the introduction and scope of urgently needed measures of reform in the medical profession.

THE GENERAL MEDICAL COUNCIL

Held its usual annual meeting in July, the session being unduly protracted by reason of the discussion to which the report on the visitation of examinations was submitted. This report is the combined

production of Mr. T. P. Teale, Dr. Gairdner, and Mr. Stokes, and contains descriptions of, and reflections on, all the non-university examinations conducted in the United Kingdom for testing the knowledge of candidates for medical and surgical qualifications. The conclusions of the Visitors, having been laid before the authorities interested, elicited replies from the latter not always appreciative of the spirit in which the observations were carried out. For many days the Medical Council wearied itself and its audience with purposeless quibbling over the strictures passed upon its own deputies, and eventually accepted the recommendation of the Visitors so altered as, in effect, to meet the principal objections urged against them in their original form. These mainly referred to the performance of actual dissections by candidates at anatomical examinations, and of operations on the dead body at final tests for qualification in surgery.

Of other work the Council did little of any importance, except first to convict a duly registered practitioner of unprofessional conduct, and then at once proceeded to acquit him from undergoing any form of the punishment it has the power to inflict. Subsequently, with a fine absence of any sense of the ludicrousness it exhibited, the Council appointed a committee from its own body to consider and report on the unqualified assistant system, presumably that it might thus devise an opportunity for glorifying its own encouragement of the practice as shown in its treatment of offenders in this direction.

Several changes in the *personnel* of the Council have occurred in the interval between its meetings in 1881 and 1882. Thus, Dr. King Chambers replaced Dr. Rolleston, deceased; Dr. Patrick Heron Watson took the seat left vacant by the death of Mr. Spence; Dr. Lyons that occupied for so short a time by Dr. M'Clin-tock prior to his removal by death; and Mr. Marshall Sir James Paget's place as representative of the Royal College of Surgeons.

In the way of general usefulness the Council has shown no improvement whatever.

REGISTRATION OF MIDWIVES.

The evil consequences so frequently arising from the ignorant interference of so-called midwives in cases of labour having been again and again indignantly commented upon both in the press and by private individuals, the question has been energetically taken up by a powerful committee, which is now making strenuous efforts to obtain the passing of a short Act of Parliament making it a criminal offence for any unlicensed and unregistered woman to take on herself the office of midwife. Clauses are introduced into the draft Bill providing for the creation and maintenance of a "Midwives' Register" under the supervision of the General Medical Council, and for local examination of candidates for registration in the elementary outlines of midwifery practice. A deputation of those interested in the measure was received by the Medical Council at its summer meeting, and the matter was, at a later stage of proceedings, discussed in Council on the presentation of a report from a committee

appointed to consider it, with the result that the Council gave a general approval to the scheme. Since then no further public announcement as to the progress of the movement has been made.

THE ADVANCEMENT OF RESEARCH.

A highly important movement, set on foot in 1881, and having for its object the promotion of scientific medicine through research, has assumed in the past year a position of the utmost influence by reason of the number and eminence of its officers and members. The new society holds its meetings at the Royal College of Physicians of London, and includes in its ranks every British biologist of note—lay as well as medical. Its president is Sir William Jenner, and the Council is a most representative and powerful body of scientific inquirers, to whom may be safely entrusted the protection of scientific interests in the future. Much of the work to be accomplished by this Association is necessarily of a propagandist description, the diffusion of truths concerning the experimental study of physiology and the benefits it confers on the progress of medicine and surgery, being a principal aim with it. Some progress has already been made in this direction by the publication, in a cheap and elegant form, of a number of addresses on the value of vivisection given, from time to time, by Prof. Humphry and others; and much more may be expected of the Society, both of this particular kind of labour, and of more material assistance on behalf of harassed experimentalists, whose efforts in the cause of discovery are at present hampered by the miserable restrictions imposed by the Vivisection Act. It need only be added that the Association is receiving very liberal support, moral as well as pecuniary.

THE SMALL-POX COMMISSION REPORT.

During the autumn the Royal Commission on Small-Pox Hospitals presented their report, drawn up after hearing the evidence of a very large number of witnesses; and concurrently there appeared a valuable contribution on the same subject, in the shape of the tenth annual report of the Local Government Board, to which was appended a supplement containing reports and papers submitted by Dr. George Buchanan on the Use and Influence of Hospitals for Infectious Diseases. The result of these important inquiries will be such amendment and improvement of existing modes of dealing with infectious sick persons as will probably remove many of the dangers to which they have undoubtedly given rise in the past. Isolation is imperatively insisted on by all competent witnesses, and one very striking result brought out in the report is, that the influence exerted by hospitals for infectious diseases is certainly exercised in increasing degrees over the surrounding districts in proportion as these approach more nearly to their centre. The main effect of the whole series of examinations has yet to be made evident by the enactment of legislative measures, to which, therefore, we must look to see the suggestions enumerated carried out.

BRITISH MEDICAL ASSOCIATION.

The British Medical Association this year held its

jubilee meeting in the city of its creation, Worcester ; and the occasion was appropriately recognised by the presentation, on the part of the Association, of a bust of its founder, Sir Charles Hastings, to the city of which he was a native. As might have been expected, the meeting was unusually successful, and the Presidential addresses were marked by especial excellence, particularly those of Dr. F. W. Wade on Medicine ; of Professor Stokes on Surgery ; and of Prof. Humphry on Physiology. Some excitement was created by the knowledge that Dr. Milner Fothergill had given notice of a motion in reference to the mode of election of officers of the Association, but in consequence of his absence when called upon to state his resolution, the matter dropped through. In the way of work, the meeting was eminently successful, a large number of papers being contributed, with a greater proportion than usual even of such as were of a permanently valuable nature. Several very pleasant excursions were made to localities of interest around and near Worcester, and altogether the jubilee ranks as an important gathering of the Association.

TUBERCULOSIS.

Early in the year publication was given to Koch's researches on the Etiology of Tuberculosis ; and ever since the air has been rife with controversies on this subject. According to the results obtained by Koch, tuberculosis is an infectious disease, the element of which is a minute organism to which he assigns the name *bacillus tuberculosis*. This he never failed to find in the pulmonary excreta of phthisical individuals ; and by cultivating it in appropriate fluids, was enabled to reproduce it almost indefinitely, with the result that even the most distant generation of bacilli derived from an infective mass could produce, when injected into animals, the typical symptoms and deposits of tuberculosis. The modes of experimenting and of staining the microscopic organisms have been rendered universally familiar to all readers, and have been repeated very extensively not only in Germany and France, but also in this country and America. Koch's conclusions, however, are by no means generally accepted, and numerous objections have been raised against his interpretation of facts which all agree in observing. In America, opposition is raised by Dr. H. C. Formad, whose researches into the nature of diphtheria entitle him to be heard with favour. According to him, tuberculosis is a disease peculiar to individuals in whom a special anatomical condition of connective tissue exists, the chief difference between them and normal bodies being the narrowing of the lymph spaces. He concludes, also, that certain animals, which he terms the scrofulous class, are naturally subjects of such anatomical structure, and as it was in such animals that Koch's experiments were conducted, his theory is thus far supported. He claims also that the tuberculous infective material of Koch may be developed in such animals by the irritation of any foreign body—*e.g.*, chemically clean glass in powder, when introduced into the peritoneal cavity or elsewhere, and therefore the conclusion is formed that bacilli are a result—and by no means a cause—of tuberculous inflammation.

In recent numbers of the *Practitioner*, Prof. Burdon

Sanderson has republished a series of experiments conducted as long ago as 1868, from which conclusions not entirely unlike those formulated by Dr. Formad may be deduced, and which must at least tend to modify the ardour of unhesitating participators in Koch's explanation of the phenomena he has so carefully described.

At present, therefore, the question remains *sub judice*, but whatever the ultimate determination arrived at may be, there can be no doubt of the immense importance of the discussion excited by the startling propositions out of which they have originated. Not only has attention been forcibly and widely drawn to the study of phthisis from the most remunerative side—that of causation—but a stimulus has been given to original research which will assuredly bear fruit a hundredfold in more than that branch of medicine to which it has been primarily directed.

Not a little harm, also, has been done by the "scare" which pervaded the world on publication of the supposed infectiousness of consumption. Among the unreflecting the idea at once seized hold, and as a consequence much trouble and pain have been very unnecessarily created. In Germany matters have even gone so far as to lead to isolation of tuberculous patients in some hospitals ; and if the fears of many persons here were consulted, there is little doubt that similar measures would be followed out in this country. At present, however, there is much more reason to suspect that the theory of infection is underproven ; but none the less it will long be remembered that the year 1882 was that in which the first attempts at exhaustive investigations into the real nature of the disease were undertaken.

MEDICINE.

The year's progress in medicine has been marked by no very startling innovations, but, nevertheless, a steady advance has been manifested in the direction of improved modes of treatment and exhaustive study of disease, the consequences of which are necessarily not always quite immediately noticeable. The chief interest in this connection has naturally been excited by discussion of the bearings and applications of such discoveries as relate to etiology and therapeutics, and particularly in connection with the developments following on such researches as those of Koch, Pasteur, Sanderson, and their imitators. An important contribution to this division of knowledge is to be found in the Lumleian Lectures delivered in April before the Royal College of Physicians, by Dr. J. Burdon Sanderson, on

THE PATHOLOGY OF INFLAMMATION.

In this course of three addresses, Dr. Sanderson fully discussed the whole question of inflammation ; and while his conclusions may to a considerable number of persons seem at variance with received opinions, yet they are in every case so carefully considered and completely sustained, that no hesitation as to their universal acceptance can be entertained.

The first lecture was in great part historical and re-

capitulatory, and presented the thesis that the essential nature of inflammation is that it is a *damage*; thus rejecting the opinion that it is a modification merely of natural processes. The injury involves arrest of function in the injured part, the degree of arrests being determined by the extent of injury. Stasis is the primary factor in producing the damage, the necrosis thus initiated serving as the starting point for further pathological changes. It, however, and its attendant processes, vascular dilatation and exudation of coagulable lymph, are all stages in the destructive process. The real result of inflammation must be traced from the occurrence of actual stagnation in the vessels, a change in the condition of, or damage to, the latter being the excitant of the phenomenon. Redness, heat, and swelling may be produced without the injury exciting them being sufficiently grave to induce stasis in the vessels of the parts; and in such cases only a transitory effect is produced.

In the second lecture Dr. Sanderson discussed the influence exerted over the inflammatory process by micro-organisms, as proven by experiments. These minute bodies can now be regarded as no more important agents than *carriers* of infection. The conclusions arrived at in this connection are so important and so well borne out, and, moreover, their relation to what is a principal event of the year—viz., the tuberculosis controversy—that it is desirable to recapitulate them once more. They are thus summarised:—(1) In ordinary, normal inflammation the exudation liquid is not infective, and it may be re-absorbed in very large amounts even without undue effects being traced to its presence. (2) Neither air nor water usually contains inflammation-producing agents; consequently, these bodies may be injected, even in large amounts, into absorbent cavities in animals without setting up inflammatory changes—so long as the amount thus introduced is continuously absorbed. Damage and inflammation result, however, when the rate of injection exceeds the rate of absorption, a foreign body thus remaining to excite injury to the tissue. From this state transition to an infective condition is speedy, thus illustrating that (3) chemical change in the exudation liquid of inflammation renders the latter infective. The conclusion that these infective changes are due to the introduction of microzymes is inevitable if we accept the germ theory in explanation; and also that then they act as carriers of infection by circulating in the ordinary vascular channels. Even the chemico-physical theory of infection, however, would be equally applicable as a solution of the *modus operandi*; and, anyway, the factors combining to produce inflammatory changes remain unaffected.

The non-necessity for invoking the vaso-motor nervous system as an aid to vascular changes in describing the phenomena of inflammation and accounting for their production, and the demonstration of inherent powers of rhythmical contraction possessed by the vessels, are among the most interesting results dwelt upon by Dr. Sanderson; and while referring those wishful to follow his disquisitions further to the lectures themselves, we must repeat that for many

reasons their delivery will rank in the future as not by any means the least noteworthy of the events of 1882. In this place, also, it will be right to mention the observations on

THE FORMATION OF FIBRIN

which have been recorded by Dr. Richard Norris, professor of physiology at Birmingham, and an account of which is contained in a valuable monograph published by him a few months ago, on *The Physiology and Pathology of the Blood*. Dr. Norris was led, in 1875, to commence a long series of investigations into the nature of the blood corpuscles by the announcement that a newly discovered solid body, hitherto unnoticed, had been observed in the circulating fluid. Bringing to his aid an extensive acquaintance with pathological and physiological facts and methods, he set vigorously to work to find the bodies described, and to render them visible to others pictorially. This has been effected with the utmost distinctness and beauty by means of micro-photography, combined with delicate manipulation of the specimens of blood examined; and in the work referred to above, an extensive series of photographic plates gives accurate representations of the various conditions and changes in the corpuscular bodies detailed in the body of the book. In addition to affording indisputable proof of the existence of the third element of the blood, Dr. Norris offers evidence to show that fibrin is the result of abnormal deviations of this newly discovered element, which is, in fact, the cause of all descriptions of coagulation. We do not purpose here to enter into any discussion of Dr. Norris's conclusions, concerning which and the priority he claims for his observations an Italian physician, Dr. Bizzozero, has put forward counter-demands; nor can it be said that the significance attached by Dr. Norris to the newly discovered cells is universally accepted, they being regarded by him as having direct relations on the one hand with the red discs, and on the other with lymph and splenic corpuscles. The whole matter must become subject for careful consideration in the immediate future; but, as of very great pathological importance it is fully deserving of being chronicled in our record. Mrs. Ernest Hart, also, has published an interesting monograph on the blood, which will well repay perusal.

LECTURES.

The annual courses of lectures delivered during the year, have been fully as interesting and instructive as any that preceded them; and have been the means of adding considerably to the stores of valuable knowledge on various subjects accessible to the inquirer. Dr. Burdon Sanderson's Lumsian Lectures on Inflammation have been already sufficiently referred to. The course given by Sir Joseph Fayrer, as lecturer on the Croonian foundation, the subject being "The Climate and Fevers of India," was characterised by the varied learning and great knowledge of their author, whose long experience as a physician in India, moreover, lends unusual value to these lectures. The exhaustive discussion on which Sir Joseph Fayrer entered, in regard to malarial fevers and their etiology, will be turned to again and again with increasing

pleasure and profit by students of medicine of all ages and shades of experience; and none will fail to gain from it not only useful hints, but solid information and suggestions that will avail him much in the professional business of his career.

As lasting additions to medical knowledge, also, the Gulstonian Lectures by Dr. William Ewart, on "The Origin and Growth of Pulmonary Cavities," will long hold a place in literature; and though their author has abstained, in them, from entering to any extent on the question of treatment, he has yet brought together and contrasted such a mass of observations and demonstrations as materially tend to assist practitioners in their efforts to assist Nature's reparatory efforts. They should be widely and carefully studied.

We may here mention also, a single lecture on "The Contagiousness of Pulmonary Consumption," delivered by Dr. J. Burney Yeo, in King's College Hospital, soon after the general discussion on phthisis was provoked by Koch's discoveries. Dr. Yeo, from the outset of the controversy, has ranged himself on the side of the infectionists, and has, on several occasions, publicly demonstrated *bacillus tuberculosis* obtained by himself from the sputa of tuberculous patients. As a statement of a case *pro* infection, the lecture is interesting, and as a contribution to science is equally so; while the brief historical survey it gives of the growth of opinion on the subject it discusses it will be found very useful. Dr. Yeo thus formulates the propositions he undertakes to prove, or when proof is wanting to substantiate by clear evidence.

- (1) Tubercle is an infectious malady, originating in a specific virus, and propagated by the conveyance of that virus from body to body, and originating in no other way.
- (2) The specific virus of tubercle consists of a particular micro-organism, found only in tubercle; this organism can be seen in the cells of tubercle, can be obtained in a separate form, and cultivated in successive generations without losing its original properties.
- (3) Certain forms of disease, termed "scrofulous," are essentially tuberculous; and their characteristic, anatomical, morbid products contain the infective organism peculiar to tubercle.
- (4) The disease known as pulmonary consumption is, in the main, a tuberculous disease, and is dependent on the presence and propagation in the body of the infective organism characteristic of tubercle.
- (5) Pulmonary consumption is a contagious malady.

It is needless to say that these conclusions, though maintained with considerable skill, are by no means accepted by every one, or indubitably demonstrated. In previous notes the objections to them have been briefly indicated; but, as before observed, the controversy occupies a foremost place in the events of 1882, and must, consequently, receive a corresponding amount of notice.

At the Royal College of Surgeons Mr. Jonathan Hutchinson, F.R.S., delivered a deeply interesting and highly important series of six lectures on "Temperament, Idiosyncrasy, and Diathesis in Relation to Surgical Disease," to which reference may here be made. They were fully reported in our columns at the time.

HYPERPYREXIA.

In 1879 a committee of the Clinical Society was nominated to investigate the causes, consequences, and treat-

ment of hyperpyrexia in rheumatic fever and other acute febrile diseases; and in May last they presented a report on the subject, in which the following general conclusions were expressed:—

1. Cases of hyperpyrexia in acute rheumatism appear to prevail at certain periods, having in the last decade been remarkably numerous in the years 1873-76, whereas latterly they appear to have been much less frequent. Such excess corresponds in a certain degree, but not in actual proportion, to a similar excessive prevalence in acute rheumatism generally. The largest number of cases of hyperpyrexia arose in the spring and summer months, whereas rheumatism is relatively more common in the autumn and winter.

2. Whilst very little difference obtains between the two sexes in regard to proclivity to rheumatism, the proportion of males to females exhibiting hyperpyrexial manifestations is 1·8 to 1. But as to age no such marked difference exists; nor as to occupation.

3. The subjects of hyperpyrexia show no undue rheumatic tendency as regards family predisposition.

4. The cases of hyperpyrexia preponderate in first attacks of rheumatic fever.

5. Hyperpyrexia is not necessarily accompanied by any visceral complications, but may itself be fatal. The complications with which it is most frequently associated are pericarditis and pneumonia.

6. The mortality of these cases is very considerable, hyperpyrexia being one of the chief causes of death in acute rheumatism.

7. Although present in a certain number of cases, and these of much value from their prodromal significance, neither the abrupt disappearance of articular affection, nor the similarly abrupt cessation of sweating, is an invariable antecedent of the hyperpyrexial outburst.

8. The supervention of delirium or other symptom of nervous disturbance is very frequently either antecedent to or simultaneous with the hyperpyrexia.

9. There is considerable variability in the date of the occurrence and in the duration of the hyperpyrexial condition, ranging, according to our observations at least, from the fourth to the thirtieth day.

10. When death results, it has occurred mostly in the second and third weeks of the rheumatic attack.

11. The post-mortem examinations in a certain proportion elicited no distinct visceral lesions; and when present, the lesions were not necessarily extensive.

12. The prompt and early application of cold to the surface is a most valuable mode of treatment of hyperpyrexia. The chances of its efficacy are greater the earlier it is had recourse to. The temperature cannot safely be allowed to rise above 105°. Failing the most certain measure—viz., the cold bath—cold may be applied in various other ways: by the application of ice, by cold affusions, ice-bags, wet sheets, and iced injections.

SURGERY.

In many respects the surgical record of the year reads more eventfully than the history of medical progress, from whatever cause this may arise. Whether it is that inducements to resort to operative interference in desperate cases

are to be accepted as encouragements to skilful surgeons, or that occasions calling for unusual proceedings on the part of operators are really of numerous occurrence, it does undoubtedly strike one that cases of interest and importance from a surgical point of view are less rare than similarly unusual medical cases. In past years, too, the rapid advances which have been made in the path of instrumental improvements have been of a kind to arouse a feeling of security in the breasts of operators to whose use instruments of so great precision are introduced; and we may perhaps safely attribute some part of the certainly more intrepid performances of the present time to this cause. When all this has been duly admitted, however, the prime cause of recent advances still remains unmentioned, and that is the indescribable security conferred by the precautions in respect to perfect cleanliness which have been introduced on all hands as a consequence of the Listerian agitation. Even those who declare themselves to be non-antiseptic operators, are in reality that which they profess not to be; and Mr. Lister's objection is admissible that non-antiseptic surgeons by the absolute cleanliness of their method and the care they observe in securing freedom of all wounds from foreign material, do in effect carry out every precaution of Listerism with the omission only of its least important element, the spray. And one of the essentials of such treatment, by whomsoever carried out, is a reliable ligature, a preparation on which Mr. Lister has spent much time and thought.

LIGATURES.

In his Presidential address to the Clinical Society of London in 1881, Mr. Lister announced that he had perfected a mode of preparing catgut for ligatures by which he obtained what then seemed a very reliable substance, the method employed being to soak the gut in a watery solution of chromic and carbolic acids. In March last, however, he gave expression to the disappointment he had experienced when using such ligatures, the thicker ones being quickly infiltrated in place of being eroded. Further inquiries and careful experiments led him to associate the faults complained of with details in the manufacture of catgut; and following out the line of experiment suggested in this connection he finally obtained a ligature free from the defects of the chromicised substance. To this end the catgut is first steeped for twelve hours in one per cent. solution of chromic acid, and then in a solution of sulphurous acid, B.P. strength, for the same space of time. This material can be stored dry, but before being used should be steeped in a watery solution of carbolic acid. It is, Mr. Lister asserts, conveniently adapted to all the purposes of a ligature, and the drawback of infiltration has not been in any case observed during its use.

Mr. Barwell's advocacy of animal ligatures has induced many surgeons to emulate his remarkably successful achievements, and not by any means with unfavourable results. The want of success which has attended their employment in certain cases, however, led Dr. John A. Wyeth, of New York, to search about for a smoother and stronger animal ligature than the aortic coats recommended by Mr. Barwell. His choice finally fell upon nerve tissue, which was used as a ligature in tying the

right common carotid of a woman in whom hæmorrhage occurred into a malignant tumour involving a large region of the side of the face and head. The substance used was the fresh sciatic nerve of a calf; the ligature was cut off and left in the wound, which healed by first intention. On subsequent post-mortem examination the artery was found perfectly occluded, and its continuity unbroken, the result of ligation being most perfect, a depressed ring scarcely appreciable existing where constriction had been caused by the ligature.

Writing to Dr. Wyeth on these ligatures, Mr. Barwell remarks, "in the selection of a ligature the important points seem to me to be that the substance should be absolutely free from all taint of decomposition, and that it should be cleansed from any accidental impurity by a short immersion in some antiseptic fluid. If these essentials be secured, the choice of a particular substance is immaterial; sufficient strength, persistency to keep a safe knot, as also facility of acquisition, are the main considerations.

EXCISION OF THE TONGUE.

The method of removing the entire tongue through the mouth with scissors only, and without previously securing any vessel—a method adopted by Mr. Walter Whitehead, of Manchester—has been subject of comment during the year on more than one occasion. Mr. Whitehead's successful results were not repeated in all cases, and in two particularly, related by Mr. Fred. Treves and Dr. George Elder, hæmorrhage of so considerable a character was experienced that any possibility of leaving the arteries uncontrolled was out of the question. It is noticeable, also, that the blood came from the general floor surface of the mouth, and not from the linguæ; it was a copious oozing, and not a spurting; and in Mr. Treves' case the attempt to secure the linguæ by means of torsion signally failed, the brittle artery breaking off at the application of the forceps. Mr. Treves' final conclusion is to adopt, in any future case of the kind, Billroth's precaution of ligaturing both linguæ prior to excising the tongue.

LIGATURE OF THE INNOMINATE.

On the 9th of June Mr. Thompson ligatured the innominate artery of a patient in the Richmond Hospital, Dublin, on account of a subclavian aneurism. The patient was a man 45 years old, who first observed the disease ten months before entering hospital, and two months previously to the operation he had refused to have the attempt made. The aneurism, three and a-half inches in diameter, sprang from the second and third stages of the subclavian artery, and in performing the operation Mr. Thompson made use of the needle devised by Mr. Barwell for the innominate, the ligature employed being the same gentleman's broad aortic animal ligature. The case did well subsequently for some time, temperature and pulse maintaining a steady equable position and rate. Until the thirty-seventh day, however, repeated hæmorrhages occurred, and death took place on the forty-second day after the operation was performed. But one case of a similar kind ever survived so long, this having been operated on by Von Gräfe, and living for sixty-seven days after. In Mr. Thompson's patient it was found on post-mortem examination that the sinus from which the

bleeding came terminated in an ulcer, which involved the anterior wall of the junction of the innominate, carotid, and subclavian arteries. The innominate and carotid were filled with clots, and the subclavian was occluded by clots for half-an-inch of its extent. The ulcer was situated on the distal side of the ligature, the constricted part of the innominate not being involved. The hæmorrhages had apparently taken place from the innominate, as there was a recent blood stain on the cardiac side of the clot. None of the vessels were pervious to water forced in with a syringe. The aorta was atheromatous; consolidation was proceeding satisfactorily in the tumour. The whole case is a very interesting one.

PORRO'S OPERATION.

Dr. Clement Godson recently performed Porro's operation on a dwarf twenty-four years of age, and measuring four feet four inches in height. Her pelvis was very considerably distorted, and rendered resort to the operation a matter of urgent necessity for preservation of life. It was completed with perfect success, and a living child, twenty inches long and weighing eight pounds and a-half, was taken from the uterus. The time occupied by the operation was just one hour, and it was conducted from beginning to end without the occurrence of any embarrassments whatever. The mother and child both continued to do well subsequently, the temperature of the former not rising over 100° F., and the pulse-rate not exceeding eighty per minute. This singularly successful case will probably encourage the delivery of opinions on the advisability of more frequent adoption of such measures of relief in less urgent cases, and it is this tendency against which a stand may require to be made by less enthusiastic adherents of the doctrine of free surgery.

NEW ANTISEPTIC DRESSINGS.

The steady rate at which additions to the list of antiseptic dressings occur is a noteworthy indication of the activity displayed in perfecting surgical procedures to the utmost possible extent. The employment of carbolic acid has, in the past, been attended with so many serious drawbacks that it is easy to understand why this anxiety in searching for improved antiseptic substances should be exhibited. To the substitutes for carbolic acid already introduced in the form of boracic acid, thymol, and the like, we have now added iodoform and peat-mould. Iodoform appears to be well adapted for use in this direction, and a preparation of wool impregnated by an ethereal solution of the drug is highly eulogised as a dressing for wounds, and particularly those such as a hernia about the perinæum. Lint similarly prepared is also recommended, and by aid of the wool it is pointed out that perfectly aseptic conditions of perinæal wounds can be secured by enveloping the parts in a mass of the iodoform wool, with, as a further prevention, smearing the surrounding hairs with iodoform ointment. In many cases the use of iodoform dressings has been attended with most satisfactory results, and extended trial of them seems to be indicated as a desirable proceeding in surgery. Peat-mould is of very recent introduction into this country for surgical purposes, but as an antiseptic dressing it is asserted to possess well-recognised advantages,

while its applicability to cases of compound fractures, &c., pre-eminently adapts it for employment in such cases.

RENAL SURGERY.

Two important discussions have taken place during the year at the Clinical Society of London in connection with operations on the kidney, and the advantages possessed by Langenbuch's operation, whereby the kidney is reached for purposes of excision, &c., through a median opening in the front wall of the abdomen, were debated. Several operations for removal of renal calculi, and for relief of symptoms set up by presence of pus in the organ, have been recorded, the majority eventuating successfully. Nephro-lithotomy, as performed by Mr. Morris, has been repeated by Mr. Beck, who points out that favourable subjects for the operation should not be too fat, and that when pus in the urine affords indication that the stone in the kidney is setting up irritation, then the time for operative interference has arrived. Mr. Beck repeats what Mr. Morris pointed out in respect to the bleeding from the incised kidney. Though seemingly very profuse for a moment, it is at once and permanently controlled by the pressure of a sponge, and does not subsequently seem to cause embarrassment.

From the numerous cases reported before societies and in journals, in which grave operations on the kidney have been attended with success, it is evident that an increasing feeling of hope as to the consequences of such interference is growing up among surgeons, who will now proceed to cut into or remove a kidney with much less hesitation than would have been shown a few years ago. The most hopeless cases of this kind that are met with now are those extreme examples of degeneration in which the kidney is little more than a sac containing pus, and which yield the least likely of all probabilities of successful removal of the mass. A very considerable number of cases in which operative treatment for removal or evacuation of diseased kidneys has succeeded have been reported during the year, and it is a justifiable conclusion from consideration of these proceedings that a much more evident willingness to attempt to give relief to patients by such measures is exhibited now than formerly. In fact, this may be said of surgical operations generally; many which are now by no means uncommon would have been promptly rejected not very long ago, as involving an amount of risk not justified by the probabilities of success or even of relief to distressing symptoms.

GASTROSTOMY.

An increasing inclination to perform gastrostomy in cases where permanent relief of œsophageal stricture is found to be impossible is observable, and several cases in which encouraging results have been obtained are among the records of the year. From the nature of the diseases which necessitate the proceeding as a rule, and which are mainly of malignant character, the best prospect afforded by successful gastrostomy is only amelioration of the patient's condition. There seems good reason to think, however, that if it were not always, or nearly always, turned to as a last resource against death by starvation, if, that is, it were performed in earlier stages of disease,

at a time when the patient's powers were not at their lowest ebb, that better results might ensue from it, in so far that a longer existence might be anticipated, although, of course, no alteration in the ultimate course of the primary disease can be produced—only a deferring of the unavoidable termination.

RESECTION OF THE STOMACH.

The introduction into modern surgery, by Billroth, of resection of the stomach, has been followed by repetition of the operation on the part of other operators, with degrees of success varying from total failure to produce any favourable consequence, or even to avert death, to preservation of life for occasionally even considerable periods. This year the operation was performed in Italy for the first time—unsuccessfully—the patient suffering from cancer of the pylorus. In this instance the operation occupied two and a-half hours, and the stomach was united to the duodenum by fifty stitches. Death occurred from shock, and on post-mortem examination no secondary deposits were discovered in the body, so that, had recovery ensued, it is fair to assume that some years might have been added to the life of the sufferer.

EXCISION OF THE UTERUS.

The extraordinary advances in the region of abdominal surgery have in nothing been illustrated so much as in the success which has been obtained after operations for the removal of the whole uterus, on account of cancer, &c. This serious proceeding has been safely entered on by British surgeons on several occasions during the last year, the first operation of the kind in 1882 having been undertaken on January 3rd at St. Thomas's Hospital by Sir William MacCormac. The patient was admitted for obstinate constipation with signs of intestinal obstruction, and on examination cancer of the cervix was discovered, the rectum being pressed on by a large foreign growth. This was seen, when the abdominal cavity was opened, to be a tense and freely adherent cyst, beneath which the uterus and its appendages were hidden. On being punctured a large amount of foetid pus escaped, a portion of which found its way, in spite of all precautions, into the pelvic cavity. This cyst was removed with uterus and ovaries *en masse*, and no attempt to stitch up the edges of peritoneum was made, a large T-shaped drainage tube projecting into the vagina being left in the abdomen, and serving also for its irrigation. Subsequent formation of pus necessitated that the adherent edges of the wound should be broken down for its evacuation, but otherwise the case progressed most favourably.

A similarly successful case of extirpation of the uterus is recorded as having been performed at the close of last year in the Middlesex Hospital; and at a meeting of the Obstetrical Society in June a uterus was exhibited which had been torn away from a woman by an ignorant midwife, the patient eventually recovering. All these cases tend to prove that the female pelvic organs are tolerant of very full and considerable manipulation, and that the most apparently desperate measures may be resorted to where they are concerned with a prospective recovery being held in view.

BOOKS.

THE year just expiring has not been fruitful in the way of producing either a considerable number or a very valuable series of new works. Indeed, from a survey of publishers' announcements it is impossible to gather that even ordinary standards have been maintained, and were it not for one publication in particular, it would be difficult to redeem it from the charge of comparative barrenness. We have, however, one volume to show which fully deserves the opinion formed of it on all sides as being the most important medical work issued for a long period. We refer, of course, to "The Dictionary of Medicine," edited by Dr. Quain. This magnificent contribution to literature is an imposing volume of nineteen hundred odd pages, the intrinsic merit of which fairly maintains its pretentious appearance, and which is in all truth a dictionary of medicine in the best and fullest sense of the term. In completing the laborious duties of its preparation Dr. Quain has received assistance from over a hundred and fifty authorities, several of whom, alas! have not lived to witness the final acceptance of their work, but all of whom have faithfully performed the various tasks allotted to them. The only drawback in connection with the work is its unwieldy proportions, and it is possible to wish that the desirability of issuing it in two separate volumes had been entertained by the publishers. Nothing, however, can detract from its high importance and inestimable value as a library of reference, and it will long continue to be the standard work in this connection accessible to English students of medicine.

In this place we cannot undertake more than a brief mention of the principal books published during the year, and in most but the names can be afforded. We will therefore classify them, as far as possible, in the attempt to offer a rough survey of what has been accomplished, in a literary sense, during the preceding twelve months.

Medicine.—In addition to Quain's Dictionary, a new edition of Dr. G. W. Balfour's "Diseases of the Heart" has appeared, in which the author has brought the treatment of his subject down to date, and added important illustrative cases; "Medical Ophthalmology," a valuable and suggestive manual for students and practitioners by Dr. Gowers; "The Diseases of the Spinal Cord," a well-executed and profusely illustrated treatise on a subject hitherto all but neglected by writers and teachers, by Dr. Byrom Bramwell; "The Medical Adviser in Life Assurance," by Dr. Sieveking; a new edition of Dr. Bristowe's universally appreciated "Theory and Practice of Medicine," also of Dr. Playfair's "Midwifery," and of Dr. Graily Hewitt's well-known work on Uterine Diseases; "On Consumption in relation to its Contagiousness and Treatment," by Dr. Yeo, Dr. H. C. Clapp, and others; "The Diagnosis and Treatment of Diseases of the Chest," by the late Dr. William Stokes, Vol. I., published by the New Sydenham Society; "Electro-Diagnosis in Diseases of the Nervous System," by Dr. Hughes Bennett; "Medical Nursing," by Dr. Wallace Anderson; "Whooping Cough," being the Fothergillian Prize Essay for 1881, by T. M. Dolan, F.R.C.S.; "Chronic Bronchitis," by Dr. J. Milner Fothergill; "Morbid Urines," an excellent little manual for guiding clinical research, by Dr. C. E. Balle; a new edition of Meigs and Pepper's "Diseases of

Children;" Sir Joseph Fayrer's Croonian Lectures on "The Climate and Fevers of India;" "Health Resorts," a useful guide for doctors and patients, by Dr. J. Burney Yeo; a second edition of Dr. Edis's students' manual of the "Diseases of Women;" a new edition of Dr. Aitken's valuable handbook for students on the "Outlines of Science and Practice of Medicine," and which had long been out of print; and a series of "Clinical Lectures on Diseases of the Nervous System," by Dr. Buzzard, a work in praise of which no terms can be deemed too commendatory.

Surgery.—In the branch of surgery the most considerable addition to the list of works published during the year is the second volume of the "International Encyclopedia," chiefly by American authors, but which scarcely justifies the hopes formed of it; a new edition has appeared of Mr. Holmes' smaller work, and the following:—"The Surgery of the Rectum," being the Lettsomian Lectures for 1865, by Prof. Henry Smith; on "In-Knee Deviation," by Dr. Little and Mr. E. M. Little, a very useful and reliable work; new editions of Mr. Nettleship's "Diseases of the Eye;" of Mr. Field's "Aural Surgery;" of Dr. Liveing's "Handbook on Skin Diseases;" "Clinical Surgery," by Billroth, one of the Sydenham yearly volumes; "Diseases and Injuries of the Eye," by J. R. Wolfe, M.D.; "The Surgery of Deformities," by Mr. Noble Smith; a translation of Politzer's important work on Diseases of the Ear, by Dr. J. Patterson Cassells; a third edition of Dühring's treatise on Skin Diseases; "The Surgical Treatment of Hæmorrhoids," by Mr. Walter Whitehead, of Manchester; a new edition of the late Prof. Spence's excellent "Lectures on Surgery;" the first part of a new work of a very original and serviceable character by Mr. Southam entitled "Regional Surgery," and dealing with the head and neck; "On Cancer of the Breast," by Mr. T. W. Nunn, an important contribution to the study of cancer; "Carcinoma and Sarcoma," by Mr. H. T. Butlin, F.R.C.S.; "Scrofula and Gland Diseases," by Mr. F. Treves; "On Concussion of the Spine," a new edition of Mr. Erichsen's well-known work, and an original treatise on Diseases of the Spine and Concussion by Mr. Page, of St. Mary's Hospital; "On Ovarian Tumours, their Pathology and Treatment," by Mr. Spencer Wells.

Anatomy and Physiology.—In these departments of science the principal events of literary interest have been the publication of a new and improved edition of "Quain's Anatomy;" the additions to which bring it fairly abreast of recent discoveries; and the appearance of the first volume of Mr. Reeve's long-promised work on "Human Morphology," a very disappointing production. "The Tissues and their Structure" is a useful little handbook for students of histology, by Mr. A. S. Kenny, of King's College. "Practical Exercises in Physiology," by Dr. J. Burdon Sanderson, will be found essential to candidates for higher scientific examinations; a new and enlarged edition of Harris and Power's "Manual for the Physiological Laboratory;" "The Physiology and Pathology of the Blood," by Dr. Norris, in which the author's important researches are fully detailed, and their bearings explained; and finally, a crushing exposure of the shams perpetrated by antivivisectionists, by Prof. Owen, and entitled "Experimental Physiology, its Benefits to Mankind."

Materia Medica, Therapeutics, and Chemistry.—Dr. Sidney Ringer's "Handbook of Therapeutics" has run through another edition within the past few months, and is again out of print; "Dental Materia Medica and Therapeutics, with Pharmacopœia," by Drs. Gaddes and Stocken, third edition; "General Medical Chemistry," by Dr. Witthaus; "Nitro-Glycerine in Angina Pectoris," by Dr. Murrell; "London Hospital Pharmacopœia;" and a new edition of Dr. Thorowgood's invaluable "Students' Guide to Materia Medica and Therapeutics."

Annual Volumes and General Works of Reference.—The third volume of the exhaustive Catalogue of the Surgeon-General's Library at Washington has just been issued, bringing the work to the end of D; next to it in point of size among this year's publications comes Dr. Tidy's "Legal Medicine," Vol. I. The various societies present the usual volumes of reports, all more or less maintaining their standard of excellence; and several hospitals have issued "Reports" dealing with the work done in the reception wards during the preceding year. In this place also may be mentioned a useful and concise little volume on "The Laws relating to Medical Men," by Mr. Greenwood, a Barrister of the Inner Temple; and catalogues of the pathological preparations in the Museums of the Royal College of Surgeons, and St. George's and University College Hospitals; and finally, a work invaluable to every student of medical questions, "The Medical Digest," by Dr. Neale, a new and improved issue of which had appeared during the year.

THE YEAR'S LOSSES.

FIRST, because most prominent among the deaths which have thinned the ranks of medical men during the past twelve months, both on account of his premier position and of his having so recently been present in our midst, the loss sustained in the death of SIR THOMAS WATSON springs to mind. Born in 1792, this venerable physician lived to enjoy every dignity and advantage that could fall to the lot of a universally loved and respected practitioner and teacher; throughout an unusually long and productive life he ever maintained a demeanour that secured for him the respect and affection of colleagues and juniors; and as the brightest ornament of which the medical profession has boasted in the present century, his memory will long remain to influence for good all those who are rightly emulous of imitating to their own ability the example set by his protracted but unspotted career. As a lecturer at King's College the late Sir Thomas Watson (then Mr. Watson) delivered those clinical discourses on the "Practice of Physic" to which students and practitioners alike both ever turn with renewed pleasure and profit, and which will remain an undying memorial to the learning and skill of their author. The College of Physicians retained the deceased baronet's services for seven years as President, and he also acted as its first representative on the General Medical Council. He was created a baronet in 1866, and died Monday, December 11th, surrounded by friends and respected by every one to whom his name was at all familiar.

JOHN SOUTH.—John South, who died at his residence Blackheath Park in January, at the ripe old age of 85,

was an eminent Fellow of the Royal College of Surgeons, which conferred its Presidency on him in 1851; and he was again elected to the same office in 1860. He had previously held the posts of Hunterian orator, "Arria, and Gale" Professor, Member of the Council and of the Court of Examiners, having been regarded in his latter capacity as a very stiff examiner. Mr. South was educated at Guy's Hospital, and subsequently became attached to the surgical staff of St. Thomas's. He translated Chelius' "System of Surgery."

DR. MOFFITT.—Surgeon-Major Moffitt, of the Army Medical Department, entered the service in 1858, and in connection with the operations conducted by Major (now Colonel) Gordon's army in China, he achieved an amount of successful labour that earned for him a very flattering recognition at home. Dr. Moffitt held numerous appointments, and passed through a series of offices in his military career, in all of them gaining the goodwill of superiors and love and esteem from those over whom he was placed. He died at Southampton on February 8th.

DR. WILLIAM PRATT.—Dr. William Pratt, F.R.C.S., who died at his residence at Newtown, Montgomeryshire, held a high position among the local practitioners of medicine in his neighbourhood, and had proved his claim to be considered a promising and useful member of the profession. He died of pneumonia, which set in after he had been for a long period in unremitting attendance upon a patient suffering from that disease in an imperfectly drained portion of the town. Dr. Pratt was a Graduate in Arts of Aberdeen University, and of Medicine at Liège University, holding also the F.R.C.S. Eng. and L.R.C.P. Lond. He was actively interested in the medical charities of Newport, where his loss is very keenly felt.

DR. T. BEVILL PEACOCK.—By the death of Thomas Bevill Peacock, St. Thomas's Hospital was deprived of its consulting physician, and the profession in London of one of its best known and most respected members. The circumstances of Dr. Peacock's last illness were peculiarly sad. He was present at St. Thomas's with some friends on May 30, when he was seized with an attack of paralysis, and, being at once carried to a bed in the adjoining ward, he was carefully and affectionately attended by his junior colleagues; but in vain, for he died the same evening on the very spot where he had formerly frequently ministered to the sick himself. The deceased physician was born at York, in 1812, and, after spending some time as a medical pupil, he entered at University College, and St. George's Hospital in 1833. In 1835 he became M.R.C.S. and L.S.A., and then spent some time in travelling abroad. He graduated at Edinburgh University in 1842, and L.R.C.P. Lond. in 1844, and soon after he laid the foundation of the Victoria Park Hospital by starting a dispensary for chest diseases in Liverpool Street. In 1849 he was elected assistant physician to St. Thomas's to which charity at his death he was consultant. Dr. Peacock was author of several important works, a conscientious and successful teacher, and a sound practitioner, while he was socially a general favourite with all who could claim his friendship.

THOMAS O. DUKE, M.R.C.S.—Mr. Duke was a surgeon of the old school, who had been in practice for forty-

two years in Kennington and Clapham. He was born in 1818, and educated at Guy's Hospital, and after obtaining the M.R.C.S. and L.S.A. diplomas, entered on general practice, in which he was very successful.

DR. CHARLES MOREHEAD, C.E.I.—Charles Morehead, M.D., C.E.I., was a distinguished Principal of the Grant Medical College at Bombay, and Physician to the Jarnsetjee Jejeebhoy Hospital, having entered the Bombay Medical Service after a successful career at Edinburgh University. He died at Redcar, Yorkshire, on August 24, aged 75.

SIR JAMES ALDERSON.—The obituary list that includes the two names of Watson and Alderson may well be considered to be a heavy indication of loss; both of these veteran physicians have passed away during the past year, Sir James Alderson preceding Sir Thomas Watson by a few weeks only, but dying at the age of 87. He succeeded the latter as President of the Royal College of Physicians on his retirement, and held office three years. As an undergraduate at Cambridge, the deceased took a good position, and on taking his degree was placed among the Wranglers, being rewarded with a Fellowship at Pembroke. He obtained the M.D. of Oxford in 1829, and next year the Fellowship of the College of Physicians. Originally in large practice in Hull, he came to London eventually and settled there, and on the foundation of St. Mary's Hospital in 1851 he was elected senior physician on its staff, which position he resigned in 1867. Sir James Alderson was a D.C.L. and F.R.S.

J. T. CLOVER, F.R.C.S.—Mr. Clover's name will always be intimately associated with the history of anæsthetics, in connection with the administration of which he was the inventor of important and ingenious appliances. He was educated at the Norfolk and Norwich and University College Hospitals, and at the last-named institution held the posts of house-surgeon and chloroformist, and later on that of lecturer on anæsthetics. Entering on professional practice in London, he soon obtained a greater success than his health, never very strong, enabled him to cope with, and for many years the duties of his life told heavily upon his limited strength. Never for a moment flinching, however, from full performance of the work that fell to his lot, he was also constantly endeavouring to perfect the means of facilitating the use of anæsthetic agents without risk to the life of patients; in the department of surgery also, his inventive powers were brought to bear, and among the many ingenious contrivances devised by him is the well-known exhausting bottle and catheter for removing debris of calculi from the bladder after lithotomy. Clover was born in 1825, and in the record of his well-spent and highly useful life may be read a lesson of devotion and assiduity to the business of existence that will always carry with it an influence for continual good.

DR. R. W. LYELL.—Robert Wishart Lyell, born in 1849, and educated at King's College, where he gained a Warneford scholarship, graduated in Medicine at the London University, and subsequently became surgical registrar, medical tutor, and assistant surgeon at the Middlesex Hospital. The deceased had been appointed to deliver the introductory lecture at the opening of the

present session at the school to which he was attached, and it is a melancholy coincidence that he died on the very day to which his friends and well-wishers had looked forward as the one on which the address would have been given from his lips. Among those who knew him well but one feeling, a feeling of painful regret, is experienced at the loss sustained by his death; for though not generally known beyond the sphere of his active exertions, and in spite of his having contributed but lightly to our literature, yet Lyell gave such promise of future performances, and was so enthusiastically devoted to the interests of his profession, that his death can only be regarded as a deprivation of the most serious description. Warm-hearted, generous, and most kindly-disposed, he will long be gratefully and mournfully remembered.

GEORGE CRITCHETT, F.R.C.S.—The most brilliantly successful operating ophthalmic surgeon of his time, George Critchett died on November 1st, after a short illness, leaving behind him a renown which will long preserve his name in the annals of eye-surgery. After obtaining the Membership of the Royal College of Surgeons he became assistant-surgeon and lecturer on surgery

at the London Hospital, and following the special practice of an ophthalmic surgeon, soon afterwards came on the staff of the Moorfields Eye Hospital. At the recent Congress in London he was Vice-President of the Ophthalmic Section, and had been President of several prominent medical societies. In 1870 he joined the Council of the Royal College of Surgeons, and his widespread fame as an oculist obtained for him the distinction of honorary membership of numerous foreign learned associations. Mr. Critchett was acknowledged to be a pre-eminently skilful operator; but his contributions to surgical literature have been fairly numerous, and of great intrinsic merit. He leaves no enemies, and all his friends are truly mourners for his loss.

Death has been likewise busy in the profession abroad, with the result that many names familiar as those of leading members of our body are to be remembered only among the shadows of the past. In America the DRAPERS, father and son, have gone to their rest, the elder earlier in the year, the younger but a few weeks since; and WOOD, whose fame as a surgeon had spread to this country and to Europe.

Ireland.

MEDICO-EDUCATIONAL PROGRESS.

THE year 1882, looked back upon from a medico-educational standpoint, has been one of unusual activity and of progress towards much-needed reform, in which the College of Surgeons has taken the lead. The effort which the Council of that College had been engaged upon for the last two years—to establish an entirely new system of education and examination—was brought to a conclusion in the early part of the year. The scheme approved by the College, it will be recollected, had for its object the subdivision of the four years of study into four periods—*a.* Preparatory; *b.* Preliminary; *c.* Theoretical; and *d.* Practical; each period having its fixed quota of suitable study, and, at its conclusion, an examination before the succeeding period was taken up. The scheme decreed the abolition of certain lectures, and thus evoked the violent hostility of teachers whose fees were thereby reduced in amount, and that hostility had the effect of delaying the promulgation and enforcement of the new system until the month of July last. It then, having been confirmed by the Home Secretary on the behalf of the Queen, was declared to be the law of the Irish College of Surgeons, and was made compulsory on students commencing study after that date. Thus was completed the most thorough and most important reform of medical education in Ireland which has taken place for the past quarter of a century, and we anticipate from it the most valuable results to Surgery in Ireland. But the new system would have been imperfect if no steps had been taken to make honest and real the studies therein set down, and for this object a further scheme of teaching reform was adopted by the Council of the College, and is now meeting with the same resistance by interested parties as was encountered by the new system of education and examination.

It had come to be notorious that certificates of "diligent" attendance on lectures and hospital were sold without reserve by certain schools and hospitals to students who not only did not make a pretence of attending the courses of study, but who were so situated that it was physically impossible that they could even go through the form of attendance. Students engaged from morning to night in shops and offices were known to present themselves on many occasions with a full supply of such certificates, and, by this system of fraud, obtained admission to the profession, and therefore the Council of the Irish College of Surgeons, being decided that their new system should not be nullified by a continuance of these practices, adopted a series of rules by which the actual number of attendances should be guaranteed, not only by the lecturer, but by the registrar of the school and by the student himself; so that in future, if a false certificate is issued, there must be three parties to the falsity, and the student who avails himself of such means to gain entrance to the profession will be liable at any time to forfeit his diploma if it is ascertained that false statements have been made in his certificates.

Notwithstanding these public acts of the College—duly notified to all schools and hospitals within its jurisdiction—it became known, shortly after the opening of the present winter session, that the Ledwich School was hard at work at the business of lecturing for three hours in the evening those students who wanted certificates, but who could not leave their shops and offices to obtain them legitimately. As it was obvious that certificates issued under these circumstances could not possibly be truthful and genuine, and must necessarily be—at best—an evasion of the regulations respecting attendance, the Council of the College found itself compelled to grapple with the attempt to impose such

certificates upon them, and, being unable to distinguish between the real and the sham certificates, it was obliged to disfranchise peremptorily any and every school which engaged in this trade. The resolution of disfranchisement was subsequently re-affirmed, but as it was represented to the Council by the night-students that the opinions and orders of the College had been concealed from them, and that they had been thereby induced to enter for night lectures, the Council consented not to enforce the disfranchisement of the School until after the termination of the present winter session.

Thus it appears that the Irish College of Surgeons has been engaged for the year past in a war against old abuses and corrupt practices in connection with the Irish medical education, and is, at present, in possession of the field. It is to be hoped that the Council will have the courage to carry into effect the policy which it knows to be right and honest. It cannot reasonably expect to reform out of existence, in a few months, lucrative abuses which have taken root through many years of uninterrupted growth, but the College has the power to do so if it persists, and if it fails to do so, it will have to accept the responsibility of connivance at practices which are a disgrace to any profession.

The University of Dublin has not made any changes of system within the year which are specially worthy of note.

ROYAL IRISH UNIVERSITY.

This University commenced operations in the early part of the year. Its first official act, after the regulations had been framed by the Senate and confirmed by the Lord Lieutenant, was the appointment of Fellows and Examiners, and the course adopted by the University was such as to communicate a shock to those who wished the institution a prosperous career, and to disgust those who looked forward to a wide and useful sphere of action for the University. The Senate resolved to allocate 24 of the Fellowships, as follows:—Classics 6; English 4; Mental and Moral Philosophy 4; Mathematics 4; Natural Philosophy 4; Chemistry 2; altogether omitting from consideration the medical profession. At the same time they appointed 17 examiners for medical degrees, and, in doing so, made it at once manifest that, according to the feeling of the Senate, medical and scientific attainments—intellect and industry—are of no value when placed in competition with politics and religion and the influence of the family party. In the selections made all merit outside the Queen's and Catholic Universities was almost absolutely ignored, while a crowd of examiners—many of them palpable mediocrities—were chosen as examiners.

The policy thus evolved was openly defended on the novel ground that the Royal Irish University was made for the advantage of the Professors in the Queen's and Catholic Universities, and that no one else had a right to expect advancement, a principle which, however true it is, is certainly not compatible with educational prestige.

In the course of the year the University held matriculation and medical examinations, but as the former are scarcely sufficiently tried to judge of the estimation in which the University is likely to be held, and the latter were necessarily restricted to those students who had pursued their studies in the Queen's Colleges, we cannot venture to predict the future success or failure of the new University therefrom.

In our next Retrospect of its proceedings we shall be in a better position to point out the niche which the Royal Irish University is destined to occupy in Irish education. It may, however, be safely asserted that its status will depend on its recognition of merit and its independence of extraneous influences, and that if it takes the rôle of a nursery for a favoured few religionists or politicians, it will prove a greater failure than the University which it has superseded.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

The King and Queen's College of Physicians, which appears to unite the vigour of youth to the dignity of age, has, during the past year, pursued the even tenour of its way without any special incident. Dr. George Johnston, who had held the presidential chair for two years, vacated it last October in favour of Dr. William Moore, who was unanimously chosen to succeed him. Two vacancies in the King's Professorships occurred—the first by the resignation of Dr. Aquila Smith, and the second by the lamented death of Sir Edward Sinclair. To the former Dr. Walter G. Smith, author of the well-known Commentary on the British Pharmacopœia, was appointed; and to the latter Dr. J. Rutherford Kirkpatrick—appointments which were both very favourably received. A large number of licentiates were admitted to the newly-created grade of membership, and a great and increasing number of students passed the examination for the license of the College. Among these latter were numerous ladies, one of whom made an unusually brilliant examination. The efforts of the fair sex to enter the portals of medicine were not always successful—the Court of Examiners being not invariably sufficiently gallant to admit all lady candidates. This is as it should be, and the experiment of medical women is thus being fairly tried by this College. When they are fit to pass they do pass; and after that the practical test of public experience will show the ladies themselves whether it will be wise for them to persevere, or, in fact, whether it will “pay” to do so. The College has resolved to grant a diploma in sanitary science, and has appointed a special Court of Examiners, including two non-medical professional men, a barrister, and an engineer. This step has also met general approval. The Colleges of Physicians and Surgeons of London are now actually conferring upon the question of giving a conjoint diploma; and we trust that the sister colleges here will see their way to follow this example. The question of night lectures, which has proved such a burning one in Stephen's Green, has not yet been approached by the King and Queen's College of Physicians.

IRISH POOR-LAW SUPERANNUATION.

The central position in Poor-law medical affairs, which occupy in Ireland a most important part of the attention of the profession, has been occupied during the past year by the prospect of legislation on superannuation of union officers. That subject has for years past been ripening into a burning question, and, after constant agitation on the subject, the Irish Medical Association had ventured last last year on the introduction of a Bill of which Mr. Meldon kindly took charge. That Bill contained clauses which provided that, when a Poor-law medical officer became incapable of discharging his duty, he might apply

to the Local Government Board, who—after satisfying himself that he was really incapable—would be bound to award him such pension as they thought fair and such pension should thenceforward be payable compulsorily by the guardians of the district. That proposition did not find favour with the Local Government Board, because it left the amount of pension to their discretion, and was calculated, therefore, to embroil them with boards of guardians. Accordingly, the Bill was allowed to drop, and the Local Government Board—of their own motion—issued a circular, similar to that which had been issued in England, by which they informed the guardians, that—in future—they would sanction no pension greater in amount than that which might be granted if the Civil Service Scale were in force in the Poor-law service.

Although this decision was of questionable legality, the Poor-law medical officers did not dispute it, because they felt that the Civil Service Scale was not unreasonable under the circumstances; but the Irish Medical Association, seeing that the circular of the Local Government Board and the precedent established in England gave Poor-law officers a claim upon Parliament, decided to introduce a remodelled Bill on the subject in the session 1881-82. In this intention they were joined by the non-medical union officers, who established a very active and efficient organisation of their own. After some difficulty in the preliminary *pourparlers*, both associations were brought into cordial co-operation for the promotion of the Bill, and by them every possible pressure was brought to bear upon the Government, the Local Government Board, the Members of the House, and the Boards of Guardians. Deputations were received by Mr. Forster and Mr. Herbert Gladstone, and it was then announced that the Government would themselves take the question in hand, and introduce a Bill, the salient points of which would be—

- a. The adoption of the Civil Service Scale.
- b. The making of the grant of pensions compulsory; and
- c. The striking of a general pension rate throughout Ireland, to which each union would contribute a small fraction of 1d. in the pound, and out of which all superannuation allowances would be paid.

This Bill was introduced early in the session by Mr. Herbert Gladstone, but, at once, the clause which transferred the granting power to the Local Government Board was received with violent hostility, especially by the Irish irreconcilable section of the House, who opposed it with especial *gusto* because the proposition was brought forward by the Premier's son. To meet this opposition Mr. Herbert Gladstone at once gave a promise that—in committee on the Bill—he would restore the granting power to the guardians. This concession would have rendered the measure almost completely useless to the officers interested, inasmuch as the sole purpose of the Bill was to take from the guardians a discretion which they had, for years past, abused; and the two Associations were, therefore, obliged to notify Mr. H. Gladstone that they should withdraw their support and hold themselves at liberty to move amendments in the Bill at a subsequent stage. After a very long delay, during which all domestic legislation was brought to a standstill by the obstruction of the Irish members, the Bill got to a second reading within the last few days of the session, and, as the hostility to it still

continued, Mr. H. Gladstone was obliged to send it to a Select Committee. That Committee met in the first week in August, and before it the Irish Medical Association was represented by Dr. Jacob, and the Union Officers' Association by Messrs. Cope and Atkinson. Mr. Robinson, Vice-President of the Local Government Board, was examined on behalf of this department; Dr. Moore, of Ardee, as an independent medical witness, and two or three Cavan and Belfast guardians, as opponents of the measure. At first, the Local Government Board declined absolutely to make the grant of pension compulsory on the guardians, but, after a time, they yielded the point, and it was agreed that the two Associations should renew their support of the Bill on condition that their amendments in it were adopted, and that the Local Government Board should have a special power to reduce pensions in exceptional cases.

In consequence of the continued hostility of the Irish members of the Select Committee, it became evident that the Bill could not be fully discussed before Parliament was prorogued. It was, therefore, determined to report the Bill to the House with the amendments agreed to by the two Associations, and to re-introduce it in that form in the next Session of Parliament.

We, therefore, entertain a sanguine hope that the measure will become law before next July, in such a form as to confer great and lasting benefits upon the Poor-law medical officers of Ireland.

OTHER POOR-LAW LEGISLATION.

It will be understood that, the superannuation question being predominant, other questions affecting the Irish Poor-law services have been obliged to stand, especially as it is not wise to promote more than one Bill in Parliament at the same time. The subject of the abuses of medical relief (in which the Irish Medical Association had already proposed a Bill) remained in abeyance, as well as the scheme for establishing a Widows and Orphans' Fund for the Irish Poor-law Service.

VACCINATION REFORM.

The death of Sir Edward Sinclair, Director of the Vaccine Department of the Local Government Board, afforded to the Association an opportunity of pressing for a reconstruction and enlargement of that department, with a view to greater efficiency in the administration of vaccination law. Accordingly, a memorial was presented to Government, in which it was pointed out that nothing like an efficient system of enforcing vaccination existed in Ireland—that there was no means, such as exist in England, of ascertaining whether the operation is properly performed, or produces the desired protective result—that in point of fact, vaccination defaulters were not always reported to the guardians, and, if reported, are seldom prosecuted; and that, in consequence, a substantial proportion of the population of Ireland were either not at all, or else insufficiently vaccinated, to the great danger of the community. These representations by the Irish Medical Association met with the anticipated disregard by the Local Government Board, to whom they were sent by the Government. It would not suit that Board to trouble itself about vaccination, any more than it suited it to undertake any responsibility for sanitation, and it therefore

shelved the memorial, and perpetuated the office for collecting lymph which is dignified with the title of the Vaccine Department of the Local Government Board.

TENURE OF OFFICE OF POOR-LAW MEDICAL OFFICERS.

The circumstances under which Dr. Kenny was dismissed by the Irish Local Government Board from his office of Medical Officer of the North Dublin Union engaged special attention this time last year. The Board, it will be recollected, had availed itself of the power given by the Poor Relief Act to "deem unfit" a union officer, and so dismissed Dr. Kenny. In January, 1882, that gentlemen proceeded by *mandamus* to compel his reinstatement; but the arguments in the case had not concluded when the Board agreed to sanction his return to office, so that their power to dismiss an officer for an offence unconnected with his capacity to do his duty was not brought to a judicial decision. In the autumn a case in the same section of the Act arose upon the removal from office of Dr. O'Reilly, Medical Officer of Lismore Workhouse. The facts, already well known to our readers, were as follows:—An altercation took place, in which the doctor, the master, and fever nurse were engaged. A sworn investigation was held, and the guardians resolved to reprimand the master and nurse, and get rid of the doctor. This decision was so manifestly unjust that, when the minutes came before the Local Government Board, they wrote to the guardians stating their opinion that the doctor had not deserved exceptional treatment. Notwithstanding this, the guardians adhered to their determination, and the Local Government Board was placed in the dilemma of dismissing, at the bidding of the guardians, an officer whom they had themselves, in a certain sense, acquitted.

To escape this difficulty they wrote to the doctor, saying that the guardians were entitled to suspend him, and at the same time sent a copy of their letter to the guardians, who straightway acted on the hint by proposing to suspend him. To avoid this, Dr. O'Reilly, against the advice of the Irish Medical Association, resigned his office, thereby depriving them of the opportunity of raising the legal question whether an officer against whom no charge of incapacity has been made can be "deemed unfit" and thus removed from office.

The entire transaction was one extremely serious for the interest of Poor-law medical officers, because it not only created a precedent for future removals of such officers, but it was a complete abandonment by the Local Government Board of its protective function. In this view the Irish Medical Association would certainly have contested the matter at law if Dr. O'Reilly had not resigned; but being prevented from doing so they entered the strongest protest against the course adopted by the Local Government Board, and reserved further action until the next case arises, which will enable them to test the permanency of tenure of Poor-law medical officers by a judicial decision on the subject.

THE IRISH ACADEMY OF MEDICINE.

The facilities for inter-communication of professional experiences between physicians, surgeons, pathologists, and obstetricians in Ireland have been greatly improved by the establishment in the autumn of the past year of the Irish Academy of Medicine. Originating many years ago

in the mind of Dr. Lyons, M.P., the project has recently received special consideration because of the difficulty experienced in maintaining the separate existence of the various societies which have hitherto been the medium of professional intercourse in Ireland. The Surgical Society alone may be said to have flourished, while some of the other societies can scarcely be said to have lived. This condition of affairs arose, as we think, from two circumstances. In the first place the expenses of the Surgical Society were paid by the College of Surgeons, and, therefore, as people are well disposed to accept privileges for which they pay nothing, the attendance at its meetings was generally sufficient. But this does not altogether explain the circumstances, because the Medical Society received a considerable and well-deserved support from the College of Physicians, yet it barely languished. One of the chief causes, as we are vain enough to think, of the decadence of the societies was to be found in the fact that their proceedings were not published in any true sense of the word. Physicians and surgeons will not throw away their time, labour, and brains upon a communication which is destined for burial in a volume of Transactions six months subsequently, and which obtains a very limited ephemeral publicity, meanwhile, in the pages of a periodical of local and limited circulation; and as all the societies, save the Surgical, doomed their contributors to suffer extinction in this way, it was not wonderful that papers were scarce and subscriptions equally rare. After the termination of the 1881-2 session the project for amalgamating these societies into one Academy began to be agitated, and it was received with general approval. The members of the societies consented almost without exception, but the councils of the societies in some cases resisted their absorption into the general body of the Academy. Time was lost awaiting the decision of the Council of the College of Surgeons as to the proposed extinction of the Surgical Society, but the necessary consent having been obtained, a series of preliminary meetings of the promoters of the Academy were held, at which rules were discussed and finally adopted. In brief, these rules were as follows:—*a.* All Members of existing Societies, and Fellows of either of the Irish Colleges, to be Members of the Academy *ipso facto* on paying the subscription. *b.* All others to be balloted for by the General Council, one black bean in four to reject. *c.* Each of the four Societies to be resolved into a Section of the Academy, and to transact business in the usual manner once monthly as such Section. *d.* Each Section to be ruled by a Council elected by the Academy. *e.* Each Sectional Council to send two delegates with its Secretary and President, to form the General Council of the Academy. *f.* None but Fellows to have any voting powers. *g.* All transactions of Sections to be published in a yearly volume, weekly abstracts being printed for the use of such weekly journals as apply for them. These are the abstracts which we shall present to our readers in future.

The preliminary arrangements having been completed, a general meeting was appointed for constitution of the Academy and election of officers. Up to this time the Council of the Obstetrical Society had declined co-operation, although the members

of the Society had almost unanimously approved of the merging of the Society in the Academy; but when it became evident that the Academy would establish an Obstetrical Section of its own, the Council of the Society held a special meeting and resolved to join in the scheme. On the 22nd of November the elections were held and the Academy was born; the councils for surgical, pathological, and medical lectures were chosen without much contest, but in the case of the obstetric council, three gentlemen known to have been hostile to the Academy were rejected, and their rejection gave occasion for a virulent attack on the Academy by the *Freeman's Journal*, which sought to prove that the ostracism of these members was the result of politico-religious animosity. Notwithstanding this effort the Academy has already held several meetings with much success, and it promises to be a valuable means for the advancement of medical and surgical science in the future. If it is to fulfil its purpose, it must be administered in the widest and most liberal spirit. Anything like cliquism in favour of any politics, religion, person, party, or journal would certainly be the death of the organisation, and we trust that the councils, both general and sectional, of the Academy, will exercise the utmost firmness in excluding all bias of this sort. We shall certainly do our best to keep the institution free of all such disturbing and dangerous influences.

Dr. Banks, Physician to the Queen, has been elected the first President of the Academy; Dr. William Moore (President of the College of Physicians), Dr. Barton (President of the College of Surgeons), Dr. Purser, and Dr. Denham have been chosen Presidents of the Medical, Surgical, Pathological and Obstetric Sections respectively. Mr. Thomson is the honorary general secretary, and Dr. Robert McDonnell, honorary general treasurer. Two subsections were also formed—one on Hygiene, under the presidency of Dr. Cameron, and the other on Anatomy, under that of Dr. MacAlister.

We heartily wish the Academy every success.

APPOINTMENTS.

Several changes of importance in the Professoriate of the Irish Medical Schools and in the Staffs of the Clinical Hospitals have taken place within the past year. In the School of Physic attached to the University of Dublin, the death of Sir Edward Sinclair, and the resignation of Dr. William Moore, who was elected President of the College of Physicians, caused vacancies in the King's Professorships of Midwifery and of Practice of Medicine, to which Dr. Finny, of the City of Dublin Hospital, and Dr. Rutherford Kirkpatrick were appointed. Upon these appointments, which are made by the Fellows of the College of Physicians, subject to the approval of the Board of Trinity College, a much-disputed question arose as to whether candidates should be restricted to those who were willing to resign their hospitals and join the clinical staff of Sir Patrick Dun's. The matter is referred to by us in another part of this issue.

In the School of the College of Surgeons vacancies occurred in the Professorships of Practical Anatomy and of Ophthalmology, by the death of Dr. Philip Bevan and the resignation of Dr. Swanzy. The opportunity was availed of by the Council of the College to alter the arrangements

of the Anatomical School, and to appoint a Professor who could give the whole of his time to his professorial duties. To the office thus created they subsequently elected Dr. D. J. Cunningham, Assistant under Professor Turner in the Edinburgh University Dissecting Rooms, and the selection has been fully justified by the character which the new Professor has, since his appointment, added to School. Dr. Jacob succeeded Dr. Swanzy in the Professorship of Ophthalmology.

The Carmichael College sustained within the year a very severe loss in the untimely and much-regretted death of Dr. Reuben Harvey, its distinguished lecturer on physiology, who died of typhus after a prolonged illness. The feeling of sorrow felt by the profession was marked by the fact that a Harvey memorial fund was at once set on foot, to which a sum was subscribed sufficient to provide valuable prizes for meritorious physiological essays. Dr. Harvey's place in the Carmichael College has since been filled by Dr. Stewart Woodhouse.

In the Ledwich School no change of much importance took place in the teaching staff within the year.

In the Catholic University School the death of Dr. Hayden left a blank in the office of Lecturer on Anatomy and Physiology, which has since been filled by Dr. Christopher Nixon.

In the Meath Hospital no change took place.

In the City of Dublin Hospital, Dr. Finny's resignation, in order to join Sir Patrick Dun's Hospital, in connection with the King's Professorship of Medicine, to which he was appointed, led to the election to the hospital staff of Dr. G. F. Duffey, Physician to Mercer's Hospital. Dr. A. V. Macan was also obliged to resign his position as Gynaecologist to the Hospital to take up the more extended duties of Master of the Rotundo, and to the office thus vacated no appointment has yet been made.

In the Richmond, Whitworth, and Hardwicke Hospitals no change of staff has taken place save the appointment of Dr. Jacob as Ophthalmic and Aural Surgeon, *vice* Dr. Fitzgerald, resigned. Dr. Lentaigue, Assistant Surgeon, having joined Jervis Street Hospital, Dr. A. Newton Dickenson was appointed Assistant Surgeon in his stead.

In Stevens's Hospital no important change took place.

In Mercer's Hospital Dr. Charles Knight was elected to succeed Dr. Duffey, who, as above stated, was appointed to the City of Dublin Hospital. Dr. Ward was also appointed Surgeon to the Hospital, *vice* Dr. Mason, resigned.

In the Surgeoncy of Jervis Street Hospital, the death of Dr. Forrest created a vacancy, to which Dr. Lentaigue, Assistant Surgeon to the Richmond Hospital, was appointed.

In the Mater Misericordiae Hospital, Dr. Michael Boyd, of Kingstown, succeeded, as Physician to the Hospital, Dr. John Hughes, deceased.

To St. Vincent's Hospital, Dr. Cox, of Sligo, was appointed, and subsequently Dr. McArdle was chosen to succeed Dr. Keogh, resigned.

The Mastership of the Rotundo Lying-in Hospital, which was occupied for the past seven years by Dr. Atthill, to the great advantage of the institution, became vacant by the lapse of the period of office, and to it Dr.

Macan, Gynaecologist to the City of Dublin Hospital, was elected without a contest, the choice of the Governors being generally much approved.

OBITUARY.

OUR record of deaths amongst the profession in Ireland includes many well-known names. Senior amongst the deceased were Dr. C. H. Purdon, of Belfast, and Dr. Hans Irvine—for many years a Councillor of the Irish College of Surgeons, and an intimate friend of the chiefs of the past generation; Dr. John Hughes, Physician to the Mater Misericordiae Hospital and to the Dundrum Central Criminal Asylum. Dr. J. K. Forrest, Surgeon to Jervis Street Hospital, and Dr. Thompson, of the Lisburn Infirmary, come next in seniority—the latter gentleman, who may be said to have been the first provincial surgeon in Ireland, having been killed by a locomotive at Dunmurry Station.

Dr. Leith Adams, of the Cork College, and Dr. Reuben Harvey, of the Carmichael College, were also both men of note in their own specialities. Dr. Philip Bevan was long known and esteemed as a skilful anatomist. Sir Edward Sinclair held a high position as King's Professor of Midwifery in the School of Physic, Director of the Vaccine Department of the Local Government Board, and Midwifery Physician to Sir Patrick Dun's Hospital. He had done the State good service by the establishment of a training school for army midwives, which we greatly regret to learn is, since his death, likely to be abandoned. Dr. Spencer, of the Co. Donegal, who formerly held office as Assistant Librarian in the Irish College of Surgeons, Dr. Irvin, of Monaghan, Dr. Middleton, of Mullingar, and Dr. Kinane, of Templemore, and many other metropolitan and provincial practitioners of name make up, we regret to say, an unusually heavy obituary list for the year 1882.

Scotland.

THE ABERDEEN MEDICAL SCHOOL.

During the past year considerable changes have taken place in the Aberdeen Medical School, and movements have been inaugurated, and improvements accomplished which place both the student and teacher in more advantageous relations. In many respects the University of Aberdeen has an enviable pre-eminence over the other Scotch Universities, and notably in the number of bursaries available for industrious and necessitous students. It almost amounts to a truism that the latter are almost invariably the former. There are various Town Council bursaries available, and new bursaries in memory of Dr. Greig, of Fyvie, and Dr. William Milne have been founded; and only a few weeks ago, as recorded in our columns, £2,000 were given by Mrs. Marr, and £6,000 by Mr. Thompson, of Pitmedden, for the exclusive use of medical students. There are now about twenty medical bursaries, which, relatively to the number of students, is a considerable number. The munificence of Sir Erasmus Wilson has called a Pathological Chair into existence, which is worthily occupied by Professor Hamilton. An excellent laboratory has been formed in connection with the Chair, and eminent facilities thus afforded for the teaching of practical pathology, so far as it is possible to teach this subject in a laboratory. The Pathological Museum has been enriched by Professor Hamilton to such an extent that it may now be regarded as complete as any other department in the College. The class-rooms have all been made more comfortable by being heated by Perkin's hot water system. A new lecture-room has been provided for the Professor of Midwifery, and greater facilities have been afforded for the teaching of physiology. The anatomical department has been greatly extended, and the dissecting-room, museum, and osteology room, now *en suite*, may favourably compare with any similar apartments in the Kingdom. In the *personnel* of the College there have been the inevitable changes which even one year so often occasions. By the lamented death of Dr. Pirrie a vacancy took place in the Surgical

Chair, which has been filled up by an appointment highly acceptable to the profession, viz.,—that of Dr. Alexander Ogston, a gentleman in whose hands the well-earned surgical reputation of Aberdeen may be confidently entrusted. In room of Dr. Ewart, translated to a similar position in Edinburgh, Professor Alleyne Nicholson has been appointed; and St. Andrews receives in his stead Dr. Mackintosh, late of Murthly. The hospital staff remains unchanged. The managers have under consideration the desirability that the Professor of Pathology should have ready access to the materials afforded by the Infirmary. The question of additional infirmary accommodation is undergoing discussion, and it is felt expedient that special wards should be set aside for the treatment of skin diseases, diseases of women and children, &c. The weak point of the Aberdeen School is in the teaching of the final and practical subjects of the medical curriculum. The teaching in the wards of the Infirmary cannot be said to be worthy of the growing reputation of the School. In fact, the whole system of clinical instruction needs immediate and radical changes made in it; and the sooner this is done the better. At the forthcoming meeting of the managers the question of the appointment of an Assistant Physician will be discussed, and we sincerely hope that the selection of the candidate will not be guided by the wretched narrow-mindedness which in Aberdeen, as elsewhere, too frequently destroys the value of these appointments. The number of medical students enrolled this session is about 322, as against 297 last year.

BOOKS OF THE YEAR.

The following books, emanating from Scotland, appeared during the year, viz.:—The fourth edition of Husband's popular "Student's Handbook of Forensic Medicine and Medical Police." Hart and Barbour's "Manual of Gynaecology," a really good book; Byrom Bramwell's painstaking work "On Nervous Diseases;" "Spence's Surgery" (new edition); Wolfe "On Diseases and Injuries of the Eye," no less

ably than severely criticised in the *Glasgow Medical Journal* for May; a little work by Dr. James Wallace Anderson "On Nursing;" and Dr. James Patterson Cassell's translation of "Politzer's Text-Book on Diseases of the Ear and Adjacent Organs." Altogether, Scotland makes a very creditable appearance in the art of book-making for the year.

THE EDINBURGH MEDICAL SCHOOL.

The University of Edinburgh continues to maintain its undoubted numerical pre-eminence over the other Scotch Medical Schools. Up to this period in 1881 there were enrolled of medical students at the University of Edinburgh, 1,634, and up to the corresponding date in 1882 the large number of 1,728, being an increase on last year of no less than 94. In the teaching staff of the University changes have taken place. The vacancy caused by the lamented death of Professor Spence has been filled up, after a keen contest, by the appointment of Professor Chiene. This appointment has been a popular one with the profession; and here, at least, the selection of the Curators is homologated on all sides. Professor Cossar Ewart, of Aberdeen, has been appointed to the Chair of Natural History, by the unexpected resignation of Dr. E. Ray Lankester. The translation of Professor Hamilton to Aberdeen caused a vacancy in the office of Pathologist to the Infirmary, and to this position Dr. Byrom Bramwell has very justly succeeded. Professor Turner has been elected President of the College of Surgeons; and both he and the Colleges are determined to exert themselves to their utmost in retarding the question of medical reform, whose urgency is so universally recognised in the profession in Scotland, outside corporations, and the selfish leanings of other interested parties. It is suggested that the apparent apathy of the College of Surgeons is due to the fact that no changes can be made in its constitution without appealing to Parliament for a special charter, and that in the present state of affairs such an appeal might draw too much attention to the College. This we believe to be the true state of affairs. But the danger is more apparent than real. All the College is in need of is a little more honesty and openness in its management, a little less of the cringing attitude which it observes towards the University, and a little more consideration for the interests of the School on the reputation of which it lives. Surely the system by which the examiners elect themselves, and which in some cases is the means used to draw students to their classes, admits of improvement without an Act of Parliament. It is also worthy of remark that several home and colonial appointments of some value have of late been filled up by mere lads, who happened to be class assistants to one or two of the professors, whilst the extra-mural school has been totally overlooked. These boy-professors, who have never lectured nor taught the subject of their new chair but as class assistants to boys a few years their juniors, are suddenly placed in positions for which they are not prepared. The extra-mural teachers who have toiled for years naturally feel the slight placed upon them by the Colleges which do not support them as the University does its class assistants. High honours at the

University may be gained by any good short-hand writer with a good memory; for be it remembered that a medal only means that the receiver has reflected the crotchets of the professor. From this class are the class assistants taken. Now, we maintain that a professor needs a broader education than a class strait-jacket affords, and from which the extra-mural teacher is free. Scarcity of funds has arrested the progress of the University buildings. The cupidity of the University authorities has been made further manifest in their endeavour to subvert and render useless the teaching of pharmacy by the dispensaries, a function which they efficiently discharged—one dispensary for upwards of a hundred years, and another for the lengthened period of seventy. It is sincerely to be hoped that such manifestations of greed will only bring to greater prominence the pernicious nature and tendencies of the unjust monopolies enjoyed by the universities, and that the time is not far distant when they will be compelled to exist by fair and open competition with teachers receiving no State support, exclusive privilege, nor encouragement, and on the reputation of whom the University is founded; for it is the *School* and the comparative cheapness of the degrees that fills Edinburgh with students. Formerly, the subject of so-called "Practical Pharmacy" was taught in Glasgow by attendance in a druggist's shop or medical practitioner's dispensary, and in Edinburgh at the Royal and at the New Town Dispensary. Apart from the mechanical operation of compounding drugs, it is difficult to see how the teaching in the "Practical Pharmacy Class" of the University should not be overlapped by that of the systematic lectures; and it is equally incomprehensible what advantages can be claimed for the teaching thus enjoined over that obtained in the manner now assailed. In Edinburgh the Colleges very justly refuse to accept attendance on Professor Fraser's class in lieu of the dispensary pharmacy. There is some attempt being made to remedy an evil, which we have repeatedly denounced, with regard to the date of the first University examination. Hitherto the student has been obliged to wait eighteen months or two years before he was permitted to enter for his first professional. He will now be able to go up after one winter and summer session. The alteration, though tardily made, will prove a great boon to the student; and we congratulate ourselves on the share we have taken in bringing about the necessary reform. In a financial aspect, the College of Surgeons of Edinburgh has not been so successful in the Fellowship trade this year as during the previous one, the fees thus obtained being only £650, or nearly £400 less than in 1881. From the double qualification examination £1,300 have been received. Dr. Blair Cunningham has been appointed to the Statistical Office, but still retains his appointment as Curator of the College of Surgeons Museum. Dr. Patrick Heron Watson has been appointed Representative of the Royal College of Surgeons in room of the late Professor Spence. An important step has been taken by the Obstetrical Society in appointing a Pathological Committee to report on specimens presented at the meetings of the Society. Hitherto, the

products of disease have been simply placed on the table with merely a word or two as to their nature, no discussion taking place. A union of the Medico-Chirurgical and the Obstetrical Societies would be advantageous. It is understood that the Obstetrical is languishing from want of papers. This would naturally be inferred from the reception which it gave last year to certain papers from Glasgow. We think that a combined effort on the part of the different societies would be productive of work worthy of Edinburgh, an object which cannot be said to be at present accomplished. This union is, unfortunately, never likely to take place; the petty jealousies are too pronounced to admit of any combined action. We are sorry to state that the Students' Club has proved a failure, being unable to withstand the combined assaults of "piety," teetotalism, bad cooking, and—*sed vox faucibus harret*—dirt. This is much to be regretted, as such a club well conducted might have been productive of much benefit to the students. The present Bohemian life of the Edinburgh student is ill-adapted to foster that breadth of view, openness of heart, and refinement of feeling the want of which so frequently leads to those disgraceful and unseemly bickerings which injure the profession in the public mind.

THE MEDICAL PROFESSION AND NOTIFICATION OF INFECTIOUS DISEASES.

Certain clauses in the draft Glasgow Police Bill which have reference to the prevention and mitigation of disease have considerably exercised several Glasgow sanitarians quite recently; and meetings with reference to the question have been held in the Faculty Hall under the presidency of Dr. Scott Orr, and crochets have been fully aired in the Philosophical Society which is now the favourite arena for medical oratory and prelection in the city. Many circumstances contribute to this, and notably among others that this is a lay society, where the press being represented, full reports are given in the newspapers of the papers read and the discussion thereon, and it is evident that an opportunity for fame is thus presented which is eagerly seized on by the sagacious. It is supposed by not a few that these clauses so obnoxious to some, hardly merit the professional *furor* which they have begotten. It will at once be concluded by most people that as a profession the medical gratuitously contributes more information to the State, than any other, for the public good, and it seems ungracious to further impose upon it, in this respect, under pains and penalties of law. To the ample credit of the medical profession it cannot be gainsaid that it is ever as assiduous in its endeavour to prevent as to cure disease; and if it be disposed to refuse the imposition of additional gratuitous duty it cannot be said that it does so from disregard to the public weal. In Edinburgh, Dundee, and Greenock the notification of infectious diseases by the medical man or householder has been enforced since 1879, and it is not apparent that the condition of Glasgow in regard to epidemic disease, and where the knowledge of such disease is obtained by house-to-house visitation by sanitary inspectors, is worse than that of the above-mentioned towns. In the discussion at the Philosophi-

cal Society, on Dr. Ebenezer Duncan's paper, Professor Gairdner made some very cogent remarks. He himself was not at all unfavourable to notification. He thought it was most important for many reasons, that sanitary authorities should get the earliest possible information of everything that was going on bearing on the public health. That, he thought, was a first principle of sanitation. The real question was just whether the best way of securing that notification had been taken. The Edinburgh idea was a very plausible one indeed, but the real way of putting it was that it was simply paying the doctors to peach upon the people and the houses where epidemic disease existed. In that idea one fact was forgotten or excluded from consideration—namely, that sending for a doctor was a voluntary act, and it was precisely in those cases where it was most important to the public that notification should take place early that compulsory notification by a doctor would prevent the doctor being sent for. Thus the very means taken, as it were, to obtain the earliest information would in a great number of cases defeat the end that was desired. If he might make a random suggestion, he did not wish it to be considered that he was dictating the terms of an Act on the subject; as preferable form of notification to the one proposed in the Police Bill, it would be this—keep the compulsion on the householder if they liked, but instead of dragging in the doctor to "peach" upon the householder, with very imperfect results, let the sanitary authorities be instructed to offer, and let it be known to the whole population that they offered, a reward, not exceeding a shilling if they liked, to everybody who would give information of any case of infectious disease. Don't let a certificate be required; don't even require the disease to be named. No doubt a great many false informations would be got, but in such cases the shilling need not be paid. He would engage to say that if that course were adopted they would get a great deal more information in regard to these concealed cases than they would get from the doctors, for in many cases the doctor would never be called in, and the neighbours would always know. He was opposed to great blocks of buildings being erected for lodging-houses or for many families, without a bit of ground to be used as a play-ground being attached. He would also be very much inclined to say that, in no case, should large blocks of buildings for human habitation be erected without a suite of rooms being set apart in it as an hospital for the lodging of cases of disease. Dr. Russell, the Medical Officer of Health, was strongly biased in favour of the clauses in the draft bill. He had investigated many milk epidemics, and not a single case had occurred in which he would not have found it an advantage to have had such clauses. The notification clause did not originate with the Glasgow authorities. It was a clause which was taken by the Selecting Committee from the Manchester Provisional Order, and it was placed in that Provisional Order by the Local Government Board of England.

THE NEW HOSPITAL FOR SICK CHILDREN, GLASGOW.—While indiscriminate and excessive pampering of the working classes is calculated to make them forget, and

indifferent to the fact that they have social duties to discharge equally with the rich, we cheerfully admit that one of the least objectionable forms which an hospital can assume is that for the medical treatment of sick children. By certain philanthropic gentlemen the want of any such hospital was felt about twenty years ago, and since then steps have been taken with a view to the securing of such an Institution. The gentlemen who took up and endeavoured to carry out the scheme had a few difficulties to face, but all of these were in the course of time got over, and about a couple of years ago the committee set to work to get the hospital erected. The building has been proceeded with rapidly during the year now closing, and it is expected to be ready for the reception of patients on January 4th. Accommodation is provided for 55 in-patients, and the fittings, methods of ventilation and warming are carried out with all modern improvements. The staff as at present constituted is Drs. Leishman, Finlayson McEwen, Hector Cameron, and Walker, with Miss Harben, from the London Hospital for Sick Children as Lady Superintendent.

SCOTCH MEDICAL SCHOOLS.

GLASGOW UNIVERSITY.—1882 finds the Glasgow Medical School in an active and flourishing state. The number of medical students enrolled at the University is 823, against 624 last session. There is no change in the *personnel* of the teaching staff.

THE FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW, notwithstanding not a little and ungenerous assault, especially from the South of the Tweed, continues well to vindicate its *raison d'être*. In any new arrangement and distribution affecting the various licensing boards it is difficult to see how the claims of the Faculty cannot be regarded as substantial as those of the other Scotch qualifying bodies. Testimony to its popularity is afforded by the number of students presenting themselves before it for the preliminary and professional examinations. During 1882, the number of candidates for the preliminary examination was 296, and of these only 71 passed; at the primary professional examination 124, and of this number 53 passed; at the final examination 122, and of these 68 passed. In the matter of examinations some changes have been introduced in the direction of making the tests more practical and effective, and also more fair to the candidates. Formerly, any candidates *might* be called upon to dissect in presence of the examiners. Now, every candidate *must* dissect. Further, at the final examination it has been resolved to add an examination in operative surgery, this rule to come into operation in 1883. Other changes of less importance but pointing in the same direction will also take effect next year. In 1882 very extensive additions have been made to the Faculty Library, through the exertions of its courteous and intelligent Secretary, in the way not only of adding new books, but chiefly of filling up gaps in the older literature, especially that of France and Germany. A catalogue of the entire collection is now completed, and is in the hands of the printer. At the annual meeting in October, Dr. Scott Orr was re-elected to the office of President for another year, a position which he fills with marked courtesy and dignity. At the same meeting

vacant examinerships happening were keenly contested, with the result that the old examiners were re-appointed. These are so eagerly sought after, not alone in consequence of the direct emoluments of the office, but of the influence which extra-mural teachers thus influence over students. It is to be regretted that the rule was ever departed from at the Faculty that no teacher should hold the position of examiner. An impulse has been given to the rivalry in medical teaching in Glasgow by the new buildings in connection with

THE GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.—Some six years ago the managers of the Glasgow Royal Infirmary, considering the expediency of a medical school in connection with the Infirmary, obtained from the Government a supplementary charter, under which they appointed lecturers in the usual subjects of a medical curriculum. The accommodation at first provided for the school being found inadequate, by means of donations from private individuals new buildings have been erected worthy of the city, and eminently suitable for the purposes of teacher and student. Ninety students are in attendance on the school, and there are 110 clinical students at the Infirmary. The attendance at both is larger than last year; and the students are highly gratified at the accommodation provided for them in the School, which, we may add, was designed in the Italian style of architecture by Mr. James Thomson, with the intelligent assistance in practical details of Dr. Thomas, superintendent of the Infirmary. To the exertions of Mr. William McEwen, who has long taken a warm interest in the affairs of the Infirmary, the School is mainly indebted for the pecuniary support afforded by private gentlemen in the city. Their period of office having expired, Drs. Mather and Lawrie retired from the Dispensary, and to their positions Drs. Wallace Anderson and Dougall were promoted. Drs. Middleton, Henderson, Campbell Black, and Brock were appointed to subordinate positions on the Medical Dispensary staff during the year; and on the Surgical, Dr. Whitson having retired, his term of office having expired, Dr. W. G. Fleming was promoted, and Dr. Adams and Shaw appointed extra surgeons. Altogether the Glasgow Royal Infirmary maintains its high position as an unequalled field for medical study, and success in surgical and medical treatment.

ANDERSON'S MEDICAL COLLEGE shows more signs of vitality than ever, in spite of the attractions offered by the Royal Infirmary Medical School, and the pre-eminently aggressive school at the University gates. Its medical teachers are extremely anxious for a migration westwards, and it is only the *res angusta domi* which determines their continued habitation in George Street. We shall be pleased to see that the efforts which they are putting forth in this direction will be successful, and that a building be secured or built worthy of the reputation of this, the first Radical school (though now becoming respectably Conservative) of Glasgow.

THE NEW WESTERN MEDICAL SCHOOL is meeting with a fair measure of encouragement. Its first session was inaugurated by a somewhat bellicose address by Dr. MacVail. While we perfectly agreed with the sentiments, was it not possibly somewhat ungracious on the part of Dr. MacVail to level such philippics at the University at the

very time when it manifested such praiseworthy generosity towards the extra-mural teachers?

GLASGOW SOUTHERN HOSPITAL SCHEME.—Despite intelligent criticism of an adverse nature, the Glasgow Southern Hospital scheme is kept well alive by interested parties. To most thoughtful people the necessity for any such hospital is far from apparent, and it is confidently predicted (and it has been shown by Mr. William McEwen almost to a demonstration) that to be kept up by the South Side of the city the subscriptions at present received from this quarter for similar objects must be enormously increased. Excessive medical charity is one of the gravest questions of the day; the self-reliance of the working-classes is thus undermined, poverty and dissoluteness fostered, and a long-suffering and generally speaking underpaid profession shamefully robbed. As a consequence, in Glasgow, the working class practice of thirty or forty years ago has totally disappeared, and while the population of the city has enormously increased, the number of medical men is about the same as fifteen or twenty years ago. That there is a large section of the community between the pauper and the artisan class whose medical wants it is incumbent on the philanthropic and the humane to relieve, no one will gainsay; indeed, the attempt will have the sympathy of the entire profession; but we insist fearlessly, on the other hand, that it is not by absolute and unstinted eleemosynary aid that in the interests of society, no less than in the interests of the profession, this end ought to be achieved. The erection of another hospital in Glasgow, inviting *all and sundry* to receive *medical attendance and medicine* is a matter calling for the severest reprehension. Yet there are a few who benefit by such institutions, and whose interests blind them to the pernicious influences of unstinted charity, as they render them indifferent to the just claims of their brethren, and who by perseverance and commercial dash succeed in floating such schemes. Accordingly the committee in charge of the Southern Hospital scheme will soon be before the public, hat in hand, for funds, and with definite proposals as to size and style of buildings, &c., on which to base the charity refrain. It is stated that no fewer than forty-six sets of architects' plans have been lodged with the secretary, and that their variety is such that a considerable time must elapse before a final decision is arrived at regarding them. With this hospital and its objects we have no sympathy, believing as we do that, apart from the inevitable injury which it will inflict on the profession on the South side, and on the working classes, there will be the greatest possible difficulty in maintaining it, and that its partial maintenance can only be accomplished by draining chiefly from the Royal Infirmary the too paltry support which it receives from transpontine bounty.

SCOTCH MEDICAL SOCIETIES.

At the *Edinburgh Medico-Chirurgical Society* several important papers were read during the year, of which may be enumerated that of Dr. Lealie "On Hereditary Transmission of Disease;" Chien's paper on "Cranial Injuries;" Dr. Gibson's on the "Action of the Auricles in Health and Disease," in which, discussing the physiology of the auricles, reference was made to the advance

achieved by Lauder Brunton and others in bringing forward anew the fact of rhythmic pulsation of the great veins; a paper by Dr. W. Russell, of Carlisle, on the "Murmurs of Debility in the Pulmonary and Tricuspid Areas;" Dr. Clouston on "Alternation, Periodicity, and Relapse in Mental Disease;" Dr. Duncan on the "Treatment of Fresh Wounds," in the discussion of which it appeared that another new phase of the carbolic acid treatment had been entered upon in Edinburgh—viz., the abandonment of the gauze, and the substitution thereof of dry dressings in the shape of salicylic and carbolic wools; Dr. Cadell's paper on "Cases of Stricture of the Urethra," in which Holt's method of treating stricture was highly eulogised; and Dr. Allan Jamieson's paper on the "Treatment of Diphtheritic Sore-Throat," in which the use of a mixture of borax, boracic acid, and glycerine boiled together (boro-glyceride) was recommended. In the discussion upon this paper several of the speakers condemned the tendency to designate mild forms of sore-throat diphtheria, a custom which is certainly too common and much to be reprehended.

At the *Edinburgh Obstetrical Society* much good work was done. Prof. Simpson read an important paper on "The Uterine Sound," and, in commenting upon it, Dr. Donaldson, of Boston, very properly drew attention to the dangers of the sound in the bringing on of miscarriage accidentally, and the perforation of the uterine wall—the latter of which accidents had happened in his own hands, though no harm resulted. Dr. Matthews Duncan read a paper by Prof. Slavjansky, of St. Petersburg, on "The Development of Malignant from Non-Malignant Tumours of the Uterus," a paper which Prof. Simpson characterised as an able and interesting one, though he did not consider it proved that a malignant had developed from a non-malignant tumour. Dr. Croom read an instructive paper on "Funic Hæmorrhage during Labour." Dr. Popow, Pensa, Russia, contributed a paper on "Fibro-myxoma Duplex Ovariorum;" Dr. J. Halliday Croom, on "Clinical and Experimental Observations on the Bladder during Parturition;" Dr. Matthews Duncan, on "Fœtid Parametric and Perimetric Abscess;" Dr. Peter Young, on "Graviditas Serotina et Præcox," on which Dr. Croom held that the only test of protracted gestation is the weight of the child.

Of the notable papers read at the *Glasgow Medico-Chirurgical Society* may be mentioned Dr. Coats on "A Case of Spontaneous Lateral Sclerosis of the Cord," and one of Polio-myelitis Anterior;" Dr. Alexander Patterson, "Notes of a Case of Stone in the Bladder;" Dr. Hector C. Cameron, "Notes of some Cases of Unusual Surgical Diseases and Accidents." At the annual meeting of the Society held on the 6th October, 1882, Dr. W. T. Gairdner was elected President, *vice* Dr. George Buchanan, and Drs. Grieve and Alexander Robertson Vice-Presidents.

The *Glasgow Pathological and Clinical Society* receives considerable attention from the younger members of the profession, and many good papers were read at it during the year. The *Glasgow Southern Medical Society* was well attended during the same period; and its members are to be congratulated on the excellence of the papers read.

SCOTCH MEDICAL JOURNALS.

THE *Edinburgh Medical Journal* continues most worthily to represent current medical literature in Scotland. Its reviews are invariably able, and characterised by much fairness and evidences of careful examination. Its reports of the Medico-Chirurgical and the Obstetrical Societies of Edinburgh give an interesting *épitome* of the excellent work done in connection with these Societies. During the current year it contained many able original articles, of which may be mentioned Professor Grainger Stewart's "Introductory Lecture delivered at the Inauguration of the Practice of Physic Department of the New University Buildings;" Dr. D. B. Hart "On the Mechanism of Labour;" Dr. George W. Balfour "On the Position and Mechanism of the Hæmic Murmur;" Dr. G. A. Gibson "On the Action of the Auricles in Health and Disease;" Dr. T. S. Clouston "On Mental Diseases;" Mr. John Chiene "On Cranial Injuries;" Mr. Cathcart's interesting and instructing paper "On Some of the Older Schools of Anatomy connected with the Royal College of Surgeons, Edinburgh;" and many others of great merit. Altogether, the conductors of the *Edinburgh Medical Journal* are to be congratulated on its excellence for 1882.

Under the editorship of Drs. Coats and Napier, an impulse has been given in a praiseworthy direction to the *Glasgow Medical Journal* and while in a city like Glasgow, in which the profession feels the commercial spirit, and has consequently scant leisure to devote to literary pursuits, it is difficult to secure an adequate supply of interesting material, the object has been well achieved by Drs. Coats and Napier in 1882. The Western and the Royal Infirmarys furnish from their ample field instructive Clinical Records; the Proceedings of the Medico-Chirurgical and Pathological Societies are well reported in its pages; and it contains several papers of marked excellence. We may mention, for instance, Mr. J. L. Steven's paper "On a case of Pyelo-Nephritis with Micrococci;" "The Pathology of Diabetes Mellitus," by Dr. Coats; Professor Cleland's "Introductory Lecture at the Veterinary College;" and Dr. Alexander Patterson's "Statistics of the Glasgow Lock Hospital since its Foundation in 1805."

OBITUARY.

EIGHTEEN HUNDRED AND EIGHTY-TWO has removed from our ranks not a few well-known and honourable members, some full of years and honours, and others on the threshold of what promised to be happy, brilliant, and useful lives to mankind. In the death of ROBERT ORMOND, a veteran who held an honourable place among the practitioners of Edinburgh, has gone to his rest. Dr. Ormond died at the ripe age of 75. In consequence of failing health, Dr. Ormond had been for several years almost withdrawn from the public eye. During his long illness he had seasons of acute suffering, borne invariably with philosophic courage, patience, and meekness. Born in Orkney in 1806, he came South with his widowed mother and two brothers not long after the close of the Peninsular War, and received the greater part of his education in Edinburgh. Having chosen medicine as his future profession, he was in due time apprenticed to the late Dr. Adolphus Ross, then in partnership with Messrs. Bell and Russell, Fellows of the Royal College of Surgeons. He graduated in 1823, spent some time in studying on the Continent, and afterwards finally settled in Edinburgh. He became a F.R.C.S. Edin. in 1832, and in the course of years filled various positions in connection with the

College. Dr. Ormond was universally liked by his professional brethren on account of his unselfishness, his readiness to oblige, and his charming manner.

SIR ROBERT CHRISTISON, Bart., M.D.—A link which severed the present with the past generation of eminent medical men in Edinburgh—died on the 5th of February. For upwards of half a century he had occupied a prominent position in his profession, and in the scientific and social life of Edinburgh. As a teacher and as a writer his name was so widely known that it may truly be asserted that wherever the English language is spoken his loss was regarded as a signal one to scientific medicine. His strongly marked individuality presented always a model of uprightness and nobility of character, and exerted an influence which it is impossible to exaggerate in elevating the tone of the profession both in and out of Scotland. Dr. Christison was born on the 18th of July, 1797; his father, Mr. Alexander Christison, being for several years Professor of Humanity in the University of Edinburgh. Christison graduated M.D. in 1819, and desiring to extend his knowledge, proceeded to London, where he attached himself for several months to St. Bartholomew's Hospital; thence he proceeded to Paris, where he attended the lectures of Vauqueline and Thenard on Chemistry, of Gay-Lussac on Physics, and of Orfila on Toxicology. As illustrating the subsequent bias of his mind, it may be noted that he was a frequent visitor at the French Institute when Pelletier and Caventon announced their numerous discoveries on the subject of the chemical composition of vegetable substances, and especially on the separation and characters of the alkaloids. At the early age of twenty-five he was appointed Professor of Medical Jurisprudence in the University of Edinburgh, and ten years afterwards Dr. Christison was transferred to the Chair of *Materia Medica* which had become vacant by the death of Dr. Andrew Duncan. During the long period of fifty-five years he held the office of Professor, resigning his chair through temporary ill-health in 1877.

The town of Bathgate lost an appreciated public servant on the 5th of February in the death of Dr. JAMES BALFOUR KIRK. Dr. Kirk was born on the 6th of December, 1823, at Cairneyhill, near Dumfries, graduated M.D. in 1846, and for five-and-thirty years followed a large and exhausting practice in Bathgate and its neighbourhood. Dr. Kirk enjoyed in a large degree the confidence of his numerous patients, and the loss which the community sustained by his death was testified to by the manifestations of sorrow which then took place.

JOHN BROWN, M.D., LL.D., was born at Biggar on the 22nd Sept., 1810. His father was Secession Minister there, and superintended his son's education until 1822, when he was called to Edinburgh. After attending classes at the High School and the University, John Brown was apprenticed to Mr. Syme, and thus began the practical work of his profession at Minto House. Dr. John Brown will be remembered rather as a *littérateur* than as a medical man. His best known work is "Rab and His Friends." Amongst his earliest writings for the press are his criticisms in the *Witness* newspaper upon the pictures in the Exhibition of the Scottish Academy in 1846; an article "On Modern Painters" in the *North British Review*; and a paper on John Locke and Thomas Sydenham. In 1858 his *Horæ Subsecivæ* was published. In private life Dr. Brown was one of the most amiable and lovable of men; there was a charm in his manner and conversation which is quite indescribable, and a singular balance in all his faculties.

Scottish Surgery lost its acknowledged representative and head in the death of Professor JAMES SPENCE, who was born in Edinburgh on the 31st March, 1812. Amongst his first steps in his professional career was his being apprenticed to Messrs. Scott and Orr, an eminent firm of druggists then carrying on business in Edinburgh. On completing his medical education at the University and the Extra-Mural School, he obtained the diploma of the Royal College of Surgeons in 1832, at the age of 20 years. Previous to this, he spent some time in Paris, attending chiefly the surgical and the anatomical classes. In 1849 Mr. Spence became a Fellow of the Royal College of Surgeons; and in 1864, on the death of Professor Miller, he was elected Professor of Surgery in the University of Edinburgh; and in 1865 was appointed Surgeon in Ordinary to the Queen in Scotland. Mr. Spence was a distinguished surgical anatomist and operator, and was widely and deservedly respected in the profession. No one was more sympathetic nor tender-hearted than Mr. Spence, and operating by him was felt to be a strain on his nature. Unrewarded for years, he wrought honestly at his profession, and ultimately earned for himself a life of good report and signal success.

DR. GEORGE HAMILTON, of Falkirk, terminated an active and useful life on the 8th of July. Dr. Hamilton was born in Edinburgh in 1802. He was educated at the High School and the University of Edinburgh, and settled in Falkirk in 1833, where he remained for nearly half a century. He soon acquired an extensive practice, not only in Falkirk, but in the surrounding country. He was medical attendant to the Pleas Asylum, and to the National Imbecile Institution at Larbert. Dr. Hamilton had a ready pen, and was a constant contributor to the Edinburgh medical journals, while he also wrote on subjects outside the profession. He will be best remembered in the profession in connection with his earnest advocacy of the more frequent early use of the midwifery forceps. While no bigot, Dr. Hamilton was a keen politician, and invariably took a keen interest in politics. Dr. Hamilton had earned the gratitude of all the classes of Falkirk by his sustained and successful efforts to keep the Falkirk School of Arts in life and vigour. For a man of his years, Dr. Hamilton enjoyed great vigour of body, and till within a fortnight of his death was engaged on the duties of his practice. He was singularly happy in his domestic relations, and is survived by three sons, all in the medical profession, the second son being now Professor of Pathology at Aberdeen.

DR. CHARLES MOREHEAD, F.R.C.P., C.I.E., was first Principal of the Grant Medical College, India. He spent the latter years of his well-earned rest and leisure in Edinburgh, and the news of his sudden death came to many of the profession in Edinburgh as a personal affliction, for no one who enjoyed his friendship could help loving and admiring the polished, courteous gentleman who bore his load of years and honours so calmly and with such modest grace.

DR. WILLIAM ROBERTSON, F.R.C.P. Edin., died on the 25th August. He was born in Edinburgh in 1818, and was the son of the late Mr. George Robertson, Deputy Keeper of the Records in the General Register House. Dr. Robertson received his earlier education at the Edinburgh Academy, and his professional education at the University of Edinburgh, where he graduated in 1839. On the outbreak of the Crimean war he was appointed Inspecting Physician to the British Civil Hospital, Renkioi, and at this place and elsewhere he continued in the Government employment for eighteen months. He was one of the ordinary physicians to the Royal

Infirmary of Edinburgh, and in that position his diagnostic skill was held in high esteem. While the *Edinburgh Medical Journal* was under the conduct of a fraternity comprising Syme, Christison, Simpson, Bennett, and MacLagan, Dr. Robertson was chosen responsible editor of the journal, the duties of which office he filled with full acceptance to the conductors and readers. He was a man in all respects of excellent character.

By the death of Dr. ANDREW BUCHANAN, Glasgow lost one of the best known and esteemed members of the profession. Dr. Buchanan was a native of Glasgow, where he was born on the 10th of December, 1798. He was educated at the Grammar School and the University of Glasgow. Part of his medical curriculum was spent in Edinburgh. Subsequently he studied in Paris, and visited Italy. He graduated M.D. in the Glasgow University in 1822, and was admitted a Fellow of the Faculty in 1824. In 1823 he was appointed Professor of *Materia Medica* in the Andersonian University, and in 1835 one of the surgeons of the Royal Infirmary. He contributed largely to periodical medical literature, and was at one time editor of the *Glasgow Medical Journal*. In 1839 Dr. Buchanan was appointed to the chair of the Institutes of Medicine in the University, an office which he worthily filled till 1876. His chief reputation as a surgeon rests on his introduction of a new operation for lithotomy by means of a rectangular staff. Dr. Buchanan (of whom an exhaustive obituary notice appeared at the time of his death in these columns) was a highly-educated and accomplished gentleman, and was widely respected both in the profession and by a large circle of friends both in and out of Glasgow. He was an excellent and characteristic specimen of the high-class Scotch gentleman.

The untimely death of Dr. ROBERT PINKERTON caused a genuine feeling of sympathy for his bereaved family circle. He was born in Largs in 1848. He received his professional education at the University of Glasgow, where his career was one of uniform success. He took his degrees of M.B. and C.M. in 1876. On the outbreak of the Russo-Turkish War he was elected by Lord Blantyre to proceed to the seat of war as a member of the Red Crescent Society. In this capacity Dr. Pinkerton acted for several months, penetrating as far as Plevna. In 1879 he proceeded to New Zealand, in charge of the emigrant ship *Marlborough*; and he spent the winter of 1881 in Egypt. Dr. Pinkerton's career, thus cut short so early, promised to be one of honour and distinction, as he possessed enthusiasm for his profession and natural abilities which would not have failed to command success.

So recently as last month our columns contained an obituary notice of Professor PIRRIE, of Aberdeen, and it is unnecessary now to recapitulate what was then said of the loss sustained to this seat of learning.

CONCLUSION.

IN deploring the loss of such men as those referred to in the three divisions of the United Kingdom and on the Continent, we must remember that, while, by their genius some shed lustre on our profession, others by their personal character did more—they caused it to be respected and beloved. It is for us who sojourn after to look to them as beacons for our guidance, so that each may strive to the extent of his ability to obtain some measure of success in contributing to the good of mankind, and thus lead a happy and useful life.

In terminating our labours for another year—the forty-fourth—cordial thanks are due to our numerous subscribers and contributors; and in our future efforts, during such time as may remain to us, we bespeak their continued sym-

pathy and generous support. We are deeply sensible of the difficulty we set before us in desiring above all things to render the *Medical Press and Circular* a fair and impartial exponent of professional opinion above clique or party; and however much difference of opinion may be evoked, it will be our highest aim to conduct our duties so as to excite no unworthy personal hostility. Where many conflicting interests jar, and masked quackery is rampant, it is, no doubt, difficult to secure so desired an end. When influence

may frown down, and slander corrupt and pervert, a sense of duty alone, and a feeling of justice, support the public journalist. It is for him who fears scars to seek another place than the front of the battle, knowing well that the fruits of victory are better assured to him who wisely deems discretion the better part of valour. Still,

"He's truly valiant that can wisely suffer
The worst that man can breathe, and make his wrongs
His outides; to wear them like his raiment, carelessly;
And ne'er prefer his injuries to his heart,
To bring it into danger."

Foreign.

THE year that is now closing has, as well on the continent of Europe as in these realms, been at least on a par with those that have preceded it. There has been no falling off in activity, in unwearied industry, in intelligent prying into the secrets of Nature, in constant and varied endeavours, that have not been altogether in vain, for the prevention and cure of disease, for the "alleviation of human suffering and the prolongation of human life."

MEDICAL SCHOOLS.

In our brief and necessarily imperfect Retrospect of the past year, we will commence with the medical schools and the changes that have taken place in their professional staffs. First in importance comes the retirement of the venerable and renowned Langenbeck from the Chair of Surgery and the Directorship of the Clinical Institute of Surgery in Berlin, the Father of Conservative Surgery as he was called in Germany. He himself succeeded Dieffenbach, who in his turn succeeded Gräfe. Before the time of the last named, Germany scarcely possessed what could be called a School of Surgery, and was contented to look up to Larrey and Dupuytren as the fountains, *par excellence*, of surgical knowledge. The coveted prize thus left for competition by Langenbeck's retirement has been secured by Professor Bergmann, late of Würzburg, but not until it had been offered to Billroth, of Vienna, a man not less distinguished where anything is known of surgery as a science, than his late *confrères* and former teacher of Berlin. The prize was a tempting one, but after a short struggle Billroth gladdened the hearts of his adopted countrymen (he is a Prussian by birth) by the announcement that he decided to stay with them. Bergmann delivered his inaugural address at Berlin on Nov. 1st.

The next, perhaps in importance, is Nothnagel's transference from Jena to Vienna, as the successor of Duchek. No doubt need be entertained of his fitness for the post, and of the certainty that he will sustain the reputation of the school. In 1870 Nothnagel was privat-docent in Berlin, where he published his "*Lehrbuch der Arzneimittellehre*," "*Das Deutsche Archiv für Klinische Medizin*," &c. From that time he has been an indefatigable worker and writer. His principal work "*Topische Diagnostik der Gehirnerkrankheiten*," was published in 1879, a work that speaks volumes for the writer's patience and exactitude, for it is a clinical study in which not a single observation has been considered worthy of a place unless verified by post-mortem examination.

The Chair of Pathological Anatomy in Vienna, rendered vacant by the death of Rokitsky, it was fondly hoped, by the profession, would be offered to Klebs, the celebrated Prague physician, but the Minister for Educational, Spiritual, and Medical Affairs decided to offer it to Professor Kundrat. This virtual refusal of a position to which he was undoubtedly entitled,

made Klebs willing to leave Austria, where his services had met with such scanty recognition. Switzerland was only too glad of an opportunity of obtaining possession of such a distinguished teacher, and offered him the Chair of Pathological Anatomy of Zurich, it was accepted by him, notwithstanding an address from the students of the Prague University, with an appeal that he would not leave them in the time of their need. Chiari has succeeded Klebs at Prague.

Professor Paul Voigt has succeeded Hüter at Griefswald.

Mikwlici, of Vienna, an assistant of Billroth's, has accepted the post of Professor of Surgery at Cracow.

Professor Eulenburg, of Griefswald, not finding the teaching faculties to his mind, and further, discovering that he was powerless to alter the conditions of things, has given up the Professorship, and settled in practice in Berlin.

Professor Rossbach, of Würzburg, has been called to succeed Nothnagel at Jena. Rossbach is not unknown to our readers, as we gave, in these columns but a short time ago, a summary of his experiments on the secretion of mucus.

Kitz, of Halle, has been appointed to the Professorship of Anatomy in Berlin.

The above are some, but only a part, of the translations that have taken place during the past year. Movement from one University to another more renowned, is the rule in Germany, so that a vacancy in the professional staff in Berlin, will set in motion a whole series of changes, in which half the universities in Germany will have been in turn affected.

WORK AT THE SOCIETIES.

THE meetings of the various local societies have again been characterised by the solid and original character of the work brought before them. This cannot be better shown than by a brief—very brief—*résumé* of some of the work done.

First in importance, without the shadow of a doubt, ranks the discovery of the

BACILLUS OF TUBERCLE,

first made known to the world in an address, destined to hold its place in history, delivered before the Physiological Society of Berlin, on March 24th of the present year. On the 5th of April we gave the first notice of this important discovery to our readers—but this by the way. Villemin was the first to discover the inoculability of tubercle. There were not wanting many scientific men who were sceptical as to the results of Villemin's experiments. They said that rabbits and guinea-pigs were peculiarly prone to tuberculosis, and that it could be produced in them at any time by setons or by inoculation, with almost any foreign material. Others more philosophical took care to repeat the

discoverer's experiments before committing themselves. First Cohnheim, and then Salomonsen, carried out inoculations successfully, and after them von Baumgarten, with a like result. Then Tappeiner experimented with inhalations, and it was finally settled that for the future tuberculosis must take its place as an infectious disease. Being satisfied in his own mind as to the nature of the disease, Dr. Robert Koch set himself the task of proving the existence of some parasitical foreign body that might possibly be the cause of it. As a matter of fact, he succeeded in his task, by discovering, by the help of a certain process of colouring (now well known, and since improved upon), characteristic bacteria, till then unknown, in all organs changed by tubercle, "The bacteria thus made visible by the new process" (we quote from his address) "have a rod-like form and thus belong to the group of the bacilli. They are very thin, and are from a quarter to half as long as the diameter of a red blood-corpuscle; occasionally they attain to a greater length, even to that of the full diameter of a blood-corpuscle." He found the bacilli in eleven cases of miliary tuberculosis; in twelve cases of caseous bronchitis and pneumonia. In animals he found it in eleven cases of "grapes," in three apes, which died of spontaneous tubercle; in nine guinea-pigs and nine rabbits, also dead of spontaneous phthisis. Besides the above, Koch inoculated with tubercle 172 guinea-pigs, 33 rabbits, and 5 cats, and in every case succeeded in finding bacilli in the lungs of the animals thus inoculated. Our space will not permit us to follow further the various steps by which he proved that these particular organisms are the accompaniments of no other disease, and that they are not merely the accompaniments of tuberculosis, but the originators of it. Suffice it to say that each step is as thoroughly and as philosophically worked out as the first. We should not have said this much at this period of time after the discovery were it not that many people look upon it with a complacent incredulity, not unmixed with a sort of pity for the poor creatures that believe in such new-fangled ideas.

But we must pass on, and be more brief.

Amongst the important subjects discussed may be mentioned Iodoform, Puerperal Fever, and Diphtheria. These were brought before the Berlin Medical Society, the debate on diphtheria extending over two or three nights. The annual congresses offer perhaps on the whole more points of interest for a retrospect than the ordinary meetings of societies. One of the first, if not the first of the year, was the Medical Congress which met at Wiesbaden on April 20th, under the presidency of Frerichs. It is to be understood that this was a Medical Congress exclusively, surgery and all the other branches of medicine being excluded. About 200 physicians attended. Professors Leyden and Rosenstein both read papers on the same subject—viz., Bright's Disease. Both readers agreed that there is but one type of nephritis, that the parenchymatous and the interstitial are in the main not to be distinguished; that out of the infectious form, the second stage of fatty degeneration, as well as that of the third, shrivelled kidney, could be developed. On the same day Koch demonstrated the bacillus of tubercle to the Congress. The following day the antipyretic method of treatment was discussed, when most of the speakers, among whom were Liebermeister (who opened the discussion), Jürgenson, Curschmann, Prof. Binz and Riess, spoke more or less in favour of the treatment by baths. The usual banquet closed the session.

The Eleventh Congress of German Surgeons was held in Berlin from May 31st to June 3rd, under the presidency of Langenbeck. As a summary of the work done has already

appeared in these columns, we will content ourselves by referring to one of the subjects only—viz., Movable Kidney. E. Hahn, of Berlin, read a paper on this subject, or rather on the operation for fixation of movable kidney, and exhibited a patient. The existence of such an affection was certainly not pooh-poohed. Herr Landau was opposed to operation, but on theoretical grounds only. Küster had operated once with relief to the patient. Esmarch had had three cases in which operation gave relief to the symptoms.

The fifty-fifth meeting of the Society of Naturalists and Physicians was held at Eisenach from Sept. 18th to 22nd. The meeting was formally opened in presence of the Archduke and Archduchess of Saxe-Weimar. The opening address by Hückel, of Jena, which was said to be brilliant, was a consideration of the views of Goethe, Lamarck, and Darwin. A very interesting discussion on the feeding of infants was introduced by a paper by Biedert, of Hagenau, and another on compulsory vaccination, that was rendered more interesting by the fact that it was introduced by the well-known apostle of non-compulsion, Dr. Oidtman, of Linnich. One of the sectional papers was by Professor Bergmann, of Würzburg, now Langenbeck's successor in Berlin, on "The Present Method of Wound-dressing, and its relation to Anti-sepsis." He points out to his German audience that the foundations of our present knowledge regarding asepsis were laid in the observations of Billroth, whilst an assistant in Langenbeck's wards, of the very different courses run by open and closed wounds, that where the skin covering is complete, inflammation regularly and of necessity is absent; that it is the drop of pus, or the drop of putrescent matter upon which an inflammation depends. "Step by step," he says, "have these processes and relations been definitely worked out by German surgeons, and it is their work that has prescribed to surgical therapeutics its task—the so-called antiseptics. It was certainly Lister's good fortune in his experiments to hit upon a method of treatment by which the process of decomposition was disturbed, but he never succeeded in solving the problem of antiseptics." After this passage it will be readily conceived that it remained to German surgeons to solve the mystery. The success of the treatment was undoubted, but "the scientific mind of German surgeons strove against accepting the results of a method of treatment as a proof of the correctness of a theory. But during the last ten years everything is changed; we are now able to prove it outside the body, as the *materielle* of disinfection are better understood." There seems to be a narrowness of tone about all this that seems scarcely in harmony with the great position the speaker has been chosen to fill. Something of the same runs through his inaugural address delivered in Berlin on November 1st, although in that he does acknowledge that German surgery has only taken the position it now occupies during recent years. The meeting, on the whole, was a great success, there being about eight hundred visitors present. The main object of these *réunions* was kept in mind, viz., the forming acquaintance and renewal of acquaintanceship with men with whose names as writers and men of eminence they might be perfectly familiar, but from whom, but for the opportunities afforded by these gatherings, the exigencies of life would for ever keep them asunder.

As is the custom in Germany, other societies had held their meetings in the same town immediately before the session of the Naturalists and Physicians, so that the lingerers from the meeting of the Society of Alienists met the early arrivals of scientists belonging to another branch.

The fourth Hygienic Congress met in Geneva from Sep-

tember 4th to 9th. The Congress took a fairly extended view of the region embraced by Hygiene; nor did it confine itself to the merely human aspects of the subject, as veterinary hygiene formed a department.

NEW DRUGS.

FOREMOST amongst these must be mentioned one that is not by any means new, but one the recent revival of which has become so widely spread that the literature relating to it, that has appeared during the past year only, would fill many volumes. We refer to Iodoform. First discovered about the year 1823, its virtues were hidden till but a very few years ago, when Mosetig and others began to employ and praise it. It has grown so rapidly into favour that it is now made use of in the most varied diseases—from syphilis and tubercle to ulcer of the stomach and diabetes, eye affections, and decayed teeth. Hoffer has written on its action on blood corpuscles; Mook on iodoform in tuberculosis; Scherr and Benzan on iodoform in diphtheria, Deutschmann, Schindler, and Grossmann on iodoform in eye diseases, Binz on the emigration of white blood corpuscles during iodoform administration, Neumann and Thomann on iodoform injections in syphilis. The list of authors who have written about the drug would be tedious to read. Certainly no one therapeutic agent has received so much attention during the past year as iodoform.

CONVALLARIA MAJALIS is a remedy that for generations has been in repute in Russia, but has only recently been subjected to scientific scrutiny. MM. Germain Sée and Deplat, the former especially, have laid the profession under obligations to them by investigating the powers of the drug. It seems to have an action almost identical with that of digitalis—may be given in doses of from one gramme to a gramme and a-half daily in the form of aqueous extract of the whole plant. Its diuretic action is spoken of as being certain and pronounced in all cases of cardiac dropsy, less so in dropsy depending on kidney disease, and *nil* when the cause lies in the liver.

PARALDEHYD.—V. Cervello has been studying the action of this preparation, and according to his report published in the *Archiv für exper-Pathologie und Pharmacologie*, it is likely to prove a useful addition to our materia medica. It is a modification of aldehyd, is a colourless fluid that boils at 124° C., and is soluble in eight parts of water at 13° C. Paraldehyd diminishes cutaneous sensibility, but reflex irritability remains intact even in hypnotic doses, but not in doses that are fatal. Injected subcutaneously it causes pain, but produces the same effects as if absorbed through the stomach. The dose is three times that of chloral hydrate.

ADONIS VERNALIS.—The active principle of this plant has been obtained also by Cervello and experimented upon. He found its action to be similar to that of digitaline, but that the dose required was much smaller. In rabbits and dogs the blood pressure always rises under its influence. He does not appear to have tried its effects on human beings.

GUACHAMACA.—Portions of the guachamaca plant were supposed to be first brought to Europe by Dr. Karl Sachs on his return from Venezuela, in which country the most wonderful stories are told concerning its virtues. It is not mentioned by A. v. Humboldt, whence it is concluded that it was not, at the time the distinguished traveller was there, known medicinally. Herr Schiffer, of Berlin, has been studying its effects, and brought them before the notice of the Society of Physicians of Berlin last spring. It acts very much like curare, in allaying spasm, and in large doses causing a general paresis. The juice taken from the plant in the rainy

season makes the most powerful extract. If ten mgrm. of the extract are given to a frog, an interval of fifteen to eighteen minutes passes before any effect is noticed. After this period, however, the action is rapid. The animal becomes stupid, allows the head to fall, permits itself to be laid on its back, and does not draw back the leg if extended, &c. So far its action is exactly similar to that of curare; but now comes the difference. The respiration continues, the circulation and cardiac activity are undisturbed. Its effect was tried on a young man in Frerich's Klinik who was suffering from cramps. Ten mgrm. of the extract were injected, but for three quarters of an hour no effect was observed. The patient then, in broad daylight, suddenly fell into a rather deep sleep, which lasted for nearly three hours; respiration and circulation were undisturbed. Schiffer believes that in guachamaca we have an agent capable of combating disorder of the motory apparatus, as well as a useful hypnotic.

MISCELLANEOUS.

BURNING OF THE BERLIN EXHIBITION FOR GERMAN HYGIENE AND LIFE-SAVING.

This Exhibition was to be as perfect and complete as science, art, and lavish expenditure of money and labour could make it, that is, perfect as a German Exhibition, for it was not intended that it should be anything but German. Here the most valuable and unreplaceable objects, unique of their kind, the ornament and pride of museums, apparatus to the discovery and perfecting of which the inventors had devoted a lifetime, were to be formally introduced to the world. The German Imperial Crown Prince was to honour the Exhibition by declaring it open. But, as is not unusual, the arrangements for the opening, which was fixed for the 16th of May, were rather backward, so that the work had to be hurried on at break-neck speed day and night. In the midst of this incautious hurry and bustle, on the 12th of May, just four days before the intended opening, the building was accidentally set on fire, and in a few minutes the whole well-nigh completed work with all its invaluable contents was destroyed, "and with it the hopes which the whole scientific and educational world had formed that the undertaking should be an honour to Germany and a benefit to all mankind."

The tercentenary of the founding of the Maximilian University of Würzburg was celebrated during the past year. The celebration addresses were not all of the character common to such occasions; some were of a practical nature, that of Rossbach for instance, on the secretion of mucus being the outcome of patient investigation.

The custom of holding vacation classes for study has not been departed from, and during the past autumn the numbers of practising medical men who assembled for study in the various educational centres showed no signs of falling off.

Here may be mentioned the opening of a new Lying-in Institution for Vienna, intended to be a place of instruction more especially for practising physicians. All Austrian practitioners of medicine will have the right of making use of it as a place of study.

During the past medical year the number of men who have passed the State examination in Prussia alone was 303. Above one-third, and less than one-half of them were already Doctors of Medicine. The Doctorate does not confer a licence to practise as with us, but is simply an honorary titular distinction, as it was here until the Act of

1858 gave it a legal importance it did not previously possess. Although only a minority of those passing the only examination required by the State are doctors at the time, they nearly all graduate afterwards, sooner or later.

NEW OPERATIONS.

The operation for fixation of wandering kidney, of which mention has been already made in connection with the eleventh Congress of German Surgeons, may rank as one of the newest—one cannot yet call it a triumph—attempts in abdominal surgery. A recent French writer seems to look upon every new operation as a kind of Moloch whom it is necessary to propitiate by offering it the blood of innocent victims. We fear that in the present instance victims will be offered up without propitiating the idol. The operation has been performed at least four or five times with a certain amount of success, as the operators aver; but as we are in ignorance as to the gravity of the symptoms that seemed to render such an operation needful, we are scarcely in a position to properly or intelligently appraise the success.

LUNG SURGERY.—W. Koch (who must not be confounded with Dr. R. Koch), a surgeon of Dorpat, in cases of localised affections of the lungs has attempted treatment by operation. In two cases of gangrene he resected the rib over the affected part, and then applied the thermo-cautery, plunging it into the lung tissue. Some improvement seems to have resulted, but perhaps scarcely as much as may be enough to justify frequent repetitions of a formidable operation in one and the same case.

RESECTION OF THE PYLORUS has been performed several times during the past year. It has, in fact, become so frequently performed, that Billroth has thought it necessary to sound a note of warning against a too frequent recurrence to such a grave operation. He now thinks that its performance should be limited to non-malignant stricture of the pyloric orifice of the stomach.

BOOKS.

As usual, the number of books appearing during the year has been enormous, whilst new editions of many old favourites have been published.

A very important work that has taken long to accomplish, although many hands have been employed on it, is Pitha and Billroth's "*Handbuch der Allgemeinen und speciellen Chirurgie.*" More than forty professors and distinguished men have taken part in its compilation. The first part appeared in 1865; the last part has just been published, and is, we believe, the second half of the late Dr. Mayerhofer's contribution ("*Die Entwicklungsfehler und Entzündungen des Uterus Sterilität*"). The whole work forms, in fact, a complete system of surgery, but each author's contribution is published separately, and may be bought separately if desired, except in a few instances. It is published by Enke, Stuttgart. A fourth edition of Zeissl's "*Lehrbuch der Syphilis*" has appeared. The Vienna Professor has, in this edition, had the assistance of his son Dr. Maximilian Zeissl. Professors Chiari and Schrötter have also taken part in the work. A second edition of Cohnheim's "*Allgemeine Pathologie*" has appeared. Also a sixth edition of Bock's "*Anatomie der Anatomie des Menschen.*" Hegar has published the "*Life of J. P. Semmelweis,*" with an account of his teaching. J. Rigler has published a "*Life of Hahnemann,*" which is said to be very entertaining (Hirschwald, Berlin). A few others may be mentioned out of a large number of valuable works—"Atlas Topographique du Cerveau et des Localisations Cérébrales," Gavoy (O. Doin, Paris); Hyrtl, "*Lehrbuch der*

Anatomie der Menschen," sixteenth edition (Vienna, Braumüller); Ziemmsen I. Bd. 4 Theil, "*Allgemeine Therapie,*" Spiegeberg *Geburtshilfe,* second edition; Stellwag V. Carion, "*Lehrbuch der Practische Augenheilkunde,*" fifth edition; Charpentier "*Traité Pratique des Accouchements.*" Tome I.; "*Dictionnaire de Médecine et de Chirurgie Pratique,*" Jaccoud (Baillière and Son, Paris). Of English authors whose works have been translated during the past year we may mention Huxley ("*Science Lectures*"), Tyndall ("*Les Microbes*"), Swain ("*Surgeon's Vade-Mecum*"), Bramwell ("*Diseases of the Spinal Cord*"), McLagan ("*Rheumatism: its Nature, &c.*"), Spencer Wells ("*Tumours of the Ovary and Uterus*"), and Sir Henry Thompson ("*Lithotomy and Lithotripsy*").

OBITUARY.

As might have been expected, death has not been idle. Men of ripe years and riper reputations have passed away full of honours, and younger men in the prime of life have not been spared.

Amongst the older men, THEODOR VON BISCHOFF has just passed away (Nov. 5th), aged 75. In the spring of the present year he celebrated his Doctor's Jubilee, when he received the congratulations of the King of Bavaria, together with a decorative order, and also addresses and congratulatory telegrams from Strasburg, Vienna, Kiel, Bonn, Prague, Leipzig, Halle, and several other universities. A native of Hanover, he studied natural sciences and medicine in Bonn and Heidelberg. In 1833 was privat-docent at the Obstetrical Institution; in 1836, extraordinary professor of comparative and pathological anatomy at Heidelberg. In 1843 he became ordinary professor. He was afterwards professor of physiology and anatomy at Giessen. In 1855 he removed once more to Munich, where he fulfilled the same duties as at Giessen, and where he remained till his retirement in 1878. He is best known by his histories of the development of the various mammalia.

PROFESSOR C. HUTER died at the early age of 44, but not before he had made his mark amongst the learned men of the day. At the time of his death he was professor of surgery at Griefswald. The foundations of his special knowledge were laid in the pathological institute and in the surgical Klinik at Berlin as assistant to Professors Virchow and Langenbeck. His works, "*Allgemeine Chirurgie*" and his "*Gelenkkrankheiten,*" testify to his spirit of research and to his devotion to his calling.

PROFESSOR FRIEDREICH, of Heidelberg, is amongst the number that have departed. He has been succeeded by Gerhardt, of Würzburg.

DR. KARL MAYERHOFER, the gynecologist, is another of the juniors stricken down in his prime (46). He was a professor extraordinary at the University of Vienna, and "an ornament to the medical faculty." Some years ago he was called away to Russia to attend a noble Russian family. His fame had, however, preceded him, and in a very short time his services were in request from St. Petersburg to the Caucasus. It is said of him, as of many other right-minded members of our profession, that "he was a noble and unselfish man, who devoted as much care to the poor who were under his charge as to the rich." His latest literary work—which, indeed, first saw the light after its author's departure—was *Lieferung 2, Band iv., 1 Abtheilung* of the "*Handbuch der Allgemeinen und Speciellen Chirurgie,*" edited by Von Pitha and Billroth, comprising the chapters on *Entwicklungsfehler & Entzündungen des Uterus & Sterilität, parts 1 and 2.*

IRISH POOR-LAW INTELLIGENCE.

ABSTRACT OF THE REPORT OF THE LOCAL GOVERNMENT BOARD FOR IRELAND.

We submit our tenth annual report relating to our proceedings up to the 31st March, 1882. In our report for 1881 we noticed the fluctuation in the number of persons who received relief in the five previous years. The number had been increasing in each successive year since 1877, and reached the maximum in the year ended February, 1881, when the average daily number of persons relieved in the workhouses during the year amounted to 53,796, and the average daily number on out-door relief to 60,883; but we are glad now to be able to report a change in the other direction, the average daily number of workhouse inmates in the last year, ended February, 1882, having been less by 1,024 than in the previous year, and the average daily number on out-door relief having diminished by 687.

In our two last annual reports we referred to the proceedings of our Board, and of Boards of Guardians, in carrying out the measures that had been adopted to meet the exceptional distress which had prevailed in parts of Ireland since the winter of 1879-80, and we are now in a position to state, with much satisfaction, that all those temporary measures have ceased to be necessary, and that the relief administered in the ordinary manner has been found sufficient to meet the wants of the poor during the past winter.

The power to authorise exceptional out-door relief under the Relief of Distress Act expired on the 1st of March, 1881 (except in the cases of the families of persons detained under the provisions of the Protection of Person and Property Act), and out-door relief to the able-bodied classes may now be given in any union only when the workhouse is full, or when it is unfit for the reception of poor persons by reason of fever or infectious disease. We felt it right to make an order in the month of March last, under sec. 2 of the Act 10 Vic., cap. 31, authorising such relief in the Waterford Union, where there was a serious outbreak of small-pox, and our inspector reported that almost every department of the workhouse was as full as was desirable, considering the prevalence of fever and small-pox; but it has not been necessary to adopt that course during the past winter in any other union in Ireland.

We reported to your Excellency in 1881 that we had found it necessary to dissolve the boards of guardians in three unions, viz., Belmullet, Swineford, and Newport, and to appoint paid officers to carry into execution the provisions of the Poor-law Acts. In all these unions the vice-guardians have now ceased to act, and the boards of guardians were reinstated at the time of the annual election of guardians last month.

A decrease of 6,604 has taken place in the total number admitted in sickness during the year, the decrease in the number suffering from fever and other dangerous contagious diseases having been 1,806, but that there was an increase of 2,984 in the number admitted who were not sick.

Deaths by fever were 552, as against 758; by lung disease, 2,317, as against 2,323; and deaths by small-pox 64, as against 97 in last year.

The number of orphans and deserted children put out to nurse from the workhouses in Ireland, under the provisions of the Act 39 and 40 Vic., c. 33, extending the legal age

from 10 years to 13 years, on the 4th February last was 2,339, an increase of 96 over the number in the preceding year.

FINANCIAL STATISTICS OF YEAR ENDED 29TH SEPTEMBER, 1881.

There has been an increase of £28,463 in "out-door relief;" an increase of £1,982 in "salaries and rations of officers," and an increase of £21,149 in "all other expenses," making a total increase of £51,594, from which is to be deducted a decrease of £16,212 in "in-maintenance and clothing," and a decrease of £221 in the "cost of relief for deaf, dumb, and blind," being a total decrease of £16,433, leaving a net increase of £35,161.

TREASURY SUBSIDIES.

The following is a statement of the Parliamentary grant for medical and educational purposes, and for salaries under the "Public Health (Ireland) Act," for the year ended 25th March, 1881:—

	Amount allowed for the Year.	
	£	s. d.
Medical purposes ...	73,080	7 11
Educational purposes ...	9,755	7 10
Total for Medical and Educational purposes ...	82,835	15 9
For Salaries under Public Health Act ...	13,716	1 11
Total ...	96,551	17 8

The total amount allowed under the Parliamentary grant for medical and educational purposes for the year ended 25th March, 1881, namely, £82,835 15s. 9d., is £470 4s. 0d. more than the amount for the previous year.

The amount for salaries under Public Health (Ireland) Act, namely, £13,716 1s. 11d., is £182 12s. 3d. less than for the previous year.

While the total expenditure of poor rates, for all purposes, viz., relief, medical relief, burial-grounds, registration of births, deaths, and marriages, sanitary measures, expenses under Superannuation Act, payments under Cattle Disease (Animals) Acts, and under National School Teachers Act, was, in 1880, £1,187,248, making a poundage of 1s. 8½d. on the valuation, the expenditure in 1881 for those purposes was £1,251,617, being an increase in the total expenditure of £64,369, and making a poundage of the expenditure on the valuation of 1s. 9½d.

The current sanitary expenditure for the year was £48,918, in comparison with £51,927 in the previous year.

MEDICAL CHARITIES ACT, AND VACCINATION ACTS.

In Ulster there has been a decrease of 10,087 cases prescribed for at the dispensaries, and a decrease of 5,357 of those attended at their own houses.

In Munster there has been a decrease of 17,239 cases prescribed for at the dispensaries, and of 7,797 of those attended at their own houses.

In Leinster there has been a decrease of 20,299 cases prescribed for at the dispensaries, and a decrease of 6,896 of those attended at their own houses.

In Connaught there has been a decrease of 6,634 cases prescribed for at the dispensaries, and a decrease of 2,609 of those attended at their own houses.

It will be seen by the particulars in our annual report for 1881, that there had been a net increase of 37,155 in the number of cases throughout Ireland in 1880, as compared with the previous year, and it is satisfactory to observe that there was a marked decrease in the cases for the year 1881.

VACCINE DEPARTMENT.

During the year ended 31st March, 1882, 3,512 applications have been received from medical officers of workhouses and dispensaries, and other public institutions, from military medical officers stationed in Ireland, and from private practitioners, for lymph, and 16,144 points, and 3,096 tubes charged with lymph were distributed. During the same period 3,783 vaccinations have been performed at the stations in Sackville Street and York Street, Dublin.

The deaths from small-pox in workhouses in 1881 are less by thirty-three than the number in 1880. The number of cases treated in dispensary districts under the Medical Charities Act being 749 less than in the previous year.

Since (1881) there has been, during the first quarter of the year 1882, an outbreak of small-pox in Belfast Union of considerable extent, and also an outbreak of less extent in Waterford Union and in Armagh Union.

There were 3,782 cases of scarlatina treated by medical officers of dispensary districts in 1881, against 4,835 in 1880, being a decrease of 1,053.

There was a considerable outbreak of measles in the Dublin district, commencing in October, 1881, and the following Table gives the number of cases:—

Number treated by Medical Officers of Dispensary Districts from 1st Oct., 1881, to 1st April, 1882	2,750
Treated in the two Workhouses, .	295

Number recovered, ...	2,457
-----------------------------	-------

„ died, ...	356
-------------------	-----

Remaining under treatment April 1st,	142
--------------------------------------	-----

2,750

295

2,955

2,955

The following shows in detail, and under the usual heads a comparative statement of the expenditure for the two years ended September 29th, 1880 and 1881 respectively:—

MEDICAL CHARITIES EXPENDITURE.

	1880. £	1881. £
1. Medicines and medical appliances, ...	27,003	29,092
2. Rent of Dispensary buildings, ...	8,189	8,386
3. Books, forms, stationery, printing and advertising, ...	1,101	1,203
4. Salaries of { Medical Officers, ...	88,922	88,819
{ Apothecaries, ...	2,700	2,711
5. Fuel, porters, and incidental expenses, ...	11,253	13,891

EXPENSES UNDER VACCINATION ACTS.

6. Vaccination fees and other expenses:—		
Fees to Medical Officers, ...	13,140	12,088
Other expenses, ...	1,067	1,054

Total, ...	£153,875	£157,244
------------------	----------	----------

PROVIDING DISPENSARY-HOUSES AND DWELLING-HOUSES.

In connection with the administration of the Medical Charities Act we refer here, in continuation of our previous report, to the "Act to give facilities for providing dispensary houses and dwelling houses for medical officers of dispensary districts in certain parts of Ireland," which received the Royal Assent on the 21st of July, 1879.

A general disposition continues to be shown to take advantage of the provisions of the Act, and proceedings under it are still pending in several cases.

A CASE of phosphorus poisoning is recorded, in which a woman in order to come into the possession of a large inheritance, poisoned a boy aged 15 by introducing the ends of phosphorus matches into the rectum.

It is stated that no appointment will be made to the Chair of Animal Morphology in the University of Cambridge, rendered vacant by the death of Mr. F. M. Balfour.

INQUEST IN THE WATERFORD ASYLUM.

An inquest was held in the asylum on the body of an old woman named Mary Farrell, aged 70 years, who died recently.

Dr. Atkins sworn—This patient was a married woman, 70 years of age; she was admitted here on the 10th June, 1882, on a magistrate's warrant, as a dangerous lunatic; she was very feeble and broken down on admission; I made a special report to the board on her case; she then appeared to be suffering from heart affection; since then her physical condition improved under care, but she was always very restless, and unless constantly watched would never sit quiet; her mental condition was *dementia*; on yesterday morning, at twenty minutes to eight o'clock, I was summoned to see her; they thought she was dying; I went at once and found her lying on the floor of the hospital pavilion dressed, covered with blankets, and a bolster under her head; she was quite unconscious and breathing slowly; she had a cut on the left eyebrow, skin deep, and was almost pulseless; I made inquiry as to how it happened; the nurse in charge, Bridget Flynn, said deceased was got up as usual and was brought to the hospital by the attendant; as she was passing a door post she made a clutch at it and fell, dragging down the attendant by her weight; she fell on the floor and that cut her eye; she died in forty minutes.

To the Coroner.—The attendant is a very good-tempered woman; I can't say, without a post-mortem examination, if she fell through heart disease or a sudden weakness; she was a very difficult patient; I think she died from a nervous shock, caused by the fall. Was there a step where she fell?—No; she had passed the step, and was on the level.

The Coroner—I hope there was no violence used?—I believe not; however, the attendants will speak for themselves; she was rather a case for the union hospital than this house; she came from Dungarvan, and I reported she was dying when she was admitted.

Bridget Flynn sworn—I took her from nurse Ford; she told me to treat her carefully; the nurse had helped me to dress her. Did the deceased make any objection to leave the cell?—A little; I had no trouble in getting her out of the cell; we had some trouble in dressing her. How did you get her along?—Nurse Ford helped me to take her part of the way, and then just as the nurse left us I had a hold of deceased by the back, and she suddenly fell, and I fell beside her; her face was out by the fall; I called the nurse, who came at once; she said to lift her up, that it was nothing; we both lifted her up, and I saw the cut on her eye; she was not able to stand, and we carried her up to the hospital. What was done for her there?—I don't know; nurse Ford sent for the doctor.

To Mr. Lyons—She had passed the steps when she fell; she was not trying to come back when she fell.

Anne Ford sworn—I am head nurse in the institution; deceased was troublesome on yesterday morning when one of the attendants was dressing her; I went and held her hands while the girl put the petticoats over her; there were four steps going up from where she was dressed, and I put her over them with Bridget Flynn; I said to Flynn—"Take care of her, now, and bring her up to Jane;" I had not well turned my back when deceased fell; she frequently fell on her back and stiffened out; on this occasion I did not at first think the fall was out of the usual way. How long was she lying on the floor?—Just while I turned; Jane Roche took charge of her in the hospital, where she was brought at once.

To Mr. Lyons—She never fell in the corridor before; when I saw her she was cut; I sent for the matron.

Dr. Atkins—And she sent for me at once. I am quite satisfied there was no violence used to the deceased. When I saw her I had the priest sent for, as I knew she would not live.

Jane Roche was examined, and said when deceased was brought to her she was very bad, and witness sent for the doctor, who came in three minutes, and ordered her brandy and water; she died within an hour.

The jury found that death arose from shock to the system, caused by a fall.

CORRESPONDENCE.

SUPERANNUATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With your permission I would unofficially offer a few remarks on Dr. Leatham's letter which appeared in the Supplement to your issue of 12th July. The Poor-law Medical Officers' Superannuation Bill, drafted by the Council of the Irish Medical Association, proposed that the granting of reasonable superannuation allowances in all proper cases should be made compulsory on boards of guardians.

Comparison of the terms of that Bill with those of the Government Bill now before Parliament, both of which are set forth in *extenso* in recent Reports of the Association, and careful perusal of the observations contained in the reports respecting them, will, I think, satisfy all Poor-law medical officers that they can offer no reasonable objection to the proposals of the Association; but, unfortunately, neither the Government nor the majority of the Irish Members of Parliament, as representing boards of guardians, quite concur in the views of the Association and those of the medical officers.

The Government Bill, as stated in the last Annual Report of the Association, proposed that the discretionary right of granting pensions shall be transferred from the guardians to the Local Government Board; but, since the introduction of the measure Government has pledged itself to reverse that principle, and leave the discretion of granting pensions still in the hands of the guardians, subject, however, to an appeal to the Local Government Board. The objections offered by the Council to this change are fully explained in the Reports of the Association, and need not now be reiterated.

No objection to any of the terms of their Bill has been communicated to the Council of the Association by any medical officer or member of the Association; the Council must, therefore, I think continue to adhere to the principles of the Bill suggested by them. And after further perusal of the two Bills and the Reports of the Association, I opine Dr. Leatham will not consider any of the Council's proposals extreme or in any degree unreasonable.

The Association warmly advocates compulsory superannuation, or, if that cannot be obtained (and there is but little reason to expect it can), then a system which shall practically be compulsory in all proper cases.

There is no precedent in the public service for granting retiring allowances to any but permanently disabled officers, unless to those whose age exceeds sixty years, or whose period of service has reached forty years; and the Council found it necessary to omit such a proposal.

The Council would gladly see a right to pension upon retirement conferred on all medical officers after twenty years' service, irrespective of their condition as to fitness to continue to discharge their duties; but they are advised that an attempt to obtain such a provision from Parliament would be fatal to the Bill.

Nor is there precedent in the public service for granting under any circumstances a pension exceeding three-fourths of an officer's official income, unless in the case of heads of departments.

Anyone who feels that an addition of twenty years to the period of his actual service, for the purpose of

computing his superannuation allowance excessive, has in his own power a right to decline to receive whatever amount he considers excessive. The rule of the public service in the case of professional officers is that a number of years *not exceeding twenty* may be so added, and no public servant need scruple accepting what the Legislature declares him entitled to; but there is very little reason to expect that the maximum of additional years will be made respective to Poor-law medical officers.

Dr. Leatham next touches on the subject of fees for examining dangerous lunatics, and observes that he has often remarked the Irish Medical Association takes great credit to itself for the passing of the Act which provides for the examination of dangerous lunatics; but he evidently has not carefully perused the Reports of the Association, or he could not be so grievously mistaken in making such a statement. That Act was passed, despite the remonstrances of the Association that it was unjust to require dispensary medical officers *without fee or reward* to examine and certify as to the condition of alleged dangerous lunatics. What the Association takes credit for is that it obtained the *payment of fees for such examinations*, whether the person was found to be a dangerous lunatic or not—a duty previously imposed on dispensary medical officers without the possibility of remuneration.

I am glad to hear that Dr. Leatham has been a subscriber to the Association ever since its commencement, which was forty-three years ago. I have only to regret that there are now so few living who can say as much, and that his good example has not been more generally followed.

Dr. Leatham next pays a well-merited compliment to the successful efforts of the Association in the interests of Poor-law medical officers especially, which affords me the occasion to say with regret that if the bulk of Poor-law medical officers themselves would only evince as much interest in their welfare as the Association does, their position and emoluments could with little difficulty be greatly benefited; but so long as the Association is supported by about only one-half of the Poor-law medical officers, while the other half freely accept the benefits towards the acquisition of which they have not contributed, the wonder is that so much, not so little, has been achieved.

Were it not for the philanthropic support which the Association has met with from those who can never expect any benefit from its operations, and the devoted services and attention of the official members of the Association, the great majority of whom have no personal interest beyond an ardent desire to benefit others, the position and emoluments of the Poor-law medical officers would assuredly have remained what they were originally. The benefits conferred by the Association upon Poor-law medical officers can best be estimated by a comparison of their position and emoluments forty years ago with those of the present time. Every change for the better, and no change for the worse, I unhesitatingly assert was due, and due solely, to the exertions of the Irish Medical Association.

I fear I have already trespassed at too great length, and crave your forgiveness for so doing; but I would comment on one other point in Dr. Leatham's letter, while thanking you for your kind indulgence, and him for affording me the opportunity of correcting errors which possibly may exist in other minds than his—viz., he suggests that some means should be taken to bring under the notice of all the dispensary committees in Ireland the fact that issuers of carelessly or improperly issued tickets for dispensary medical relief are liable for payment of fees upon such tickets being cancelled. But Dr. Leatham must have forgotten that a few years ago the Association sent to the hon. sec. of every dispensary committee in Ireland a circular clearly and fully pointing out the abuses of the present system, and warning all persons authorised to issue tickets who

did not properly exercise that privilege that they thereupon become liable to be sued by the medical officer for the amount of his fees.

The circular to which I refer was quickly followed by the issue of a circular by the Local Government Board, calling the special attention of members of dispensary committees, and others authorised to issue tickets, to the very serious abuse of the system which arises through their negligence, and strongly advising that due care and discrimination should in all instances be exercised to prevent abuse.

Dr. Leatham, like many others, seems to think the Poor-law Medical Service a branch of the Civil Service, and therefore entitled to all its advantages, such as leave of absence each year, which he mentions; but, unfortunately, the Poor-law Medical Service is not a branch of the Civil Service—there are many, myself included, who would be glad if it were; and possibly the time is not very remote when it shall be made so.

I am, yours faithfully, JOHN H. CHAPMAN.
60 Pembroke Road, Dublin,
July 22nd, 1882.

RED TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some time ago I saw a letter on the above subject in your columns, written by Dr. Somerville, medical officer of Union Hall dispensary district, in which he truly stated that the indiscriminate manner in which these tickets can be presented at any time of the day or night is an abuse of medical relief, and of medical men. I can endorse every word that Dr. Somerville wrote on the subject, and his experience of going over the same ground two or three times in the day, simply on account of an improper system, is similar to mine. I have frequently received red tickets at 9 or 10 o'clock at night, requiring me to see patients who had been sick for weeks or months, and in whom no urgent symptoms rendered my presence more needful than it had been at any time during the illness, but became desirable simply on account of some sudden freak of the patient or his friends. In fact, in these cases the convenience of the patient's friends alone is consulted, and that of the doctor is not considered for one moment.

The remedy lies in the direction pointed out by Dr. Somerville, viz., the making it compulsory to present all red tickets, urgent ones excepted, before a certain hour in the day. This plan would not entail a hardship on our patients, as we could be called at any time—day or night—to cases for which our presence is quickly required, while in other cases the tickets could be as easily sent to us at or before a certain fixed hour, as black ones are at present presented to us at the dispensary.

The directions on the backs of our red tickets undoubtedly show that the desirability of some such regulation is tacitly admitted, inasmuch as they bear the following sentence:—"This ticket should be presented as soon after it has been obtained as practicable." But this is by no means invariably done, nor are we freed from responsibility by the neglect or indifference of the bearer; neither is the procurer of a ticket required to obtain it at as early an hour in the day as he can, which would be a much more important regulation than the incomplete and practically useless suggestions now given.

In one point only do I differ from Dr. Somerville, viz., as to the final hour for presentation of tickets. Ten o'clock I consider too early in the day for persons living in remote parts, and would suggest 12 as a much better hour, and one that could not inconvenience anyone.

Now that Dr. Somerville has touched on this question I hope his professional brethren will not be silent on the matter, but will give their opinions on the point publicly in your journal, as a prelude to some practical step for the removal of this abuse.—I am, &c.,

Bandon.

J. J. WELPHY, M.D.

CERTIFYING DANGEROUS LUNATICS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly let me know in "Answers to Correspondents" in your next issue of the *Medical Press* how I am to act under the following circumstances:—A dangerous lunatic residing in the dispensary district of which I am medical officer is brought before two justices of the peace, who call in the aid of a neighbouring dispensary doctor and sign the necessary certificates for committal, quite ignoring my services altogether, at the same time filling up in the blank spaces for particulars that the doctor who examined the lunatic was medical officer of the district in which the lunatic resided, mentioning the name of the district. Now, as I am the only doctor of the district, I wish to know if I can take any steps to recover the fees I should be legally entitled to, or to prevent a repetition of the injustice? An answer in your next will much oblige,

Yours truly,

SUBSCRIBER.

[You cannot, of course, recover any fee, but the transaction is altogether illegal, and, if you lay the circumstances before the L.G.B. they will probably disallow the payment and prevent repetition of the transaction.—Ed.]

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF JUNE, 1882.

- June 2nd.—Hunt, J. G.; Kilmacthomas, co. Waterford; Lic. R. Coll. Surg. Irel. 1881.
5th.—Keenan, J.; Mercer's Hospital, Dublin; Lic. R. Coll. Surg. Irel. 1881.

29th.—McCabe, J.; Cavan; Lic. R. Coll. Surg. Irel. 1882.

PORTAFERRY DISPENSARY DISTRICT.

An election for a medical officer took place last week in the vacancy caused by the decease of Dr. Alexander Filson. There were eight applicants, and a poll having been taken, it was found that there was a tie between two of the candidates, Messrs. Dunne and Hastings, each having polled seven votes, so that a fresh election must take place.

MALLOW UNION.

An advertisement for a medical officer to Doneraile Dispensary District was recently issued, the salary stated being £120 per annum. Dr. O'Riordan was elected, but the guardians reduced his income to £100 a year. The Local Government Board have been appealed to, and they very properly refused to sanction the reduction, and the salary will remain at £120.

IRISH POOR-LAW INTELLIGENCE.

UNION OFFICERS' SUPERANNUATION BILL.

THE following is the evidence of the Vice-President of the Local Government Board, as reported by the *Freeman's Journal*:—

Mr. H. A. Robinson was the first witness examined. He considered that a reform of the present system of granting pensions to union officers was necessary, on the main ground that owing to the present arrangement, by which such officers were granted pensions or not at the discretion of the guardians, and had no way of knowing positively whether they would receive any allowance at all on retirement, many officers, long after they are able to discharge their duties efficiently, are induced to remain in the service.

The Solicitor-General—Are you aware whether any board of guardians have set down any fixed rule as to the superannuation of these officers? They cannot make any fixed rule, because one board of guardians could not influence the actions of any future board. They may have an understanding amongst themselves on the subject, but upon that he was unable to express any opinion. Several boards were now refusing to give pensions which at one time did give them, and there were ten unions in Ireland which never gave them.

To Mr. Findlater—He thought the adoption of the Civil Service scale would generally remove the dissatisfaction naturally existing amongst union officers.

To Mr. Callan—I have seen an amended Act prepared by the union officers. Was still of opinion that the Act as originally introduced was in its best form; it would save the trouble of correspondence.

Now, discarding the saving of correspondence to a well-paid official board, is that its principal recommendation? I have no objection to the amendments proposed.

Have not the hardships of which you complain been in existence for many years, and did you issue any remonstrance to the boards of guardians until they showed an inclination to be too generous to their officers? We issued no general circular, but I would not say that we sent no remonstrance in any case. The circular was dated 25th November, 1881.

You issued it, then, not on account of the hardships endured by the officers, but on economical grounds? To a great extent on economical grounds.

As long as the boards of guardians were doing injustice you issued no circular? We issued no circular until the one I have mentioned. We proposed to adopt the Civil Service scale for pensions for the officers.

Does not the Civil Service permit the admission of officers at the age of 16, and are union officers admitted before 21? Unless with the permission of our board.

Now, as a matter of fact, do boards of guardians really care for officers under 30 years of age. Certainly there are officers younger. Could not say that they elected clerks or masters under 30 years of age, or any

officers except schoolmasters. He could not say what the pay of doctors in the army or navy was, but he thought they were in receipt of larger pay than union medical officers. The union doctors were gentlemen of quite as good position as army or navy doctors.

To Mr. Weldon—The amount of superannuation granted in many cases up to the issue of the circular of November, 1881, was disproportionate to the service of the officers. The personal popularity of union officers with the board during whose existence they retired determined to a great extent the amount of pension granted. He would not object to have the Civil Service scale granted in all particulars, if the power of increasing or reducing the pensions were left with his board. If that power were not given, the Local Government Board would be compelled either to stop the whole allowance, or sanction the full amount granted.

Mr. Healy—Do you propose to adopt what you call the Civil Service scale of pensions merely for want of a better? No; but because I thought it would be fair to all parties.

You admitted, in reply to Mr. Callan, that the scale you propose as the Civil Service scale differs actually from it in three important particulars—namely, in the insertion of the words “not exceeding,” the age at which the officers are admitted, and the pay, and that the only part in which the Civil Service scale is retained is in the mere mechanical matter of “sixtieths” in computing the rate at which the allowance is to be estimated? Yes, it differs in those respects from the Civil Service scale.

The whole of the teachers' salaries and half the medical officers' salaries are paid by the State? Yes.

Yet the Bill proposes that the whole of the pensions in both those cases should fall upon the ratepayers? That merely continues the existing practice.

But the existing practice might be to give no pensions at all, while in future they will be compulsory? The fact that the State has been generous towards the local ratepayers in these respects should not now be held to constitute a reason for extending the principle.

You expect that a national rate of an eighth of a penny in the pound will meet all charges for pensions under the bill? Yes, for the next ten or fifteen years, excluding the first year, when it might reach a farthing.

Are you aware that the English School Board Act was passed under the representation that a fractional poundage would also defray all expenses, while now the school rate has reached sixpence in the pound in many places? I have no experience on that point.

But would you be willing in this Bill to have it enacted that the pension rate shall never exceed a farthing? Yes, a further application to Parliament being made, if required. As he stated before, he would have no objection to the adoption of the Civil Service scale as far as the omission of the words “not exceeding” went, if the power of reducing or increasing the pensions granted by the board of guardians in special cases were left with

the Local Government Board. The Bill as it stood proposed to vest in the Local Government Board the power to add on a certain number of years to the service of some classes of union officers in estimating the pension to which they would be entitled. The master, the clerk, and the doctors would be the only officers, so far as he believed, who would receive the advantage of the provision. The Local Government Board consisted of three members, one of whom was a medical man. They were appointed by the Crown without examination of any kind. He thought it was a question for Parliament to decide whether they could confer upon the gentlemen composing this board the power of vetoing the action of the boards of guardians. They asked for that power as the best way out of the difficulty, and it was for Parliament to decide whether it should be conferred upon them or not.

To Mr. Biggar—The veterinary inspectors would not come under this Bill, as they were appointed by the Lord Lieutenant. In sixteen cases the Belfast guardians had refused to grant superannuation allowances. He did not know whether those individuals deserved a pension or not, as the merits of the case did not come before the Local Government Board unless the guardians granted a pension. His board, however, knew pretty well the character of all union officers in Ireland, especially the important ones; as, if they are proved inefficient, or if any complaint is substantiated against them, a record is kept at his office. He could not say whether the guardians were better qualified to form an opinion on the deserts of an officer than the Local Government Board. The guardians certainly had more continuous observations of their conduct. He would not undertake to say whether the guardians, who were on the spot, and who paid the officers, were the persons best entitled to judge as to whether the officers were deserving of superannuation allowances, as that raised the whole question of the system upon which boards of guardians in Ireland are at present controlled.

To Mr. Daly—The power sought by the Local Government Board in Ireland to compel boards of guardians to grant pensions to the officers was not possessed by the English Local Government Board. It was a question for Parliament to decide whether that power would be granted or not, but he, as a member of the Local Government Board who promoted this Bill, of course approved of it. He was aware that rate collectors in many places had business besides their duties as rate collectors which occupied more of their time.

Are you aware that in Cork the greater part of the duties of collection are performed by deputy-collectors? I was not aware of that fact.

Taking into account that the election of guardians is annual, that the proceedings are published, and that the guardians are conversant with the officers' duties, I wish to ask you whether these gentlemen of the 163 unions in Ireland are not better judges of the efficiency of their officers than a body of gentlemen resident in Dublin who can never judge of the manner in which those duties are discharged unless by official reports or by observation at a distance? In my opinion any officer who discharges his duties sufficiently satisfactorily to remain in office, that officer is entitled to superannuation.

To Mr. Justin M'Carthy—The main reason given by the Local Government Board for the Bill is because they refused to pension officers. The Board assumed they were wrong in most cases, because they held those officers performed their duties satisfactorily and were entitled to pension.

M. A. VOLLANT ("Cosmos les Mondes") produces the effects of grafting by a simple transfusion of the sap of the desired variety of fruit tree into a suitable stock. He gives his process the very ill-chosen name of "vaccination of plants."

CORRESPONDENCE.

SANITARY PROSECUTION FEES.

TO THE EDITOR.

SIR,—By order of the board of guardians, I, as medical officer of health, attended Petty Sessions in this town, and gave evidence in a sanitary prosecution case. I made application for my fee to the presiding Justice (a gentleman who is disposed to give the fullest allowance to medical witnesses), but he stated he was unable to give a guinea fee, as the rent of the premises complained of was under £2 per annum, and allowed me half a guinea. The P. S. Clerk stated the Justice has no power to issue an order, and wrote a recommendation for half a guinea, a copy of which is the following:—

"THE BOARD OF GUARDIANS v. JOHN COSGROVE.

"I hereby certify that Dr. Buchanan was examined before me as a necessary witness in the hearing of a case under the Public Health Act, and I hereby recommend that the sum of 10s. 6d. be paid to him out of the poor rate for expenses.

"Dated at Arva this 26th day of July, 1882.

"Presiding Justice."

Kindly inform me if there is a fixed allowance for medical witnesses in such cases, irrespective of the value or rent of the premises complained of, sanctioned by the L. G. B., and if the Justice has power to issue an order for the amount.

I am, Sir, yours, &c.,

L. BUCHANAN, M.B.

[Under section 258 of the Public Health Act every officer of a sanitary authority shall attend and assist in any prosecution instituted by such authority on receipt of an order from such authority so to attend: Provided always, that if a medical officer of the sanitary authority shall so attend and assist, he shall be entitled to remuneration from the sanitary authority at such rate as the L. G. B. shall approve, unless it shall have been agreed that the duty of affording such attendance and assistance shall be included in his salary, or that his whole time shall be occupied in the discharge of the duties of his office. The fee, therefore, needs no certificate or recommendation, and must be paid by the guardians on application.—ED.]

THE ABUSE OF RED TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following case, heard at the Quarter Sessions, Kilmainham, may be interesting to dispensary medical officers:—

November last I was doing duty for Dr. Davy, of the Crumlin and Terenure dispensaries. At the Crumlin dispensary, I was handed a red ticket, signed by Mr. Michael Lyons, to visit a child named Goodbody, residing at 8 Rutland Avenue, Crumlin. I paid the visit, and was surprised on inquiry to find that the father of the child was a foreman miller, and also that it was outside the district I was in charge of. On those grounds, I had the ticket cancelled by the dispensary committee, and wrote to Mr. Lyons for my fee, £1 1s. Mr. Lyons paid no attention to two letters I wrote him on the subject, so I placed the case in the hands of a solicitor, and it came before the Recorder on the 5th of this month. The defence put forward was that I should have known the district, and was not obliged to attend. The Recorder ruled otherwise, and stated that it was a monstrous thing

that ill-paid men like dispensary medical officers should be compelled to visit out of their district through the carelessness of the ticket issuer, and he would grant a decree for the amount, with costs.

Faithfully yours,

CHARLES JONES.

60 Rathgar Road, Dublin.

LIST OF ENTRIES IN THE REGISTER OF THE
BRANCH MEDICAL COUNCIL (IRELAND) FOR THE
MONTH OF JULY, 1882.

- JULY 1st.—Fisher, G. H. J.; Rathmines; Lic. R. Coll. Surg. Irel. 1882.
3rd.—Law, W. F.; 2 Elgin Road, Dublin; M.B. Univ. Dub. 1882, Bach. Surg. Univ. Dub., 1882.
5th.—Bradshaw, T. R.; Haddington Road, Dublin; M.B. & M.D. Univ. Dub. 1882.
5th.—Smith, T. R. M.; Belfast; M.B. & B.Ch. Univ. Dub. 1882.
6th.—Porter, G. C.; Dalkey; Lic. K. Q. Coll. Phys. Irel. 1882, Lic. R. Coll. Surg. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
10th.—Dunning, C. E.; Sligo; Lic. R. Coll. Surg. Irel. 1881, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. R. Coll. Surg. Irel. 1882.
11th.—Russell, G. B.; Borrisokane; M.B. & B.Ch. Univ. Dub. 1882.
12th.—Jennings, M.; Kildysert, co. Clare; M.D. Roy. Univ. Irel. 1881.
12th.—Seymour, J. N.; Newcastle, co. Down; M.B. and B.Ch. Univ. Dub. 1882.
18th.—Barre, W. V.; Glasnevin, co. Dublin; Lic. R. Coll. Surg. Irel. 1882.
14th.—Cahel, E. B.; Peter Place, Dublin; Lic. R. Coll. Surg. Irel. 1881, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
14th.—Maguire, C. J. D.; Cong, Mayo; M.D. R. Univ. Irel. 1882, M.Ch. R. Univ. Irel. 1882.
15th.—Norris, F. B.; Kilworth, Cork; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.
15th.—Stronge, Samuel; Belfast; M.D. R. Univ. Irel. 1882.
15th.—Robinson, L.; M.Ch. R. Univ. Irel., 1782.
15th.—Robinson, L.; Maison de Santé, Dublin; M.D. R. Univ. Irel. 1882, M.Ch. R. Univ. Irel. 1882.
15th.—Moore, F. H.; Cootehill; Lic. R. Coll. Surg. Irel. 1882, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
17th.—Whelan, J. H.; Loughrea; M.D. R. Univ. Irel. 1882, M.Ch. Surg. R. Univ. Irel. 1882.
18th.—Morris, J. A.; Dublin; Lic. R. Coll. Surg. Irel. 1881.
19th.—Magner, T.; Newcastle, W.; Lic. K. Q. Coll. Phys. Irel. 1881, Lic. Mid. K. Q. Coll. Phys. Irel. 1881, Lic. R. Coll. Surg. Irel. 1881.
19th.—Daly, J. P.; Cork; M.D. R. Univ. Irel. 1882, M.Ch. R. Univ. Irel. 1882.
19th.—McGuinness, J. H. O'D.; Ballina; Lic. R. Coll. Surg. Irel. 1881, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
19th.—Burke, E. McW.; Claremorris, co. Mayo; Lic. R. Coll. Surg. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
20th.—Hadden, W. E.; Skibbereen, co. Cork; M.D. R. Univ. Irel. 1882, M.Ch. R. Univ. Irel. 1882.
20th.—Hearn, M. L.; New Ross; Lic. R. Coll. Surg. Irel. 1881, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
21st.—Moloney, C.; Murroe, co. Limerick; L.A.H. Dub. 1879, Lic. R. Coll. Phys. Edin. 1881, Lic. R. Coll. Surg. Edin. 1881.
21st.—Carson, J. S.; Lansdowne Road, Dublin; M.B. Univ. Dub. 1882, M.Ch. Univ. Dub. 1882.
22nd.—Gillespie, T. R.; Lansdowne Road, Dublin; M.B. Univ. Dub. 1881, B.Ch. Univ. Dub. 1882.
22nd.—Maguire, B.; Rathdown; Lic. R. Coll. Surg. Irel. 1881.
24th.—Dickinson, A. N.; 11 Upper Merrion Street; Lic. R. Coll. Surg. Irel. 1879, Lic. K. Q. Coll. Phys. Irel. 1880.

- 25th.—Tynan, J. H.; Edgeworthstown; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.
25th.—Chute, J.; Tralee; M.B. Univ. Dub. 1882, M.Ch. Univ. Dub. 1882.
28th.—Cowley, T. J.; Bandon; M.D. R. Univ. Irel. 1882.
28th.—Doyle, M.Ch. R. Univ. Irel. 1882.
28th.—Doyle, J. I. P.; Ballysalla; Lic. R. Coll. Surg. Irel. 1881, Lic. K. Q. Coll. Phys. Irel. 1882.
28th.—Gillmore, R. W.; Dublin; Lic. R. Coll. Surg. Irel. 1882.

RED AND BLACK TICKETS IN 1881-2.

IN Ulster there has been a decrease of 10,087 cases prescribed for at the dispensaries, and a decrease of 5,357 of those attended at their own houses.

IN Munster there has been a decrease of 17,239 cases prescribed for at the dispensaries, and of 7,797 of those attended at their own houses.

IN Leinster there has been a decrease of 20,299 cases prescribed for at the dispensaries, and a decrease of 6,896 of those attended at their own houses.

IN Connaught there has been a decrease of 6,634 cases prescribed for at the dispensaries, and a decrease of 2,609 of those attended at their own houses.

That there had been a net increase of 37,155 in the number of cases throughout Ireland in 1880, as compared with the previous year, and it is satisfactory to observe that there was a marked decrease in the cases for the year 1881.

VACCINE-LYMPH DISTRIBUTION.

THE Director of the Vaccine Department of the Local Government Board reports that during the year ended 31st March, 1882, 3,512 applications have been received from medical officers of workhouses and dispensaries, and other public institutions, from military medical officers stationed in Ireland, and from private practitioners, for lymph, and 16,144 points and 3,096 tubes charged with lymph were distributed. During the same period 3,783 vaccinations have been performed at the stations in Sackville Street and York Street, Dublin.

The deaths from small-pox in workhouses in 1881 are less by thirty-three than the number in 1880. The number of cases treated in dispensary districts under the Medical Charities Act being 749 less than in the previous year.

Since 1881 there has been, during the first quarter of the year 1882, an outbreak of small-pox in Belfast Union of considerable extent, and also an outbreak of less extent in Waterford Union and in Armagh Union.

PUBLIC EXPENDITURE ON IRISH PAUPERISM.

THE following is a statement of the Parliamentary grant for medical and educational purposes, and for salaries under the "Public Health (Ireland) Act," for the year ended 25th March, 1881:—

	Amount allowed for the year.		
	£	s.	d.
Medical purposes ...	73,080	7	11
Educational purposes ...	9,755	7	10
Total for Medical and Educational purposes	82,835	15	9
For Salaries under Public Health Act	13,716	1	11
Total ...	96,551	17	8

The total amount allowed under the Parliamentary grant for medical and educational purposes for the year ended 25th March, 1881, namely, £82,835 15s. 9d., is £470 4s. 0d. more than the amount for the previous year.

The amount for salaries under Public Health (Ireland) Act, namely, £13,716 *ls.* 11*d.*, is £132 12*s.* 3*d.* less than for the previous year.

While the total expenditure of poor-rates, for all purposes, viz., relief, medical relief, burial-grounds, registration of births, deaths, and marriages, sanitary measures, expenses under Superannuation Act, payments under Cattle Disease (Animals) Acts, and under National School Teachers Act, was, in 1880, £1,187,248, making a poundage of *ls.* 8*d.* on the valuation, the expenditure in 1881 for those purposes was £1,251,617, being an increase in the total expenditure of £64,369, and making a poundage of the expenditure on the valuation of *ls.* 9*d.*

The current sanitary expenditure for the year was £48,918, in comparison with £51,927 in the previous year.

THE UNION OFFICERS' SUPERANNUATION BILL.

A RESOLUTION passed by the Waterford Board of Guardians, protesting against the passing of this Bill, was adopted.

THE HEALTH OF DUBLIN.

ACCORDING to the monthly report by Dr. Cameron, Superintendent Medical Officer of Health for Dublin, the deaths within the Metropolitan Area during the five weeks ended 3rd June were in the ratio of 26.5 per 1,000.

The deaths within the City were in the annual ratio of 28.9.

On the northern side of the city the rate was 23.18; on the southern, 28.74.

The deaths from the seven principal zymotic diseases were, in the whole registration district, in the ratio of 2.52.

As compared with the first four months of the year, there was a considerable decline in the mortality caused by measles. There was no mortality caused by whooping-cough. Only one death was ascribed to scarlet fever, and two each to diphtheria and simple continued fever.

The following table shows the death-rate within the municipal districts of the metropolitan registration area since January, 1881:—

Death-rate per 1,000 persons from all causes—

1881.									
Jan.	Feb.	March.	April.	May.	June.	July.	Aug.	Sept.	
42.01	44.25	34.6	31.78	27.05	23.7	22.37	20.27	21.24	
Oct. Nov. Dec.									
22.62	27.68	37.75							
1882.									
Jan.	Feb.	March.	April.	May.					
39.75	39.14	36.97	33.	28.94					

The following figures show deaths from zymotic diseases and all causes in May, 1882:—From all causes, 28.94; measles, 29; scarlet fever, 1; typhus, 4; typhoid, 7; continued fever, 2; diarrhoea, 9; diphtheria, 2; total, 54.

State of Public Health in May, 1882.—The death-rate was, as already stated, 28.94, being an increase of 1.79 as compared with 1881, but a decrease of 7.93 as compared with 1880. With the exception of measles, none of the zymotic diseases caused much mortality. Not a single death was caused by whooping-cough, and scarlet fever and diphtheria caused only one death respectively. As compared with the previous month, there was a lessened mortality due to fevers, whilst there was an increase in the fatal cases of diarrhoea and dysentery.

The deaths within the Metropolitan Registration Area during June were in the ratio of 19.17 per 1,000.

The deaths within the City were in the annual ratio of 22.1.

The deaths from the seven principal zymotics were, in the whole district, 1.55 per 1,000 persons. In the city, 1.72 per 1,000 persons.

As compared with the preceding month, there was a

large increase in the fatal cases of diarrhoea and dysentery, a large decrease in the mortality caused by typhus, whilst, as in the previous month, the deaths from the other zymotic diseases were very few. There were only 2 deaths from measles as against 29 deaths from this disease in May, and a still larger number in the previous months of 1882. There was no mortality caused by diphtheria. Only one death was ascribed to simple continued fever.

STATEMENT OF CASES WHERE GUARDIANS REFUSED TO GRANT SUPERANNUATION ALLOWANCES, AND WHERE AMOUNT AWARDED WAS INSUFFICIENT.

(Concluded).

No. 63. *Dispensary Medical Officer*—This officer, who died about two years since, aged 75, clung to office, as Medical Officer of Dispensary, although incapacitated by extreme deafness, rheumatic gout, and great infirmity, and would not be allowed a penny pension.

No. 64. *Relieving Officer*—68 years of age, 31 years in the service. This officer asked Guardians, individually and privately, if he would be allowed superannuation if he resigned, and he was told, in every instance, that not one penny would be allowed him, so he holds office still, and will have to do so unless superannuation becomes compulsory.

No. 65. *Relieving Officer*—64 years of age, 27 years in the service. Would resign at once if entitled to superannuation as a right.

No. 66. *Clerk of Union*—This officer writes:—"I am over 60 years of age, and entered the service in 1844, but cannot yet afford to retire on superannuation, even could I claim it as a right."

No. 67. *Clerk of Union* writes:—"There is no officer in this Union over 60 years of age; I am myself the oldest and although I am 32 years in office, if I had to go out to-morrow, I do not believe that my Board of Guardians would give me one sixpence superannuation."

No. 68. *Clerk of Union*—67 years of age, 41 years in the service—writes:—"Age and infirmity would make resignation desirable. I am not able to dig, and to beg I am ashamed."

No. 69. *Workhouse Medical Officer*—78 years of age, 36 years in the service. "Dr. N., the late Medical Officer of this Workhouse, held that office from the formation of the Union to the day of his death in 1876. He continued to discharge his duties as best he could up to and including the day he died. Although he was 78 years of age, feeble and tottering, he often told me he would have retired many years before, if he was sure of getting a pension, but he thought he would be refused a pension by the Guardians after resignation, and so was forced to hold on to the duties of an important office, where many hundreds of sick poor were depending, not only on his skill, but also upon his mental and physical ability to use it."

MOUNTMELLICK BOARD.

THE UNION OFFICERS' SUPERANNUATION BILL.

THE Clerk read the following letter:—

"47 Rowan Road, Brook Green, London, W.,

"17th August, 1882.

"SIR,—I beg to acknowledge the receipt of your two letters of the 15th inst., enclosing copies of resolutions passed by your board respecting the Union Officers' Superannuation Bill, and the dissolution by the Local Government Board of guardians of Carrick-on-Suir Union, and to say that with regard to both, as much has been done as the opportunities of the session and the forms of procedure in the House permitted.

"I am, Sir, your obedient servant,

"ARTHUR O'CONNOR."

IRISH POOR-LAW INTELLIGENCE.

THE IRISH LOCAL GOVERNMENT BOARD AS A PROTECTOR OF ITS OFFICERS.

It is but a few days since the House of Commons was engaged in considering a Bill which proposed to rescue the officers of unions in Ireland from the grasp of a certain class of guardians who are willing to wring from them the last drop of hard service and throw them out to starve and die when no more value can be squeezed out of them. It was proposed by the amended form of this Bill that the power to do all this should be still left to the guardian taskmasters, but that the Irish Local Government Board should have a power to revise the decisions of the guardians, and order pensions or increase their amount as they thought fit.

We resisted with all vehemence—and will continue to resist with every influence in our power—the proposition to leave the grant of a pension optional with the guardians, although we were told that the medical officers would be quite safe in the hands of the Local Government Board, who would be their protectors, and see full justice done to them, no matter whether the guardians liked it or not. But we had not forgotten the many instances in which the “protectors” had allowed the guardians to act unjustly, and flinched from a contest on behalf of the victimised doctor. We recollected cases in which reductions of salary had been allowed, for no good cause—in one case because the doctor kept a bicycle; and we could not forget the numerous instances in which, where medical officers appealed to them to instruct the guardians that it was their duty to pay disputed fees for sanitary prosecutions or lunacy certificates, the Board not only declined to do so, but actually passed to the guardians the hint not to pay these legally-authorized fees until they were forced to do so.

Feeling, therefore, that, if it came to a contest with a board of guardians over a doctor's pension, it was pretty certain that the guardians would bully the Local Government Board into sanctioning any injustice, however great, we have always insisted that medical officers should have their pension, subject to no one's option, if they have performed their duty effectively, and for the requisite period.

A case of the gross and disgraceful sacrifice of an

inoffensive workhouse medical officer by a board of guardians, by and with the sanction of the Local Government Board, has come to our notice, which makes us thankful that we and the Irish Medical Association have stuck to this policy, and which seems to us to prove conclusively that no protection can be expected from the Local Government Board under such circumstances. The facts are these:—A workhouse medical officer, in the County Waterford, was unfortunate enough to have to perform his duty in connection with a virago of a nurse and a workhouse master of violent temper, both of whom were everlastingly engaged in an internecine war, for which they had been brought to the block more than once. Being grossly insulted by this nurse, in the presence of patients and workhouse officers, the surgeon retorted with some hot language, and the circumstances were reported at once to the guardians. A sworn inquiry was held, and, having read every word of the reported evidence, we have satisfied ourselves that not a tittle of evidence was produced justifying the dismissal, or even censure, of the medical officer, who was admitted by all witnesses to have done his duty, *sans reproche*, during the whole period of his service. But it also became evident that the wrangle between nurse and master had made business between them almost impossible. Unhappily, however, the doctor had enemies—political, religious, or perhaps, personal, on the board of guardians, and when the report of the inquiry came up for discussion, a majority were for simply reprimanding the nurse and master and for *dismissing the doctor*. In fact, the opportunity was seized to get rid of the medical officer on the pretence of his unsuitability, and plant in his office one of the popular politico-religious colour. But this proposal was so obviously indefensible that the Local Government Board found it necessary to remonstrate. They accordingly wrote to the guardians to say that if any of the officers deserved dismissal it certainly was not the doctor, and that, if he were to be sent off, the other officers should, in fairness, go also.

But the guardians were determined to oust the medical officer, and they called on him to resign. He appealed to the Local Government Board, but received from them the coldest reception, and neither sympathy nor support.

They, in fact, wrote to the guardians to say that if they liked they might call on the doctor to resign, and that unfortunate officer, seeing himself deserted by the department which should have sheltered him against oppression, and being fearful that a further contest with the guardians might cost him his dispensary appointment, felt it his interest to abandon his office as surgeon to the workhouse, which he did last week by the following letter to the clerk of the union:—

Sir,—As I have at last received a definite reply from the Local Government Board, I beg to resign the appointment of Medical Officer of the Lismore Workhouse, which I have held for the last fifteen years, and which now I am compelled to resign without a single serious fault not only never having been proved, but never having been even imputed to me.

I beg to protest in the strongest manner against the gross injustice which has been done me, and though I send in my resignation, I do so only under compulsion, and leave it to the conscience of each guardian who has had any part in the nefarious conspiracy against me to answer to his God for the injury done me and my children.

I am, Sir, yours truly,

There is more than one aspect of this transaction from which it is interesting to Poor-law medical officers in general; but it is the conduct of the Local Government Board which appears in the worst light. As to the guardians, they have done what we believe a large proportion of their fellows throughout Ireland would do to-morrow if they were allowed—get rid of an officer who did not suit them politically, religiously, or personally, and put in his place a friend or one recommended to them for his partisan opinions. This they might be expected to do without pity, without reason, and without the least sense of decency, and, altogether, there is nothing at all unusual in the action of these guardians towards their medical officer. The Local Government Board, however, had no accusation to make against the surgeon—they were, or ought to have been—unswayed by partisan bias; they knew him to be efficient in the discharge of his duty, and they themselves stated officially that they saw no reason why he should be removed while others far more to blame were retained.

We do not know how far they may have allowed whispering as to the surgeon's unpopularity with the guardians to influence them in throwing that officer to their tender mercies, but, if that consideration had any weight, we seize the occasion to protest that the Board would grossly misconceive its duty if it sacrificed an officer for such reason. One of the chief reasons for which the Local Government Board exists is to save a well-conducted officer from the venom of hostile guardians, and, if it yields up in this respect the authority which it possesses to forbid an iniquitous transaction of this sort, it ceases to be entitled to any confidence on the part of the medical profession. Are we to understand that for the future the will of the guardians is to be law, and that the Local Government Board exists only as a bureau to record the supreme decisions of the Poor-law

guardians? If it pretend to a higher function, we desire to know why it has not had the courage to give effect to its own declared judgment, and insist that the medical officer shall not be dealt with differently from the other officers accused?

We cannot but regret that the medical officer in this case took the step of resigning as he did, because we firmly believe that had he refused to do so neither the guardians nor the Local Government Board dare dismiss him. As for the guardians, they have no power greater than a temporary suspension of duty, without even suspension of salary unless the officer be eventually removed.

Any dismissal must be effected by virtue of a sealed order of the Local Government Board, and thus the whole legal and moral responsibility for the act reverts eventually to that Board. We repeat that we greatly regret that the medical officer in this case resigned, because we do not believe that the Local Government Board could have justified a dismissal of him before the weakest jury in Ireland. His perfect capacity and willingness to discharge his duty were unquestioned, and we cannot think that the Board could maintain in court their right to "deem unfit" for office an officer whose sole fault was that he was not on cordial terms with the guardians.

The whole affair is a warning to medical officers to put no trust in their official protectors; to be prepared to fight their own battles, and depend on the law and justice to set them right, and not to rest their hopes upon officials who have said, as Pontius Pilate said to the Jews, "Behold! having examined him before you, find no fault in this man touching those things whereof you accuse him. And the voices of the chief priests prevailed, and Pilate gave sentence that it should be as they required."

THE HEALTH OF IRELAND.

ACCORDING to the quarterly summary of the births and deaths in Dublin and fifteen principal urban districts in Ireland, the number of deaths registered in the Dublin district during the quarter ending July 1st amounted to an annual ratio of 26·7 in every 1,000 of the population. The average rated in the second quarter of the ten years 1872-81 was 27·4. The ratio north of the Liffey was 26·9, south of the river 29·9. The deaths registered in London was equal to an annual mortality of 19·4; in Glasgow 25·6; and in Edinburgh 20·4.

The number of deaths from zymotic diseases registered was 278, being 329 under the number for the preceding quarter, and 42 per cent. under the average of ten years. The deaths from these diseases are equal to 3·2 per 1,000 of the population. No deaths from small-pox have been registered in Dublin during the last thirteen months, nor have any cases of the disease been admitted to hospital during that period. One hundred and nineteen of the deaths registered during last quarter were caused by measles, being 313 under preceding quarter, but 71 over average. Scarlatina caused only 4 deaths, against 18 in the preceding quarter and 16 in the corresponding quarter of last year. Six deaths were caused by diphtheria, against 7 in the preceding quarter. Only 1 death resulted from whooping-cough, being 13 under preceding quarter, and 43 under average. Fever caused 63 deaths (19 typhus, 11 simple continued and ill-defined fever, and 33 typhoid),

being 3 over preceding quarter. During the first quarter of this year there were 126 cases of typhus admitted into Dublin hospitals; in the quarter now ended the number of admissions was 96. Among the remaining deaths from zymotic diseases are 32 from diarrhoea and 11 from erysipelas.

The death-rate was 24.5 for the sixteen principal town districts in Ireland, the respective rates for the several districts being as follow, ranging in order from the lowest to the highest:—Dundalk 17, Sligo 19, Lurgan 21, Queens-town 21, Galway 23, Limerick 23, Belfast 23, Cork 23, Wexford 23, Newry 23, Waterford 23, Drogheda 25, Dublin 26, Londonderry 26, Kilkenny 28, Clonmel 29.

The deaths from the principal zymotics in the sixteen districts were 2.3 per 1,000, the rates ranging from 0.3 in Dundalk to 4.5 in Queenstown, and 3.6 in Waterford; the 52 deaths from all causes registered in Queenstown comprising 5 from typhus, 1 from simple continued fever, 3 from enteric fever, and 2 from diarrhoea, and the 134 deaths from all causes registered in Waterford including 2 from small-pox, 15 from typhus, and 3 from diarrhoea.

CORRESPONDENCE.

CONSULTATION ETIQUETTE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was very much surprised to see a letter from Dr. Cronin, of Slane, in your issue of last week, referring to a point of professional etiquette, especially as both a written and verbal explanation had taken place between us; the latter in the presence of the gentleman of the house, who informed Dr. Cronin that if there was any mistake in the matter, it was owing to his inadvertence in not conveying Dr. Adrian's instructions to him, and he regretted that he was the cause of the misunderstanding. However, I do not wish to enter into a discussion of the details of the case, which I know would be distasteful to the family concerned. I will simply conclude by stating that I consider the fact of Dr. Cronin having met me in consultation on the evening of the 19th, the date of his letter, and again on the 22nd of August, is a full refutation of his statement that I had acted unprofessionally towards him.

Yours, &c.,

J. W. ADRIAN,
Medical Officer to the Drogheda
Union Hospitals.

IRISH POOR-LAW MEDICAL REFORMS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As Dr. Chapman, unofficially, it is true, has, through the columns of your paper, taken notice of a letter of mine which you recently published, I will ask your kind permission to make a few further remarks on the same subject. In the first place, Dr. Chapman must think me a very antiquated member of the medical profession if he is under the impression that I belonged to the Irish Medical Association forty-three years since. What I meant to convey in my last letter, when I said I was a member of the Association from its commencement was that I had belonged from its commencement to the Association formed by the amalgamation of the Irish Medical Association and the Poor-law Medical Officers' Association, which latter, as well as I can remember, was the title of that originated and principally managed by the late Dr. Thomas Maunsell some twelve or fourteen years since, and was the means of doing much for the advantage of the Poor-law Medical Service. Before that time I do not recollect having heard much of the Irish Medical Association. I hope this will explain my apparent ignorance to Dr. Chapman's satisfaction. I suppose

errors exist in the minds of most men, and certainly I am not free from such; but Dr. Chapman appears to have discovered one of the existence of which I was not aware. He says: "Dr. Leatham must have forgotten that a few years ago the Association sent to the hon. secretary of every dispensary committee in Ireland a circular, clearly and fully pointing out the abuses of the present system, and warning all persons authorised to issue tickets who did not properly exercise that privilege that they thereupon become liable to be sued by the medical officer for the amount of his fees." Now I perfectly recollect this circular, and I am aware that very few of the members of committees ever saw or heard of it, for the simple reason that their meetings are generally held irregularly, and seldom more than three or four members at the outside present. I would therefore beg again to repeat my suggestion—that some means be taken to bring under the notice of all the members of committees in Ireland the fact that the issuers of tickets for medical relief to persons not entitled to them are liable for payment of fees upon such tickets being cancelled; and I think this could easily be done by the Secretary of the Association sending to each dispensary medical officer a number of circulars proving this fact, which the medical officer should then send to each member of his committee. Dr. Chapman complains of my saying that the Irish Medical Association takes credit to itself for the passing of the Act for the Examination of Dangerous Lunatics, and says it does nothing of the sort, but what it takes credit for is the passing of a Bill allowing fees for such examinations. Dr. Chapman must know very well that this was the meaning of the remark in my letter, and I will now go further than I did in my last letter, and say that there are numbers of dispensary medical officers in Ireland who for years (and it is a matter for congratulation) never receive even one guinea for examining dangerous lunatics, so that I really cannot see what grounds the Association has for taking much credit to itself in this matter. Of course, in Dublin and other large towns it may be, and doubtless is, a source of considerable income, but not so in country districts. I am glad that any part of my letter should meet with the approval of Dr. Chapman, which it does when he says I paid a well-merited compliment to the successful efforts of the Association in the interests of Poor-law medical officers; and I agree with him that it is a shame that one-half the Poor-law medical officers never give the least support to the Association, but quietly pocket all the advantages they gain at the expense of the other half, and of a number of uninterested medical men in no way connected with the Poor-law Medical Service. I, for my part, gladly offer my best thanks to the official members of the Association, and particularly to Dr. Chapman, the Hon. Sec.—a more energetic and painstaking one there could not be. I know quite well that the Poor-law Medical Service is not an acknowledged branch of the Civil Service (though, if I mistake not, it was stated in the House of Commons last session to be such by a member of the Government, in a debate connected with the dismissal of a medical officer of the North Dublin Union), but when half our salaries are paid by the Government I think there are some grounds for trying to have it made so, and I would suggest that the Association keeps this object in view. I hope that Dr. Chapman will not think that I write with the object of finding fault with the Association; on the contrary, it is my wish, by every means in my power, to increase its influence—by doing so I know I would improve my own position and that of every medical man in the Poor-law service, and I trust that I may be the means of stimulating it to further exertions in our behalf.

I remain, your obedient servant,

W. LEATHAM.

Brackville, Coalisland.
6th Sept., 1882.

WESPORT UNION.

SANITARY FEES.

DR. JOHNSTON's bill for expenses, &c., incurred by his attending as witness for the board at last Assizes, in reference to the chargeability of a sewer was considered.

Local Government Board's letter produced. It stated that the Board had power to grant extra fees and expenses.

Chairman—Yes, but the Local Government has power to fix the amount, and they should have informed us what to do in the matter.

After a discussion as to whether Dr. Johnson was entitled to extra remuneration or no, he being literally acting in the discharge of his duty at the time, according to the opinions of some of the guardians, a minute to the following effect was entered:—

"The guardians decline to recommend any sum to be paid to Dr. Johnston for his attendance at Castlebar on sanitary duty. When he was appointed sanitary officer giving evidence in cases reported on by himself was part of his duty (guardians paying his expenses) for which he received his salary.

"Since then an Act has been passed, giving the Local Government Board power to oblige the guardians to pay their medical officers for these and many other duties (formerly part of their normal work). Under these circumstances, the guardians are prepared to obey the law, but nothing more, and will, in accordance with the law, pay whatever sum the Local Government Board decide upon.

"The guardians take this opportunity of impressing on the Local Government Board that the many extra fees recently made payable are a heavy charge on the ratepayers, and a great discouragement to the guardians in administering the sanitary and vaccination Acts."

[It would be very desirable that those who advise Boards of Guardians throughout Ireland would study some primer of the law of Union local government under which they act. If they did so they would learn that the guardians have nothing whatever to say to the amount of sanitary witness fees, nor can they in any way dispute payment. The Local Government Board has fixed the amount and the guardians must pay it, as the section of the Public Health Act (Ireland) gives them no option.—Ed.]

BALLINROBE UNION.

MR. MORRIS proposed that Dr. M'Guire's salary be increased from £100 to £130 a year. He said that from the amount of work Dr. M'Guire had to perform and the length of his district, with two dispensaries to attend to, it was necessary to increase his salary to enable him to keep a second horse. That was the opinion of the dispensary committee at a late meeting. From his own experience he could say that for some years back the doctor could not be able to discharge his duty but for the kindness of his neighbours in frequently lending him a horse.

Mr. Donnellon said when first spoken to about this matter he understood the increase would not exceed £20, and he gave his consent to that when in ignorance of the facts with respect to Dr. M'Guire and the others or he would not promise. There were four other medical men in the union, all most likely to go in for an increase of £30 if that sum is granted in this instance, and that would be voting away £150 of the money of the ratepayers of the union.

Mr. Moran—This is an exceptional case; no doctor in the union can put in such a claim for an increase. They have their dispensaries at their doors, while Dr. M'Guire has two dispensaries to attend, and situate several miles asunder. The increase would amount to one-eighth of a

penny on the ratepayers, and any person who has any experience of his valuable services and his great attention to every case will not complain.

Mr. Donnellon—Dr. M'Guire is there for many years, the circumstances the same. Why not this increase brought forward sooner?

Mr. Farragher said, together with Dr. M'Guire having two dispensaries to attend to, he had a very large district—about twenty-four miles by six miles, some parts so hilly that it is difficult to travel it—not chiefly farms, but a large population. And Dr. M'Guire is extremely kind and attentive to the wants of the people; he would remain in the dispensary if necessary up to six o'clock. It might be easy to get a medical man to take the situation at the present salary, but very difficult to get such a skilful, clever, and successful medical officer as Dr. M'Guire. He could mention cases where the sick were despaired of by others before Dr. M'Guire was called in that are now strong and in good health.

On a division, for the increase, 10; against, 1.

At a subsequent meeting of the guardians a letter was read from the Local Government Board, to the effect that they did not see any reason for the proposed increase in the salary of Dr. M'Guire, medical officer of Cong dispensary district.

Proposed by Mr. Farragher, seconded by Mr. Fitzpatrick, and adopted—

"In reply to the letter of the Local Government Board of the 3rd instant, declining to sanction an increase of thirty pounds per annum to the salary of Dr. M'Guire, of Cong dispensary district, the Ballinrobe Board of this date beg to submit the following grounds on which they and the Board of the 27th ultimo rest Dr. M'Guire's claims to the proposed increase:—

"In the first place, Dr. M'Guire having to attend two dispensaries seven miles apart, and having to answer sick calls, often involving a journey of twenty-eight miles, is obliged to keep two horses to enable him to discharge his dispensary duties efficiently.

"In the second place, emoluments from private practice are very little, from the fact of there being very few resident gentry and no town of importance in the district.

"In the third place, the doctor has spent ten years in Cong district, and the previous ten years in the adjoining district of Clonbur, during which long period he has given the greatest satisfaction to all concerned, and particularly to the poor.

"In the fourth place, the Committee of Management, with the full concurrence of the ratepayers of the district, unanimously recommended this increase at their meeting held at Cross on the 8th ultimo. At this meeting fourteen members, including three local magistrates and several heavy ratepayers, attended, all of whom were loud in their praises of the manner in which Dr. M'Guire has always discharged his onerous duties.

"In the fifth place, at a meeting of the Ballinrobe Board, held on the 27th ultimo, at which 13 guardians attended, eleven strongly recommended the proposed increase—one guardian alone dissenting, and one declining to vote.

"Finally, a very strong reason in favour of the increase will be found from comparing Dr. M'Guire's present salary of £100 a year with those of other doctors in some of the adjoining districts."

THE Editor of the *Irish Medical Directory* will feel greatly obliged if those gentlemen who have not yet returned their corrected statement of qualifications, &c., for insertion in the *Directory* for 1883 will do so at once. He also solicits information as to inaccuracies, either of omission or commission, in last year's issue, as, in consequence of the difficulty of eliciting replies, he finds it almost impossible to eliminate all errors.

IRISH POOR-LAW INTELLIGENCE.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

Mr. HENRY ROBINSON, Examined.

1. Chairman (Mr. Herbert Gladstone).—You are Vice-President of the Local Government Board in Ireland?—I am.

2. Will you tell the Committee how long you have held office?—I have held the office of Vice-President about three years and a half, and before that time I had been for about 28 years connected with the Poor-law administration as an inspector.

3. Will you describe to the Committee the existing state of the law with regard to the superannuation of poor-law officers in Ireland?—Up to the year 1865 a superannuation allowance could not be given to union officers; but at present there are three Acts of Parliament in force on the subject. The first Act, which was passed in the year 1865, enables boards of guardians, with the consent of the Local Government Board, to "grant to any officer whose whole time has been devoted to the service of the union, and who shall become incapable of discharging the duties of his office with efficiency by reason of permanent infirmity of mind or body, or of old age, upon his resigning or otherwise ceasing to hold his office, an annual allowance not exceeding in any case two-thirds of his then salary." That Act also provides that "no officer shall be entitled to such allowance on the ground of age, who shall not have completed the full age of 60 years, and shall not have served as a union officer for 20 years at the least." Then, in the year 1869, a further Act was passed, which extended the provisions of the previous Act to medical officers, although the whole time of the medical officers may not be devoted to the service of the union. And in 1872 a third Act was passed, which brought the superintendent registrar of births, deaths, and marriages, being the clerk of the union, and the registrar of births, deaths, and marriages, within the operation of the former Acts. It also enabled the officers to receive superannuation allowances upon their emoluments as well as their salaries. The result of this legislation is that any officer who has devoted his whole time to the services of the union, and any medical officer, whether he has devoted his whole time or not, may receive a superannuation allowance not exceeding two-thirds of his salary and emoluments. But, perhaps, it would be well that I should take this opportunity of mentioning to the Committee, with reference to the superannuation allowances that are granted to officers, that in consequence of the great diversities of practice which we found to exist amongst the boards of guardians with reference to the amount of allowances granted to the officers, and in consequence of finding that the superannuation allowances proposed were in some instances very disproportionate to the length of service, we found it necessary last year to issue a circular describing to

the boards of guardians the principles upon which we should be governed in consenting in future to grant superannuation allowances, and we were governed by the scale laid down in the Civil Service Superannuation Act; but at the same time we stated that officers having special or professional qualifications might receive a certain number of years in addition to their actual service; that is to say, a certain number of additional years might be counted. We thought that it was never intended by the Superannuation Acts that an officer should receive the maximum amount allowed by the Acts irrespective of his length of service; and we also thought it was clear that when the responsibility was placed upon the Local Government Board of consenting to a pension, it was not intended that we should merely act in a ministerial and perfunctory manner, but that we should exercise the control given to us by law for the protection of the ratepayers. Since that time we have sanctioned pensions in accordance with the Civil Service scale, allowing, as I mentioned, some extra years for professional and special qualifications. I may also mention that the same course was adopted in England by the Local Government Board with regard to the officers of their Board, and the same course was adopted in Ireland by the Lord Lieutenant with regard to the officers of the local authorities. So that the Poor-law officers in Ireland and in England, and also the officers of the local authorities in Ireland, are in the same position in that respect.

4. Since the issue of the circular all pensions which have been brought to the notice of the Local Government Board have been granted upon the scale you have mentioned?—Yes, all the pensions granted since the date of the Act. There were some pensions which had been granted before the issue of it, but the question had not then been decided. But in the case of any officer who resigned after the date of the circular, in dealing with his pension we were governed by the principles laid down in our circular, giving a very liberal number of years in addition in many cases. With the permission of the Committee, I will beg leave to hand in the English Circular, the Irish Circular, and the Circular of the Lord Lieutenant. (*The same were delivered in.*) I may observe that the purport of the English Circular is very nearly the same as that of the Irish Circular. The last clause, with regard to the refusal of the guardians to grant pensions, is in ours and not in the English Circular; but in other respects the principles laid down are precisely the same, and precisely the same as those in the Circular issued by the direction of the Lord Lieutenant.

5. What is the number of officers who have become superannuated?—The first Act, as I mentioned before, was passed in the year 1865, and from that time to the end of the last financial year, that is to say, to the 29th of September last, being a period of about sixteen years, there have been 662 officers granted superannuation allowances, and at the end of the last financial year there were 355 remaining in receipt of those allow-

ances; and the total cost of the pensions last year was £14,987, being about a farthing in the pound on the valuation of Ireland; and the expenditure in reference to new pensions granted during each of the three last years was as follows:—There were new pensions granted in 1879 to 45 officers, at a cost of £1,971; in the year ending September, 1880, there were 43 officers, to whom pensions were granted at a cost of £2,020; and in the year ending 1881 there were 55 officers pensioned at a cost of £2,335.

6. Is it your opinion that the existing Acts have worked well?—It is not my opinion. My opinion is that the operation of the existing law has been very unsatisfactory and unjust to the union officers, and prejudicial to the interests of the public service. I consider that it is unjust to the officers, because they have no security that they will ever receive superannuation allowances on retiring from the service. There are many instances, indeed, in which pensions have been refused, and in which very great hardship has been inflicted in consequence upon the union officers. There was a return called for in the year 1880 of the medical officers who have retired since the passing of this Act—Mr. Meldon's Return; and this year there was a similar Return prepared and laid upon the table of the House with regard to all the other officers, exclusive of medical officers; and in looking through those Returns, there are some very striking cases, indeed, of hardship. I will mention two or three, if the Committee wish, but I believe that witnesses will come after me on behalf of the union officers, who will, perhaps, give more full information upon the subject. But I may mention two or three cases which struck me very forcibly. Taking one union, there was a fever hospital nurse, who was 70 years of age, and she had served over 24 years—nearly 25—and she was refused a pension on retiring.

7. Mr. Meldon. Where shall we find that?—These are a few of the cases extracted from your Return, and from the Return of the union officers who have been retired since 1865.

8. Amongst which Returns will that be?—In the Cavan Union.

9. Chairman. Was any reason given for refusing a pension in that case?—The clerk of the union in furnishing the Return stated that the objection of the guardians was an objection on principle to granting any person in future a pension.

10. Did he state what that principle was?—No. I can only read the observations of the clerk on that case.

11. Mr. Healy. Under this scale what would this lady have been entitled to after 24 years' service?—Under the Bill she would be entitled to 24 60ths of her salary; but I have not got a statement of the salary here.

12. Chairman. What would she be entitled to under the Civil Service Act?—She would be entitled to 24 60ths of her salary and emoluments, which form a very considerable item of what is paid to resident officers. I have another case in which a nurse 70 years of age, and with 22 years of service, resigned from bodily infirmity, and she was refused a pension, and the clerk says that it was considered that she ought to have saved money out of her salary, which I find was only £12 a year.

13. Mr. Daly.—In what union was that?—That was in the Ballymena Union.

14. Mr. Healy.—Could you give us any idea what addition to the £12 a year her emoluments would have been?—They would be a great deal more than her salary. I should think that her rations would probably be valued at about £18 or £20 a year, and she would be allowed also something in respect of her other emoluments; for instance, the value of her apartments, and light, and fire, and I should say that between £20 and £26 a year would be the value on the average of an officer's rations.

15. Altogether she would be in receipt of £40 a year.—I should say probably about £35 a year.

16. Mr. Biggar.—And she would be entitled to two-fifths of that?—A little more than a third. I have another case, in which the master of a workhouse who had served for 24 years, and was 67 years of age, resigned from bodily infirmity at that age, and he was refused a pension and no reason given. Another officer in Donegal, 68 years of age, with 16 years of service, who retired from ill-health, was also refused.

17. In what union was that?—The first of these two cases was in Cootehill, the second in Donegal.

18. Chairman.—Is it not the case that a union officer has to resign one month before the question of a pension would be considered by the board of guardians?—The guardians must give a month's notice of their intention to grant a pension, and that notice cannot be given until the officer has actually resigned.

19. Mr. Daly.—What was the age of the person that you last adduced who had 16 years' service?—Sixty-eight years of age; and in that case there was a division in the board of guardians about refusing; the guardians were equally divided, and they gave no reason for it. Consequently, there being an equal division, the motion was lost, and the officer received nothing.

20. Chairman.—When an officer resigns he has no notion, I presume, whether he will be granted a pension or not?—I think he has a pretty good notion, but he has no certainty whether he will get it or not.

21. Mr. Callan.—Is it through the default of the guardians, or through the default of the Act that he has no assurance?—Under the Act the guardians cannot pass the resolution until after he has resigned.

22. Therefore it is not through the default of the guardians, it is through the default of the Act?—I do not exactly understand what you mean by saying through the default of the Act. The Act does not enable the guardians to pass a resolution on the subject until more than a month after the man resigns; and unless he has got private information as to which way the guardians will vote, he is in a state of uncertainty.

23. Therefore if any injury accrues to the officer from the circumstances, it is through the Act, and not through the default of the guardians?—Certainly. I have another bad case here, that of a fever hospital nurse, 78 years of age, with 28 years' service; and the reason given by the clerk for the guardians refusing her a pension was that they were totally opposed to superannuation allowances.

24. Mr. Solicitor-General for Ireland.—As a matter of fact, is it necessary that the officer should resign a month before he knows whether he will get any pension or not?—At least a month before, because notice cannot be given until he has resigned, and then it takes a full month before the guardians can consider the subject.

25. Mr. Biggar.—In what union did this case of the hospital nurse occur?—In the Enniscorthy Union.

26. Mr. Daly.—Are you aware whether in the case of any of those officers when they undertook the duties there was agreement with the Board that they should not apply for a superannuation allowance?—No, I have never heard of an instance of that sort.

27. I know of my own knowledge that in a similar situation a person accepted it who was over 45 years of age, and that the appointment is sometimes accompanied with that provision?—I have never heard of a case of that sort, and were that arrangement made it would be inoperative, because one board of guardians cannot control the action of a future board; and if one board of guardians entered into such an agreement with an officer, a future board would not be bound to abide by it.

28. Mr. Solicitor-General for Ireland.—Has any reason ever been alleged by such boards, for the refusal, that there was such a contract?—I have never heard of it. I have a case before me of the clerk of a union who was 38 years in the service, and he was 68 years of age. He resigned, and was allowed nothing, and there was no reason given for it.

29. Mr. Callan.—Where was that?—That was at Newtown Ards. I have another case of a fever hospital nurse, 68 years of age, in the Thomas Town Union, and with 25 years of service, and no reasons there have been given. These are a few of the cases which I have extracted, but the Returns are full of similar cases, and I believe that the representatives of the union officers will probably be able to give the Committee much more striking cases than I have done. I merely give these as a few to show the reasons which make me consider that the union officers have been very hardly dealt with in many cases.

30. Mr. Meldon.—Do you happen to know of any instances in which boards of guardians have acted rather too liberally?—Yes, several instances; and that was what caused us to issue our circular in November, 1881.

31. Could you refer us to any particular instances in those returns which unfortunately have not been printed as yet?—I could do so.

32. Chairman.—In your opinion, I suppose a large number of the present union officers are inefficient, owing to age and infirmity?—I would not go so far as to say a large proportion. I believe there are a great number, but those cases do not come officially before us. Unless an officer is removed for some neglect of duty no cases come before us; but an officer may be of an age that he cannot perform his duties very efficiently, and still he may not be actually reported.

33. He would probably have to employ a substitute in many cases?—No, I do not think that would be allowed, excepting as a temporary measure.

34. Mr. Daly.—Did I understand you to say that the reason for the issue of the circular of 1881 was that superannuation allowances had been awarded to officers more than the Local Government Board approved of?—It was the practice for some years after the Act passed to allow the guardians to do very much as they pleased, and then it was found that they exceeded what we thought right and reasonable, and moreover, there was such a diversity of practice, and the amounts given were so very disproportionate, that on those grounds we were influenced to issue the circular.

35. Were they the sole grounds?—The sole grounds.

36. Chairman.—With regard to those union officers who appear to have reached a considerable age, I suppose they do not resign because they are afraid that pensions will not be granted them?—There were some very striking cases mentioned by the members of a deputation who attended before the Chief Secretary last year—cases in which officers had remained in office when they were quite unfit to discharge their duties with activity and efficiently; but, as I stated before, those cases do not come before us, except in very rare instances. I think you will probably get those cases repeated by some of the members who were on the deputation to the Chief Secretary. Mr. Meldon asked me about officers who had been granted very large sums. The returns published in our Annual Report show numerous cases in which officers were granted the full amount which could be awarded them, although their service was very short. For instance, I have a case here in which an assistant clerk, who had only nine years' service, and was in receipt of a salary of £90 a year, and the guardians gave him the full two-thirds of his salary; they gave him £60 a year. That is to be found in our Annual Report, in the return of officers, but I find that he is dead now.

37. Mr. Solicitor-General for Ireland.—What was the age of that officer?—He was 55 years of age.

38. Mr. Biggar.—What union was that in?—That was in the North Dublin Union.

39. Mr. Callan.—Were there exceptional circumstances attending his case?—I am not aware of any. As I said before, it was our usual practice at that time to allow the guardians very much to exercise their own discretion, and not to interfere, because no distinct rule had been laid down about it; and, in fact, it was not until a circular was issued in which we notified to the guardians what

the principles would be that would govern us that we interfered very much.

40. Mr. Daly.—With regard to the person who was superannuated at 55 years of age, after nine years' service, and got £60 a year, were there any circumstances peculiar to his case which induced the guardians to accept his retirement at 55 years of age, and grant him two-thirds of his salary?—He was obliged to retire, from infirmity of body; he was unable to discharge the duties of his employment as assistant clerk. I do not know of any exceptional circumstances which would make it right that he should have had two-thirds of his salary. I have another case, in which an infirm nurse, with less than ten years' service, and the whole of whose salary and rations amounted to £37 10s., and she got £15 a year; she was 62 years of age. I have another case, in which an officer, the apothecary of the Drogheda Union, was under 61 years of age; he had served for ten years; his emoluments were £75, and he got £50 a year.

41. Mr. Healy.—In the case of those excessive pensions, is there anything to show how long the recipients of the pensions lived?—This pension to the assistant clerk of the North Dublin Union was granted in April, 1873, and he died in February, 1877. This infirm nurse whom I mentioned I think is alive still. The apothecary in the Drogheda Union was given a pension in 1874, and he died the next year, so that he probably was very ill at the time. I find in another case the clerk of another union, after twenty years' service, got two-thirds of his salary of £100 a year. There are numerous cases of that sort, which I mention just to show what induced us to think it necessary to exercise the discretion which is vested in us by the law.

42. Chairman.—Have you anything further to say with regard to the working of the Acts?—I mentioned that I thought that the present system was injurious to the public service, and my reason for expressing that opinion is just what you have alluded to in one of your former questions, that many officers, long after they are unable to discharge their duties efficiently, are induced to remain in the service, because they do not believe that they will be able to receive a pension, or at all events, will not be certain of a pension when they retire.

43. Mr. Findlater.—Then I suppose it would be necessary before a man gave notice of retirement, that he should sound the guardians to see what their tone of feeling was towards him.—Certainly, that is the case; and the officers can only know from private information that they can obtain as to how the guardians will vote, and from their knowledge of the guardians, and of the disposition of the guardians towards each officer; I think that is placing officers in a very unsatisfactory and degrading position.

44. Mr. Solicitor-General for Ireland.—Are you aware whether there is any fixed rule laid down by any board of guardians in this matter for themselves; do any board of guardians act upon a regular system?—No, they cannot make any fixed rule, for the reason that I mentioned before, that one board of guardians could not in such a matter influence the actions of a future board; but they may have an understanding among themselves, which, of course, I am unable to express an opinion upon, but from the fact that some unions have never given any pensions, and have always refused them, there can be no doubt whatever that the guardians of those unions have arrived at some decision and understanding amongst themselves that they will not grant pensions.

45. How many unions do you know in which you would infer that such an understanding exists from their practice?—That is a question which it is very difficult to answer. There are several unions in which they are not giving pensions, and have refused to give pensions, who at one time did give them, and they have refused since in some cases. I find that there are about ten unions in Ireland that never gave any pensions. Those at Bantry, Carrickmacross, Castleblaney, Donegal, Irishowen, Killa-

dysent, Mount Bellew, Portumna, Roscrea, and Wexford. I believe that to be a correct return. It does not appear that in all those cases pensions were actually refused.

(To be continued.)

LIST OF ENTRIES IN THE REGISTER OF THE
BRANCH MEDICAL COUNCIL (IRELAND) FOR THE
MONTHS OF AUGUST AND SEPTEMBER, 1882.

- AUGUST 2nd.—Sagrus, J.; Walsall; M.D. Q. Univ. Irel. 1881, M.Ch. R. Univ. Irel. 1881, Lic. Mid. K. Q. Coll. Phys. Irel. 1881.
- 2nd.—Yaw, M. T.; Dublin; Lic. R. Coll. Surg. Irel. 1882, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
- 3rd.—Dean, G. F.; Dublin; M.B. & B.Ch. Univ. Dub. 1882.
- 3rd.—Nason, C. St. S. R.; Rathcormac; M.B. Univ. Dub. 1882.
- 5th.—Heatly, R. J.; Dalkey; Lic. R. Coll. Surg. Irel. 1882, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
- 5th.—Evans, F. C.; Ballynahinch; Lic. R. Coll. Surg. Irel. 1882.
- 5th.—Thompson, W. C.; Dalkey; Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882, Lic. R. Coll. Surg. Irel. 1882.
- 5th.—Coall, R. H.; Kingstown; Lic. R. Coll. Surg. Irel. 1882.
- 8th.—Gemming, J.; Lettermore; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.
- 9th.—Lithgow, J. M.; Downpatrick; M.D. R. Univ. Irel. 1882.
- 9th.—Garland, J. P.; Dublin; Lic. R. Coll. Surg. Irel. 1882.
- 11th.—Taylor, J. W.; Belfast; M.D. R. Univ. Irel. 1882, M.Ch. R. Univ. Irel. 1882.
- 11th.—Jones, W. P.; Mohill; Lic. R. Coll. Surg. Irel. 1880, Lic. K. Q. Coll. Phys. Irel. 1881, Lic. Mid. K. Q. Coll. Phys. Irel. 1881.
- 12th.—Phillips, J. M.; Plymouth; M.D. R. Univ. Irel. 1882, Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.
- 16th.—Duncan, J. W.; Malin, co. Donegal; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.
- 16th.—Wynne, E.; Rathmines; Lic. R. Coll. Surg. Irel. 1882.
- 17th.—Wills, S. R.; Rathkeale; Lic. R. Coll. Surg. Irel. 1882.
- 18th.—Daly, T.; Monasterevan; Lic. R. Coll. Surg. Irel. 1881, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
- 19th.—Dutch, M. A.; Rathgar; Lic. R. Coll. Surg. Irel. 1882.
- 23rd.—Dunlop, P.; Lisburn; Lic. R. Coll. Phys. Edin. 1881, Lic. R. Coll. Surg. Edin. 1881.
- 24th.—McNaught, F. J.; Rathmines; Lic. R. Surg. Irel. 1882.
- 25th.—Irwin, J. K.; Loughgilly, co. Armagh; L.A.H. Dub. 1882.
- 25th.—McGee, W.; Donnybrook; Lic. R. Coll. Surg. Irel. 1882.
- 28th.—King, J. C.; Roundstone, Galway; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.
- 30th.—Power, J. S.; Waterford; Lic. R. Coll. Surg. Irel. 1882.
- 30th.—Graham, J.; Cookstown, co. Tyrone; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.
- SEPTEMBER 9.—Tanner, L. J. N.; Lapp's Ireland, Cork; Lic. R. Coll. Phys. Edin. 1878, Lic. R. Coll. Surg. Edin. 1878.
- 11th.—Williams, J. W.; Dungarvan; M.D. R. Univ. Irel. 1882, M.Ch. R. Univ. Irel. 1882.
- 12th.—Hennessey, T. J.; Ballylanders, co. Limerick; Lic. R. Coll. Surg. Irel. 1880, Lic. K. Q. Coll. Phys. Irel. 1882.
- 12th.—Harper, A. F.; 4 Grosvenor Place, Rathmines; Lic. R. Coll. Surg. Irel. 1882, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.
- 14th.—Devlin, T. P.; Ulster Villas, Belfast; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.

16th.—Kenna, D. P.; 55 Stephen's Green, E. Dublin; Lic. R. Coll. Surg. Irel. 1880.

20th.—Watson, J.; Hollywood, co. Down; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.

22nd.—Hutchinson, M. M. L.; New Ross; Lic. R. Coll. Surg. Irel. 1881, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.

23rd.—Pigot, E. F.; 12 Leeson Park, Dublin; M.B. Univ. Dub. 1882, B.Ch. Univ. Dub. 1882.

26th.—Loughheed, W. H.; Dromore, co. Sligo; M.B. and B.Ch. Univ. Dub. 1882.

27th.—Nicolls, J. P.; Navan; Lic. R. Coll. Surg. Irel. 1880, Lic. K. Q. Coll. Phys. Irel. 1882, Lic. Mid. K. Q. Coll. Phys. Irel. 1882.

30th.—Todd, A. T.; Finvoy, co. Antrim; Lic. R. Coll. Phys. Edin. 1882, Lic. R. Coll. Surg. Edin. 1882.

CAVAN UNION.

KILNALECK DISPENSARY.

Letter read.

"At a meeting of the Kilnaleck Dispensary Committee it was moved and carried that George Lyndon, Esq., M.D., be appointed for one month, as substitute to Dr. Alcock, who is at present unable to discharge his duty, as he is suffering from an attack of sickness caught in the discharge of his duty."

Mr. Lee said the Committee should have something to say in the matter of payment.

Mr. John A. Faris said Dr. Alcock often attended the Dispensary when he was not able to be there. He begged to move the appointment of Dr. Lyndon as his substitute.

Mr. Lee considered that Dr. Lyndon should not be paid more than the present doctor.

The Clerk—I will take care of that.

Mr. McCann thought Dr. Alcock *should be called on to resign*; he was a very old man, and moved that Dr. Alcock pay his substitute.

Mr. J. A. Faris considered that would be time enough when it would come from the Committee.

The Clerk said he (Dr. Alcock) got an attack of blood-poisoning in a midwifery case.

Mr. Nesbitt—Well, in that case, I move that the Board pay Dr. Lyndon.

Communication sent back to the Committee, to know who will pay the substitute.

[This Mr. McCann is the generous and kind-hearted person who was brought over by Mr. Biggar, M.P., to testify before the Select Committee of the House of Commons on Superannuation, that he "objected to the grant of a pension under any conceivable circumstances; that if the officer was too old or infirm to do his duty, he ought to be called on to resign; and if he and his family died of starvation or went into the workhouse to escape that fate, that was no business of the guardians." To do this person justice, he is an admirable representative of the Cavan guardians, who are notorious throughout Ireland for having worried more than one of their officers to death by the slow torture of starvation. Heaven be thanked there are not a great many of Mr. McCann's class to be met with, and that the law is such that Dr. Alcock need not care "two rows of pins" for them.—ED.]

AN inquest has been held at Keighley, Yorks, into the circumstances attending the death of a man named Riley, who was supposed to have died from lead-poisoning, caused by using the town's water. The West Riding analyst gave evidence as to the amount of lead absorbed by the water, which was so great as to be dangerous for domestic use. Dr. Meymott Tidy asserted that the deceased had not died from lead-poisoning, but from kidney disease. The jury returned a verdict to the effect that the deceased had died from lead-poisoning.

IRISH POOR-LAW INTELLIGENCE.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT
COMMITTEE OF THE HOUSE OF COMMONS, 10TH
AUGUST, 1882.

(Continued).

Mr. HENRY ROBINSON's examination continued.

46. Mr. Callan. Previous to your present appointment you were inspector in the district of Carrickmacross and Castleblaney?—Yes.

47. In the union of Carrickmacross and Castleblaney, in County Monaghan, and in any of the ten unions in Ireland which have never granted any superannuation allowances, in your opinion have any cases of alleged injustice been brought forward?—I remember, in the Carrickmacross Union, the guardians refused a pension to a medical officer about 65 years of age and 18 years' service. I have no returns from Carrickmacross with reference to any other officer.

48. Have you any cases of injustice in Castleblaney?—In the Castleblaney Union I find that the guardians, in the case of a fever hospital nurse, 65 years of age and 17 years service, who retired from physical and mental weakness, refused to give her a pension, and I will read you a note upon the case by the clerk of the union. He said, "This woman was afterwards in abject poverty, and applied several times for out-door relief, which was refused. It was, however, very well known that the refusal in this case arose from an unwillingness to give a precedent to other officers who had very long service, but who were, of course, to be refused also for the usual reasons given in such cases."

49. May I ask you, from your knowledge of the Castleblaney Union, is it not one of those unions in which the number of attending guardians are predominantly *ex officio* guardians?—I cannot say that now. I can put in a return of the attendance if the Committee wish it of the guardians of that union.

50. Chairman. You are, of course, acquainted with the provisions of the Bill which we are now considering?—Yes, I am very well acquainted with them.

51. Is it your opinion that it will be an improvement upon the present state of things?—I think that it will. I am very strongly indeed in favour of the provisions of the Bill. I think that it will be a very great improvement in reference to the administration of the Poor law in Ireland and the Medical Charities Act, if the Bill should be passed.

52. Can you give the Committee any estimate of the probable cost that will be entailed by the proposed changes?—I think that the cost will be somewhere about the same as it is at present. The pensions may be lower in some cases, but the number will probably at first be larger than the annual average at present. The cost, I see, last year, was £2,335. Those are the new pensions, and they only came to a fraction, 1-32nd of a penny in the pound in the valuation.

53. Mr. Healy. Do you really think that the amount of pensions will be lower?—Certainly, because they will be governed by the Civil Service scale.

54. Is it not the fact that taking the return, you show that there were certain pensions of £65 and £70 a year, but can you state what the average pensions have been all round granted to the medical officers and other officers?—I cannot distinguish medical officers from other officers, but I can state that the average pensions are about £42 or £43 a year.

55. I make it out that the appendix to the report of the Local Government Board of last year, at page 185, that from 1865 down to the 29th of September, 1880, there were 101 doctors receiving pensions?—That return is only a return of the officers who received pensions during that year. It is headed "Union Officers' Superannuation," in continuation of the statements in the previous report. This is a statement of allowances in force during any portion of the year, and it is merely a statement of the persons who received payments during that year.

56. From these returns I find that from the 26th of May, 1865, down to the 29th of September, 1880, there were 101 doctors pensioned, getting a gross pension of £6,830, which is an average of £68, and that there were 264 other officers of all kinds, receiving a gross amount of £6,824, or an average of £26 each?—That very much corresponds with my statement that there were only 355 officers altogether.

57. You have stated that the average amount would be about £43 or £45, but I make a distinction between the doctors and those other officers, because if it be true, as you state, that the other officers' pensions would be generally lower, and as a matter of fact the average for the other officers has only been £26, distinguishing the other officers from the doctors, and where the doctors get £68, I can hardly see how you can make out that a less pension than £26 would be more favourable than the present pension?—I do not take any class of officers separately. I take the whole list of officers; it is only a surmise, for it is impossible to form an accurate opinion upon the subject. I think, as a general rule, the amount in individual cases would be less, because there are so many instances in which an officer has received a great deal higher amount than the Civil Service scale.

58. Mr. Solicitor-General for Ireland. Your inference would be that although in individual cases the pension might be less than it now is, it would be more widely distributed?—I think that there would probably be more officers in the first year or two put on pensions than there have been on the average of the last three or four years, because there are those officers who have remained in office from a fear of not getting pensions if they resigned and who will probably now get the advantage of a pension.

59. Mr. Healy. As I understand, you refer to the general effect on the whole body of officers, and not to cases of individuals?—Yes; I refer to the whole body of

officers, but it is very difficult to express a decided opinion as to what the cost would be. The first rate to be struck must be a rate for 18 months, because we should have to pay a portion of the first rate for pensions to be paid from the time of the passing of the Act up to December, 1883, whereas afterwards the rates will only be for the amount required for each year.

60. Mr. Findlater. Do I understand the tendency of your evidence to be that by adopting the Civil Service scale in Ireland greater justice would be done?—Unquestionably, that is my decided opinion.

61. Chairman. And you think that there would be no difficulty on the part of the union on the score of expense?—Not the slightest difficulty. We shall ascertain the amount that will be required, and make an assessment upon each union according to the net annual value of each union, and we shall send an order to the treasurers of the union to lodge it in the general fund, which will be in our hands in the bank, and twice a year we shall recoup the boards of guardians the amount that they have paid in pensions.

62. Mr. Daly. If I understand you, when you assess the amount to be disbursed under the head of the superannuation fund, it will simply be by the Board imposing on each locality the superannuation allowance in respect of the officers, or will it be a general rate for the unions in Ireland?—It will be a general rate all over Ireland, according to the net annual value of each union.

63. Irrespective of the superannuation allowances in a small or a large union?—Yes, certainly; they would be paid out of one general fund.

64. You tell us of boards of guardians who make more liberal superannuation allowances than those sanctioned by the Local Government Board, and, as a contrast, you mention another union that makes smaller superannuation allowances than those sanctioned by the Local Government Board; then the union granting the smaller allowances will pay its quota to the one with the larger superannuation allowances?—The Act provides that if any officer is dissatisfied at not receiving the amount that may be awarded under the Civil Service scale he may appeal to us; and therefore, I think it may be concluded that in the case of every officer who is efficient and against whom there is no fault, he will be awarded by the guardians, or given by us, the full amount that he will be entitled to by the scale. Therefore, I think that all the officers, unless there is a fault on their parts, will be pensioned on the same scale.

67. In fact the manner in which money is raised under that Act is a kind of rate in aid?—It is a rate all over the country. It is a general rate.

68. Mr. Solicitor-General for Ireland. So that there would not be under this Bill the same inducements to the poorer unions to refuse superannuation allowances?—Certainly not.

69. Mr. Findlater. Would you not equally increase the allowances under the powers of the Bill, if they were not liberal enough?—The Act, as amended, provides that if an officer is dissatisfied with the decision of the board of guardians, or if the board of guardians give a lower amount than that prescribed by the Civil Service scale, there may be an appeal to us, and we may decide the case.

70. So that there would be no object in guardians being less liberal?—No. If a board of guardians have reason to be dissatisfied with the conduct of an officer, and an appeal is made to us, the board of guardians will have full power to attend that appeal and give their reasons for what they have done, and it will be for us to decide whether those reasons are sufficient or not.

71. Captain Aylmer. Am I to understand that the initiative in granting those pensions or superannuation allowances is to be with the boards of guardians under the proposed Act?—As the Bill was drafted, the Local Government Board were to determine the amount of the pension; but that is proposed to be amended by a new clause to be added to the Bill.

72. Mr. Solicitor-General for Ireland. Do you anticipate that under this Bill there will be practically uniformity throughout the entire of the unions of Ireland?—There will be a uniform rate to form the fund, but the amount to be given to each union will be according to the amount of superannuation allowance awarded to the officers of that union.

73. Do you anticipate that there will be a practical uniformity of principle as regards pensions?—Yes, certainly there will be a practical uniformity of principle and of practice. I may mention that one great object in establishing this national rate, a rate all over the country, instead of levying a rate in each union, is that there is a difficulty with respect to the officers moving about from one union to another. If we had not a rate over the whole country there would be a difficulty in charging one union with the pension of an officer, and allowing him to take credit for his serving another union; whereas by this method it is as broad as it is long; officers will be allowed to count their service in whatever unions they may have passed their time, in a case where an officer was changed from one union to another.

74. Mr. Callan. You do not mean that to apply to the case of officers changing from one district of a union to another?—No, that would not apply. Pensions are now all charged to the union at large; I think it is only as between one union and another union.

75. Mr. Solicitor-General for Ireland. You mean to meet the cases of officers who have served a considerable time in one union and then have gone to another?—Yes; there are many such cases, and it is often of great advantage that an officer who has gained experience in a small union should, when occasion arises, be transferred to a large and important union, which would thereby get the advantage of his great knowledge and experience.

76. On what scale would his pension be calculated?—At present there is no scale. The guardians give what they see fit, but we cannot fix a scale of that kind, and say that an officer should be pensioned according to it the year after, and place the whole of that charge upon one union, whereas, he may have served the greater part of his time in another.

77. Mr. Daly. Then the effect of that, as I understand, will be that wealthy unions will contribute towards the superannuation funds in a larger proportion by reason of their greater wealth than smaller ones?—They will.

78. And their disbursements will go out from that fund, and not be lessened or made greater by reason of any particular superannuation allowance in that locality?—We must bear this in mind, that a very large and wealthy union would have a staff of officers so very much larger than the number of officers in a poor union, that the superannuation allowances would be much larger than those of a small and poor union. Take the difference between the Dublin Union and the Union of Skull, in the County of Cork; although the amount may be very much larger than the guardians of the Dublin Union would have to pay, still the number of their officers would necessitate a much greater number of retirements.

79. Mr. Healy. Is not the shifting of officers from one union to another one reason for introducing the change?—I think that it would facilitate the whole arrangement. That is one reason, and I think in every respect it is better.

80. Would you state your reasons?—That is the principal reason; but I think there would be an objection probably made to an appeal to us in dealing with the funds of one particular union. It was at first intended, when the Bill was drafted, that we should fix the pensions ourselves without reference to boards of guardians, but we felt that the boards of guardians would probably object much more to our fixing the sums if we interfered solely with the rates of their own union, but there would not be the same feeling if it were the national rates that we were dealing with, or, a rate all over the country.

85. Mr. Callan. I suppose that you were consulted about this Bill?—I was.

86. Have you read the amended Act proposed by some of the union officers, and by the Irish Medical Association, and by the Poor-law Officers' Association of Ireland?—I have read the amendments proposed to this Act.

87. Are you still of opinion that the Act as originally introduced is in the best form?—I think that it would save trouble; but I do not in the least object to the other.

88. Save trouble to whom?—Perhaps I should rather have said that it would save correspondence.

89. You mean correspondence on the part of the Local Government Board?—Yes.

90. Is that the principal recommendation for retaining the Act in its original form?—But I do not advocate retaining it in its original form; I am quite satisfied with the amendment.

91. Do you prefer the amendment to the original?—I do not prefer it; I think that the original Bill would save correspondence, and perhaps a difference of opinion between us and the boards of guardians.

92. Discarding all idea of trouble to well-paid officials, do you think the proposed amendment an advantage?—I do not say that it is an advantage, but I say that I have no objection to the alteration.

93. Have you read the reasons why those amendments should be proposed?—I have read them.

94. Will you just take the Bill in its present shape before you, and look at page 1, line 17; is it a fact that the words are "not exceeding ten-sixtieths"?—Yes.

95. Is it the fact that the words "not exceeding" are without precedent?—No.

96. You have gone now on the lines of the Civil Service Act of 1859?—Yes.

97. There the words "not exceeding" are not found in the same sentence as they are here?—I do not find the words "not exceeding" in the Civil Service Superannuation Act.

98. Is not the word "of" used?—The words are "to any person who shall have served 10 years and upwards and under 11 years, an annual allowance of ten-sixtieths of the annual salary and emoluments of his office."

99. Can you give me any reason why, as you admit that you drafted these clauses from the Civil Service Act of 1859, you should have expunged the word "of" in that Act, and inserted instead the words "not exceeding"?—Yes, I can. I think it is desirable that the guardians should have in some cases, and certainly that we should have in some cases, power to grant a reduced pension if necessary. Subject to our approval, the guardians have the power under the Act as it stands, to give a reduced pension, and a union officer might appeal to us, and we should then hear the views and reasons of the guardians for asking to give a reduced pension.

100. Would not that be still more open to your principal objection; would not it give a little more correspondence, and a little more trouble to the Local Government Board?—Whether it originates with the Board of guardians or originates with us these words will make no difference. At present cases arise, and have arisen, in which we have not approved of the vote, and we have reduced the pension. Circumstances may arise in which an officer had for a great number of years performed his duty in a very efficient and satisfactory manner (I have a case in my mind now of that sort), but his health failed, and in consequence of ill-health for the last few years of his service he performed his duty in a very inefficient and unsatisfactory manner; and he was at last compelled to leave the service; and, in sanctioning a pension to him, we thought it was not right to deprive him entirely of his pension in consequence of what occurred during the last few years, his negligence and inefficiency having arisen from the state of his health, and we allowed a pension to be awarded him in that case, computed on the number of years' service in which he had served efficiently.

101. Did you lower the allowance?—Yes.

102. By how much?—We allowed him to count his pension upon his efficient years' service, solely because we

thought that his inefficiency during the last few years was caused by failure of energy and loss of sight.

103. Did the guardians remonstrate on that occasion? Yes, I rather think they did.

104. And therefore, the Local Government Board overruled the decision of the guardians, the local parties, who paid the superannuation allowance? Certainly; we have done so in many cases where they have awarded pensions in excess of the scale.

105. With regard to the Circular of November 1881, I see that you issued it when the guardians exceeded what you thought right and reasonable? Yes.

106. Did you ever issue a second circular where you thought that the guardians had not done what you thought right and reasonable in granting a superannuation allowance? We embodied it in our circular.

107. But you issued no circular? No other circular.

108. Although I believe those cases of alleged injustice extended over a very considerable period of years? Yes.

109. Yet you issued no remonstrance to the boards of guardians pointing out the injustice of refusing superannuation allowances to parties who fairly were entitled to them? We issued no general circular. I am not prepared to say that there was no remonstrance.

110. It was only when Poor-law guardians, being the payers, became generous with their rates, that you issued the circular? When they so far exceeded what we thought was at all reasonable.

111. Then I may take that you issued it rather upon economical grounds than otherwise? Yes; the reasons are expressed in the circular, namely, justice to the rate-payers.

112. To the people who were paying the rates? Yes.

113. The Local Government Board issued a circular to the Poor-law guardians, who were the payers of the rates, pointing out that they were doing injustice to the rate-payers? Yes.

114. And so long as they were doing injustice to officials who were under their more immediate control, you issued no circulars? We did not issue any circular, but we embodied that in this circular when we issued it.

115. As a kind of makeweight? I do not say that; we took advantage of that circular to express our views upon the subject.

116. On what principles did you act in refusing those superannuation allowances which the Poor-law guardians granted? I have not a return of them, but I may state generally that we have compelled the scale to be adhered to, with the addition of a certain number of years, ever since the issue of that circular.

117. You say that you drafted your Bill upon the Civil Service Act of 1859, but you inserted the words "not exceeding" in the place of the words used in that Act; do you consider that the Civil Service scale of superannuation is a fair scale to be adopted with reference to union officers in Ireland? I do, certainly.

118. Without exception? Certainly; with additions in certain cases where there are special and professional services, in which cases we propose to give an addition.

119. What do you call special? I call special where the duties of the office are such that a man cannot enter upon them at a very early stage of life; he must attain a certain amount of experience before he is in a position to undertake the duties.

120. The scale of service is that adopted in the Civil Service Superannuation Act? Yes.

121. In point of fact, at present persons can enter the Civil Service at a minimum age of 16, while union officers are not eligible until they are 21 years of age? I believe the pay in some cases is greater than in the Civil Service on entry.

122. I am asking you about the Poor-law board; is it a fact that persons are eligible to enter the Civil Service at the minimum age of 16, whilst union officers are not eligible until they are 21 years of age? They are, under very special circumstances.

123. Is it not the fact that the salaries given to union

officers on entering the service are much smaller in comparison than those of Civil servants in every class? In the case of some of the officers they are, but not in the case of medical officers, and clerks of unions.

130. That the Civil Service, or take the Army and Navy; are not all their salaries much larger than those of union officers. Take my own district, Dundalk; the salary of the doctor is only £75 a year, and the highest salary in my union is £150 a year? But there are a great number of emoluments attached to the office. There is one-fourth in addition to the Public Health Act.

131. You know the class of men who are in that district, are they not, as a class, equal to any Army and Navy surgeons? Yes, certainly.

132. Are not their salaries much lower than those of the army and navy surgeons? I cannot say; I do not know what an army or navy surgeon has.

133. Are there any of those doctors who get 10s. 6d. a-day? Certainly, on the average, they do not commence at that.

134. Ten shillings and sixpence a-day, on the average, is the average at which an Army or Navy surgeon commences. Is there almost any district in Ireland, excepting, perhaps, Dublin and Belfast, where the surgeon receives at the present moment beyond 10s. 6d. a-day, or £180 a-year? I should think that there are very few, certainly.

135. Therefore my argument is substantially true, is it not, that the officers of the Poor-law Board in Ireland are much more underpaid than the average Civil servants? I daresay that may be so.

136. Then my conclusion is that it is unfair to allow the Civil Service superannuation scale to those underpaid officials? I can only say that from what I hear, I believe our union officers would be quite satisfied with that.

137. The union officers will be here to speak for themselves; I am asking your opinion? In my opinion it is perfectly fair to fix that scale, I think so from what has come to my own knowledge. I believe they will be quite satisfied with it; it is security that they require, that is all.

138. Is it not the case that in many instances union officers have served a period of over 30 years without an increase of salary, although they have had additional duties imposed, and in other instances the salaries have been reduced? I do not think there are many cases of salaries being reduced, but I have no doubt that there may be officers who have served 30 years without an increase of pay.

(To be continued.)

RED TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was greatly pleased to see lately in the columns of your journal two letters from the hands of Dr. Somerville and Dr. Welphly complaining of the great hardship caused to medical men by the manner in which red tickets are presented indiscriminately at any hour of the day or night. I am sure there are few dispensary medical officers who cannot bear full testimony to the abuse of their time and services merely through the carelessness of the friends of their patients. How frequently it happens to be sent for at 10 o'clock at night to see a patient who has been ill for days, or even weeks, with a request that we will go at once, as the patient is very bad and "afraid of the night." No matter what delay before obtaining the ticket, or presenting it when obtained, "the Doctor" is expected to attend at once.

It is a very common occurrence to be obliged to travel over the same ground, which may be several miles distant, two or three times a day. I do not see that it would entail any hardship on any one if a rule were made that, except in urgent cases, all red tickets should be presented by a certain hour, and in this I agree with Dr. Welphly, that 12 o'clock would be a fair hour, to allow persons at a distance full time to come in.

As a further proof of the acknowledgment of the necessity of such a rule, I have tickets in my possession the form of

which is, I believe, not now in use, bearing the following sentence: "This ticket should be presented before the hour of — o'clock," which form I think should be reintroduced and properly filled up.

I have myself been in the habit of not going out for the day until about 12 o'clock, in order to allow time for tickets to be brought in, and leaving any cases for which tickets may have been presented after my departure to be attended next day. I make this known as much as possible, and would advise others to endeavour to make the same rule as far as they can, though of course in the present state of affairs, I being a young man with a good many enemies always on the watch for an opportunity of being able to bring some charge against me, cannot make this a hard and fast rule. No one conversant with the duties of a dispensary medical officer can have any doubt of the many hardships to which he is exposed, without having so much unnecessary work imposed on him. My own experience, and I am sure it is the experience of the majority of my *confrères*, is that my work has frequently been doubled by the system of which we complain, and that I consider this a question of some importance, and trust the profession will do all in their power to shake off the imposition of so much unnecessary labour. Thanking you for kindly inserting this in your journal, which does us such good service in making known our grievances,

I am, &c.,

J. M. MARTIN.

Piltown, 15th September.

CARRICK-ON-SUIR DISPENSARY.

At the usual monthly meeting of the committee the hon. sec. to the committee read a correspondence in which a lady submits the following question to the Local Government Board:—

"Will you kindly inform me if there is any law by which a dispensary committee can have power to pay the car-hire for the dispensary midwife? At the urgent request of a committee of ladies, who knew the lives of poor women and children were endangered, the dispensary committee here appointed a midwife last year at £20 per annum; but the district is so extensive to which she is appointed that she cannot afford to pay car-hire. In some instances a donkey-car is brought, in which she is quite satisfied to go; but from the more distant places it is generally a messenger sent in on a horse or mule, and if he were to wait to return to fetch a cart or donkey-car the woman's life might be lost."

Mr. Grubb—Did the Local Government Board answer the question they were asked?

Mr. Walsh (chairman)—They did not.

Mr. Hearne said he was secretary to the committee. It was understood that the ladies' committee would provide a car where the patients were unable to procure one.

Mr. Rockett said it would be well to have Mrs. Travers called up, and have her show what amount she had actually expended in car-hire, and if she proved that in one year she had expended £5 he would be prepared to move that the committee recommend that her salary be increased £5 a year.

Mrs. Travers then came up, and stated that if one case per week turned up in which she had to provide a car it would eat up all her wages.

Dr. Wall—To simplify matters, what has car hire cost you since your appointment eighteen months ago?

Mrs. Travers—Here is the account of it.

Mr. Rockett—It only amounts to 13s.

Mr. Grubb—I thought it was much more.

Mr. Rockett—I thought £5 at the least.

Mr. Walsh—The thing is not regularly before us. Mrs. Travers has not made a formal application for either car-hire or an increase of salary. Let her make such an application if she wishes, at our next meeting, and we will consider it.

This course was then adopted, and the matter dropped.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

*Read and adopted at a Meeting of the Council, held 17th
October, 1882.*

Dr. ROBERT BROWNE (Chairman of Council) in the
Chair.

MR. CHAIRMAN AND GENTLEMEN.—Since the Annual General Meeting, in June last, the Committee of Council have held thirteen meetings. In August they adjourned, as usual, till October. The names of six new members have been added to the list, and one resignation has been accepted. The report of the Select Committee of the House of Commons on the "Union Officers' Superannuation (Ireland) Bill," dated 11th August last, has just been published, together with the minutes of evidence taken and an appendix. The report of the Royal Commission on the Medical Acts' Amendment Bills has also been published since the date of the Annual General Meeting of this Association. These reports are of special interest to the members of this Association.

THE UNION OFFICERS' SUPERANNUATION (IRELAND) BILL.

On the 22nd July last this Bill was read a second time in the House of Commons, and ordered to be committed. On the 5th of August the Select Committee was nominated, to consist of Mr. Attorney-General for Ireland, Mr. Healy, Mr. Justin M'Carthy, Mr. Meldon, Mr. Gibson, Mr. Fitzpatrick, Captain Aylmer, Mr. Biggar, Sir P. O'Brien, Mr. H. Gladstone, Colonel Tottenham, Mr. Mulholland, Mr. Callan, Mr. Greer, Mr. Findlater, and Mr. Day—sixteen members, five of whom to be a quorum. The Select Committee were empowered to send for persons, papers, and records. On 8th August the Solicitor-General for Ireland was substituted for the Attorney-General for Ireland as a member of the Committee. The Select Committee first met on 8th August, when Mr. Herbert Gladstone was called to the chair, and the Committee, having deliberated, adjourned to the 10th August, when Mr. Henry Robinson, Vice-President of the Local Government Board for Ireland, was examined. The Committee then adjourned till next day, when Dr. A. H. Jacob, as representative of the Irish Medical Association was examined. Mr. Henry Robinson was further examined, and Mr. Robert Stewart, member of Board of Guardians of Belfast Union; Dr. Thomas Joseph Moore, Medical Officer of Ardee Dispensary District; and Mr. Joseph D. Cope, Clerk of Rathdown Union, were examined. The Committee then deliberated, and agreed to the following special report, and report, viz. :—

SPECIAL REPORT.

The Select Committee to whom the Union Officers'

Superannuation (Ireland) Bill was referred have agreed to the following special report :—

Your Committee are of opinion that at this late period of the session it is not possible to complete the evidence which bears on the Bill referred to them; that it is therefore not desirable to proceed further with the said Bill during the present session, and that it be reported to the House without amendment, together with the minutes of evidence taken before them, and appendices. Your Committee further report that the Chairman and the Solicitor-General for Ireland, on the part of the Government, expressed their willingness to accede to the principle of the following amendments :—Here follow amendments having the effect—*a.* To enable boards of guardians to discuss the grant of pensions, such grant, however, being compulsory, and assessed according to the Civil scale of pensions. *b.* That the pension shall not be less than the said scale. *c.* To enable the Local Government Board, in an exceptional case, to reduce the pension below said scale, as set forth in following (that is to say) :—

New Clause 3.

"Whenever an application is made to the Local Government Board to sanction the grant to any union officer by a Board of Guardians, of a superannuation allowance or gratuity under this Act, it shall be lawful for the Local Government Board either to sanction or to refuse to sanction such grant, or to sanction the grant of a superannuation allowance or gratuity to such officer of such less amount than otherwise would have been awarded to him as the Local Government Board may determine, where the defaults or demerit of such officer in relation to the union service appear to them to justify such diminution."

The Committee of Council have pleasure in reporting that the principle of the most important amendments suggested by this Association has met with the approval of Government, which, in a great measure, is due to the tact and ability with which Dr. Jacob acted as representative of the Association. Concessions, of course, had to be made on all sides. It was conceded on behalf of Government—

1. That the granting of retiring allowances shall be compulsory on Boards of Guardians, subject to the sanction of the Local Government Board.

2. That every Union Officer who has served ten years or more, shall, subject to the approval of the Local Government Board, receive a pension of not less than one-sixth of his salary and emoluments for every year of his service in any Union.

On behalf of this Association, and the Union Officers' Association, it was conceded that the Local Government Board should be empowered to refuse to sanction any pension, or to reduce the ordinary amount where the defaults or demerits of the officer, in relation to the Union service, appear to the Local Government Board to justify such diminution. It was found absolutely necessary to make this concession (for which there is precedent in the

C.S. Supn. Act), in consideration of those offered on behalf of Government, and the Committee of Council have expressed their approval of Dr. Jacob's action in the matter by according him a warm vote of thanks. For the information of those who are not initiated in matters of this nature, it may be well to observe that unless a compromise were made, the Bill must have been abandoned, for more would not be conceded, nor less be accepted, on the part of Government. The Committee of Council consider that the Bill, as amended, will prove satisfactory, and they have reason to expect that it will be re-introduced early next session, and that it will probably be passed early in the coming year.

THE MEDICAL ACTS AMENDMENT BILLS.

The Royal Commission on the Medical Acts which, at the date of last Annual Report, was about completing its sittings, has since presented to Parliament its recommendations, and the report of the evidence taken by it. Amongst which will be found the testimony of Dr. J. W. Moore, who was requested to represent this Association, and of Dr. Jacob, whose views on the subject of medical reform are, in most respects, those which this Association has advocated. The Committee of Council are gratified to be in the position to report that the scheme of medical reform, recommended by the majority of the Commission, corresponds in its most important respects with that which this Association has supported, although some of the details suggested by the Commission are different from those of the plan usually accepted by medical reformers.

The Royal Commission recommends:—

(a.) That a central examination shall be held for each division of the kingdom, uniform, as far as possible, in the curriculum required, the standard of examination and the fee to be paid, such examination being held by an examining board, in which all the existing licensing bodies of that division of the kingdom are represented.

(b.) That the passing of such central examination shall be the sole qualification necessary for admission of a medical man to registration and practice, and shall supersede all the ordinary diplomas and degrees usually conferred by the Licensing Bodies as qualifications to practice.

(c.) That the General Medical Council be completely reconstructed, and its numbers reduced. Its members not being, as heretofore, appointed by the licensing bodies, but by the Central Board, in which the licensing bodies are represented.

(d.) That the opinions and interests of the medical profession at large be represented in the Council by six representatives, to be elected directly by the registered practitioners throughout the kingdom.

(e.) That the clauses for suppression of unlicensed practice, and for punishing those who make use of medical titles which they do not possess, shall be strengthened, and made more comprehensive, but that the practice of medicine by unqualified persons shall not of itself be unlawful.

The Committee of Council are of opinion that the recommendations of the Royal Commission are not sufficiently stringent as to the suppression of unlicensed practice for gain, which ought, in their view, to be strictly prohibited, but the Committee of Council can understand the indisposition of the Royal Commission to offer a recommendation on this subject, for which there might be much difficulty in obtaining the assent of Parliament. It appears also to the Committee of Council that strict uniformity of fees, curriculum, and examination is not adequately provided for in the scheme as recommended by the Royal Commission, and they are of opinion that no readjustment of medical education can be satisfactory or efficient which affords an inducement to the student to emigrate from the place of his education to seek a cheaper or educationally inferior qualification elsewhere.

On the whole, however, the Committee of Council are of opinion that the Association may be congratulated on

the prospect of medical reform held out by the report of the Royal Commission.

MEDICAL WITNESSES.

SCALE OF FEES UNDER JUDICATURE ACT.

In the last Annual Report (pp. 99-101) reference was made to the insufficiency of the fees proposed by the committee of judges to be allowed to medical witnesses in civil actions under the Judicature Act, and to the course taken, with a view to endeavour to obtain a higher scale of fees, but the Committee of Council regret to observe that the following is the scale of fees for medical witnesses contained in the "Rules and Orders of the Supreme Court of Judicature (Ireland) made the 1st day of June, 1882," as published in the *Dublin Gazette* of 27th June, 1882, viz:—

"In taxing the expenses and allowances of witnesses the taxing officer shall, in ordinary cases, have to regard the following scale:— * * * * *

E. For medical men:—

If resident within five miles of place of trial, or ten miles, if there is a railway for three-fourths the distance, per day, not exceeding £1 1 0

If beyond that distance, per day, not exceeding £3 3 0"

The protest made by the Council against the inadequacy of such fees, it therefore appears, has not had the desired effect, and the Committee of Council feel deeply aggrieved that such manifestly insufficient fees should be fixed for medical witnesses, who will often find that such remuneration will not cover the loss sustained through attendance at Court, to say nothing of its affording, as it ought, adequate recompense for services rendered over and above loss and the expenses incurred.

If the members of this Association will have the goodness to report to the hon. secretary the particulars of all cases of grievance occurring under these rules, there will, doubtless, soon be a sufficient number to form conclusive evidence to lay before the judges that the scale of fees is inadequate, and ought to be amended: this appears to be the only way in which redress can now be expected to be obtained.

The above-mentioned scale of fees refers only to medical witnesses in civil cases, and not to crown prosecutions. In crown prosecutions the Rule of the Attorney-General, dated 16th December, 1876, is still in force, and is to be observed by all crown solicitors and sessional crown solicitors. It is as follows:—

Rule—"When a medical witness is summoned to attend at sessions in the town in which he resides, the usual fee of one guinea is to be paid. If he be detained in court more than three hours, an additional fee of one guinea is to be allowed. When he is summoned to attend at any other town he is to be paid two guineas for every day he is necessarily kept from home, together with his travelling expenses and hotel charge, not exceeding 15s., for each night he may be absent."

The Committee of Council are advised that the term "Sessions" includes Petty as well as Quarter Sessions.

In crown prosecutions the fees of a medical witness are paid by the Crown, and no more than the amount fixed by the scale can ever be obtained, but in civil cases medical witnesses frequently have opportunity of arranging with the suitor, in whose behalf the evidence is to be given, as to the amount of fees to be paid before the case comes for hearing, and any such arrangements entered into would, the Committee of Council are advised, be a legal and proper contract which could be maintained at law, notwithstanding the scale of fees above referred to.

VACCINATION.

With reference to the subject of reform of the Vaccine Department of the Local Government Board of Ireland, suggested by the Council, and brought under the notice

of His Excellency the Lord Lieutenant (*vide* last Annual Report, pp. 95-99), a letter has been received from the Under Secretary, stating, in effect, that the Local Government Board (to whom the communication had been referred) saw no necessity for any change in the present arrangements being made.

The Committee of Council will again bring the suggested reforms under notice when they expect to be able to adduce abundant evidence to show that the adoption of all their suggestions is not only feasible but positively essential to the interests of the public; and they feel in duty bound to revert to the subject and press it, as they cannot pass in silence the present system, which misleads the public to believe that the arrangements connected with public vaccination in Ireland are satisfactory, while they reflect discredit on member of the profession, and fail to afford to the public the full protection against small-pox intended to be provided by the Legislature.

The following letter was addressed to the Under Secretary from whom an acknowledgement of its receipt was promptly acknowledged, viz:—

Irish Medical Association,
Royal College of Surgeons,
Dublin, July 5th, 1882.

SIR,—In reply to your letter, No. "26,418" of 13th ult., I am directed by the Council of the Irish Medical Association to state for the information of His Excellency the Lord Lieutenant, that the alterations suggested by the Council in my letter of the 29th April last, to be made in the Vaccination Department of the Local Government Board did not reflect adversely on the management of that department. The Council merely desired to express their opinion that, in the public interest, it is essential that the scope of that department should be greatly increased by a reform of its powers and constitution. The Council have no reason to think that the Vaccine Department was not satisfactorily worked so far as the present system permits, but the Council are thoroughly convinced that until a complete reform be made with regard to the supervision of public vaccination, and the supply of animal or humanised lymph as desired, it is quite beyond reasonable hope to expect that the condition of public vaccination in Ireland can possibly be satisfactory. The present system of supervision is not effective, and the result is that there is no proof of successful vaccination in an enormous proportion of the population, and no sufficiently satisfactory evidence that such vaccinations as are certified to have been successful, are as thoroughly protective as possible. The reform suggested by the Council is almost precisely an adaptation of the system in vogue in England during many years—a system which there is not only found to be necessary, but economical. The Council are aware that such a system is at least equally needed in Ireland, and they are confident it would prove as satisfactory in result from all points of view; they have, therefore, felt it their duty to bring the subject under the notice of His Excellency the Lord Lieutenant. I am directed to express an earnest hope that His Excellency may be pleased to inquire fully into the subject with a view to extension of the scope of the Vaccine Department of the Local Government Board for Ireland in order that the public may as thoroughly as possible derive the advantages intended by the legislature to be conferred for their protection against small-pox, and the avoidable sorrows and enormous expense to the rates, which, under the present system, are entailed by every visitation of that dread disease.

I am, Sir,
To R. G. C. Hamilton, Esq., Yours, &c.,
Under Secretary, JOHN H. CHAPMAN,
Dublin Castle. Hon. Sec.

CONSULTATION FEES IN DISPENSARY PRACTICE.

In the report adopted by the Council on 1st November, 1881 (pp. 14, 15), and that adopted on 4th April last

(pp. 68, 69), reference was made to a case in which a dispensary medical officer, on the necessary authority of the relieving officer, was called upon to assist another dispensary medical officer at a difficult case of midwifery, attended on a visiting ticket. The consultant had applied to the board of guardians for a fee of two guineas, which was refused, on the ground that the guardians were in the habit of giving only one guinea in such cases; the Local Government Board had been appealed to, but had declined to interfere, and the Committee of Council had advised legal proceedings to be taken to recover the fee claimed, to which course the support of this Association was promised; however, when the legal proceedings were commenced, the guardians settled the claim, without taking defence, by paying the fee of two guineas and the costs of the solicitor, who had been employed at the instance of this Association.

As disputes of this nature not unfrequently occur, the Committee of Council deemed it advisable to state the case for an opinion of Council, which was submitted to George R. Price, Esq., B.L.

The following are the questions which were put to him, and his replies thereto:—

1. Counsel will therefore please advise Querist whether, in his opinion, Dr. . . . is not entitled to receive his usual and proper consultation fee from the Board of the . . . Guardians, and that in the event of Dr. . . . establishing the fact that £2 2s. would be the proper remuneration for his services as consultant, the Guardians are not legally bound to pay him the same?

1. I am of opinion that Dr. . . . is entitled to receive his usual and proper consultation fee from the relieving officer, who should be furnished by the . . . Board of Guardians with the necessary funds for the purpose; and, upon its being established that £2 2s. is the proper remuneration for Dr. . . . services rendered on this occasion, the Relieving Officer is, in my opinion, legally bound to pay him, and the Guardians are legally bound to furnish the necessary funds to the Relieving Officer.

2. Should Counsel be of opinion that Dr. . . . can legally recover his fee of £2 2s. Counsel will please advise what proceedings, and against whom, should be commenced by Dr. . . . or the Irish Medical Association on his behalf, in order to obtain payment of same?

2. The proceedings should be against the Relieving Officer, in my opinion, and should be either in the County Court by Civil Bill, or if that be not considered a satisfactory tribunal, then by an action in one of the Superior Courts.

3. Counsel will also please advise whether it would be competent for the Irish Medical Association to institute proceeding by Mandamus or otherwise in the Queen's Bench Division of the High Court of Judicature, with a view of having this question settled once for all.

3. I am of opinion that a proceeding by Mandamus in the Queen's Bench Division might be maintained against the Board of Guardians at suit of Dr. . . . to compel the Guardians to furnish the necessary funds to the Relieving Officer, if upon demand being made, they refused to do so.

It appears to me that the present case arises, and must be dealt with, under Sec. 7 of the Poor Relief Extension Act of 1847 (10 & 11 Vic. c. 31). I do not find any other statutory provision under which any medical aid, other than that of the regular dispensary medical officer of the district, could be supplied at the expense of the guardians or of the rates. There is nothing on the subject of extra medical aid in the Medical Charities' Act of 1851, and the provisions as to extra medical services contained in the statutes relating to public health have no applica-

tion to such a case as the present. By Sec. 7 of 10 & 11 Vic., c. 31, it is enacted that every relieving officer shall have power to give provisional relief in any case of sudden and urgent necessity, by affording, amongst other things, immediate and temporary relief in medical attendance, until the next ordinary meeting of the guardians, at which meeting he is to report the case, and the guardians of the union shall furnish the relieving officers with the necessary funds for affording relief in manner aforesaid. This Act makes the relieving officer the person who is to give the relief in cases of urgent necessity, and he is, in my opinion, constituted the judge of the necessity, and authorised to enter into the necessary contract for the purpose, subject to the duty of reporting to the guardians, who will, of course, control his action if improper; and the relieving officer in this case having given his authority, must be held to have contracted with Dr. . . . to pay him whatever would be the proper remuneration for his services. The guardians are bound to furnish the relieving officer with the necessary funds for affording such relief. This clause appears to indicate clearly that the relieving officer is the person directly liable to the person who renders the services which constitute the relief, to pay for these services, and in the absence of a special contract as to the amount of payment, he would be liable to pay a reasonable and proper amount. I do not think that the guardians are under the section directly liable to the person rendering the services. It might be said in the present case that they have admitted liability by offering to pay something, but that not having been accepted, being considered inadequate, cannot, in my opinion, be relied on as an admission of liability, and it is to be observed that the offer of payment came to Dr. . . . from the relieving officer, who, according to my view, is the person liable to the doctor. If the guardians should neglect or refuse, after demand made, to perform the duty imposed on them by statute, of providing the necessary funds for affording relief, then I think that Dr. . . . being interested in the performance of that duty, inasmuch as he is entitled to the amount to be paid, would have a right to obtain from the Queen's Bench Division a Writ of Mandamus ordering the guardians to perform that duty, but the simplest mode of proceeding would be to sue the relieving officer.

Leeson Street, Dublin.
May 7, 1882.

GEO. R. PRICE.

SLIGO DISPENSARY.

REPORT read of the Sligo Dispensary Committee.

Resolved, that Dr. Palmer being unwell, Dr. Martyn be appointed as his *locum tenens* for a month, at £3 3s. per week.

Mr. Higgins remarked that the only objection was his having gone away without leave of absence, and without any *locum tenens* having been appointed.

Mr. Walker—With regard to the *locum tenens*, it should not go forth that such was appointed at a salary of three guineas a week. I would make it two guineas per week, and one guinea per week horse and car hire. This is what we did in the Carney and other districts.

Mr. O'Brien considered that the care hire was an imaginary thing, for in the course of his duties as a *locum tenens* it might happen that he would not have to spend the money on car hire. The ratepayers, he thought, were heavily taxed enough without paying for car hire when such was not required—at all events not to the extent of £1 per week.

Mr. Walker said his proposition was really in a measure to meet it, for he considered this was not a time for paying large salaries, even to substitutes. Of course the board knew that a medical man could not keep a horse and car for nothing.

Mr. Brennan—Let the doctor who is getting his leave of absence pay for the horse and car hire for his substi-

tute, and not leave the heavily-taxed ratepayers to pay for it.

Chairman—The doctor is away now, and we cannot question him upon that point.

Mr. Walker—We have already passed a resolution at this board that no medical officer of this union is to have more than a month's leave of absence during the year under any circumstances.

The Chairman considered Mr. Walker's proposition as to the two guineas a week and a guinea for car hire would meet the general wish of the board.

ATHY UNION.

MISTAKEN IDENTITY OF A CORPSE.

MR. O'BEIRNE—Before the guardians separate, I wish to call attention to a disgraceful scene that occurred in this house about a fortnight ago. It appears that there was a female patient in the hospital here, and information was conveyed to her relatives and friends that she had died. A crowd of people came up to the house for the purpose of taking the corpse, but instead of taking the woman they took home a dead man, and when they found out their mistake they took the man's body back again, and, as I am informed, this crowd of people, or some of them, behaved in a most unseemly manner, clamouring for the body of the woman, who after some time was found not to be dead at all. Now I deliberately say whoever was in fault, and allowed that most disgraceful scene to occur, is not fit to remain in the position he holds, whatever it may be.

Chairman—Whose business is it to see after the proper care of the dead?

Master—It is the porter's business, but he being sick, I was discharging his duty, and I was responsible. It happened through my neglect.

Chairman—You should not take so many things on your back. You should have represented these things to the board, and someone would have been appointed to do the porter's business. But, above all, so serious a matter should have been reported to the board.

ASSESSMENT OF POOR-LAW SUPERANNUATION.

DR. B., co. Wexford, writes:—

DEAR SIR,—Will you be kind enough to let me know if the time of the dispensary medical officers while attached to dispensaries before the commencement of the Medical Charities Act is to be taken into account in the fixing of superannuation? If not, a great wrong will be done to the old men, and I am sure a clause reserving the time for them would not be objected to.

I have been a dispensary medical officer since October, 1839, twelve and a-half years under the Grand Jury, and since 1852 under the Medical Charities Act.

[It is part of the superannuation scheme lately before Parliament that a general superannuation rate shall be levied throughout Ireland, and that pensions shall be a charge on this rate, not on the local taxes. If this intention be carried into effect, the entire service of the officer in one or more unions will be counted towards his superannuation allowance. Thus the obvious injustice of requiring a board of guardians to pay pensions in respect of services given to other unions is got rid of. Our correspondents may rest satisfied that the point will not be overlooked by the Irish Medical Association in working for superannuation in next session of Parliament. —ED.]

IRISH POOR-LAW INTELLIGENCE.

ATHY UNION.

OUT-DOOR RELIEF.

Mr. R. Lalor—I wish to ask, Mr. Chairman, while the relieving officer for Castledermot is here, has the dispensary doctor power to give any amount of relief he wishes?

Chairman—The relieving officer has discretionary power which is never interfered with, and I think very properly.

Mr. Lalor—The reason I ask is, I know of a case in Castledermot, where a man got 18s. worth of provisional relief, and I don't think the man was destitute.

Relieving Officer—In that case, the man was suffering from typhoid fever, and I gave the relief on the certificate of the doctor.

Dr. MacCabe—The regular way to bring that matter before the board is, when the relieving officer considers a person entitled to provisional relief, he gives it for one week. He is bound then to report the matter fully to the guardians at their next meeting, when it is the guardians' business to call on the relieving officer for a full explanation of all the circumstances of the case, and they are then to determine whether the relief is to be continued or discontinued.

Chairman—Let it not go before the public that the doctor has power to order an unlimited amount of relief. He should be guided by the information given to him by the relieving officer, as to the fitness of the case.

Dr. MacCabe—The utmost the doctor can do is to recommend. But I consider it would not be well for the relieving officer to refuse the recommendation of the doctor; at the same time, the doctor should be guided by the information received.

Mr. Lalor—I repeatedly get recommendations from the doctor to get relief for people, and I found on inquiry that they were better off than many of the people who had to pay the rates.

Dr. O'Neill—My experience as a dispensary doctor for sixteen years is, that it is the greatest abuse to give this large amount of provisional relief, especially to people suffering from typhoid fever, for I invariably found that it was the families of the patients who got the major part of the relief. I would always recommend their removal to hospital, where every convenience exists for their proper treatment.

The matter dropped.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF OCTOBER, 1882.

OCTOBER 2nd.—Irvine, J. J.; 19 Northbrook Road, Dublin; Lic. R. Coll. Surg. Irel. 1881; Lic. and Lic. Mid. K. Q. Coll. Phys. Irel. 1882.

6th.—O'Reilly, M. F.; Oldcastle, co. Meath; Lic. K. Q. Coll. Phys. Irel. 1882, Lic. R. Coll. Surg. Irel. 1882.

7th.—Whitestone, H. L.; Ballinacally, co. Clare; Lic. R. Coll. Surg. Irel. 1880.

7th.—Houghton, J. F.; Loughlinstown, co. Dublin; M.B. Univ. Dub. 1876, M.D. Univ. Dub. 1881, Lic. and Lic. Mid. K. Q. Coll. Phys. Irel. 1876.

12th.—Boyd, Walter; Walworth, Grand Canal, Dublin; Lic. R. Coll. Surg. Irel. 1881, Lic. K. Q. Coll. Phys. Irel. 1882.

13th.—Scott, J. A.; 25 Idrome Terrace, Blackrock, Dublin; Lic. R. Coll. Surg. Irel. 1881, Lic. and Lic. Mid. K. Q. Coll. Phys. Irel. 1882.

20th.—Griffin, J.; Newcastle, co. Limerick; Lic. R. Coll. Surg. Irel. 1882.

20th.—Daunt, J. G.; 27 Bachelor's Quay, Cork; Lic. R. Coll. Phys. & Surg. Edin. 1882.

20th.—Stock, M. H.; Broadstone, co. Dublin; M.D. R. Univ. Irel. 1882.

23rd.—Harrington, J. M.; Tralee, co. Kerry; Lic. R. Coll. Surg. Irel. 1882, Lic. and Lic. Mid. K. Q. Coll. Phys. Irel. 1882.

24th.—Montgomery, W.; 12 Parliament Street, Dublin; L.A.H. Dub. 1882.

25th.—Holmes; Athlone, co. Limerick; M.D. and M.Ch. R. Univ. Irel. 1882.

26th.—Follows, W.; Wolverhampton; L.A.H. Dub. 1882.

27th.—French; Ballygar, co. Galway; Lic. R. Coll. Surg. Irel. 1880, L.A.H. Dub. 1882.

30th.—Keane, M. W. A.; Hampstead, Glasnevin, co. Dublin; Lic. R. Coll. Phys. and Surg. Edin. 1882.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT
COMMITTEE OF THE HOUSE OF COMMONS, 10TH
AUGUST, 1882.

(Continued).

Mr. HENRY ROBINSON'S examination continued.

209. One operation of the present system is that men who have become inefficient by reason of age and infirmity still struggle on in their situations, although they feel unable to discharge the duties properly, and they continue to discharge the duties in an ineffective way, without advantage to the public service; is not that so?—Yes, I believe that many do that.

210. Is not that, under the present system, a thing that is not unlikely to happen?—Yes, I should say it might be likely to happen.

211. Was not that a state of things that would be likely to happen under the existing system?—Yes, I have heard many instances quoted of officers who, under the present system, were unwilling to retire, but those cases will be brought up by the officers themselves.

212. In the Kilkenny Union I see there is one officer of 63 years of age and 18 years' service, and another 70 years of age and 17 years' service, who were both refused the superannuation, and it is stated that "a late relieving officer continued in office until his death who would have

resigned some years previously from general debility could he calculate on being superannuated; and at present another relieving officer, 64 years old, with 27 years' service, would resign if he were sure of being superannuated, feeling that he is not able to perform the duties satisfactorily?—That is stated by the clerk of the union.

215. Mr. Meldon. I do not ask as to the truth of it, but is not that a state of facts which is likely to happen under the existing system?—Yes, from statements made to me; there are many statements of that sort, but you will get full information upon that point from other witnesses.

216. Mr. Healy. You stated that you considered the Civil Service scale a better one than the existing one, generally speaking?—I think it would work more satisfactorily.

217. May I ask if, in issuing the circular, you chose the Civil Service scale for want of a better?—No, we thought the Civil Service was a very fair scale. It had previously been adopted in England, and had been adopted for other officers in Ireland, and by Act of Parliament with regard to the officers of vestries and other boards in the metropolis.

218. In answer to the honourable Member for Louth, you pointed out that there were three points upon which the authorised Civil Service scale is not the Civil Service scale. The first is with reference to the words "not exceeding." In the Bill the word "of" occurs; secondly, you showed that the age of the Civil servants will be much lower than in the case of Poor-law officers; and thirdly, you admitted that the salaries were lower. In reply to the honourable Member for Kildare, you stated also that the Civil Service scale is not compulsory any more than the present?—I gave a rather doubtful opinion upon that. I said I believe it is subject to the control of the Treasury; as a fact, the pensions are always referred for sanction to the Treasury.

219. I have looked through the Act of 1859 to find where it says that the sanction of the Treasury must be obtained, but I failed to find it; and for the purpose of examination we will assume that it is not in the Act?—I am certain as to the practice.

220. I am speaking of the actual words in the Act?—So I understand.

221. The Civil Service scale admittedly differs in three important points, namely, the words "not exceeding," the age of the applicant, and the lower salaries. Then there is also the question of compulsion; these three or four points appear to me to be the *corpus* of the Civil Service scale; could you show me in what respect you preserve in this Act the authorised Civil Service scale except as a matter of mere figures; I gather from your examination this: it appears to me that while you retain the skeleton of the Civil Service scale, the *corpus* is actually gone, because the words "not exceeding" come out, the age of the applicant, which is a material question in the matter of sixtieths, comes out, and you admit that the salaries are lower; will you tell us, excepting in the mere mechanical arrangement of the figures, how much is left of the Civil Service scale?—We have adopted the figures because we think them sufficiently fair, and we believe that the officers would be perfectly satisfied with it, and we have adopted the present Bill to remedy the existing state of things under which the guardians refuse to give pensions in many instances in which the officers have deserved them, in our opinion.

222. You issued the circular, I understand, upon the basis of the Civil Service scale?—Yes.

223. Seeing that that is altogether an erroneous statement, because the four important points that I have touched upon are altogether washed out in your proposed Bill, leaving, as I understand, only a very pale reflex of the Civil Service scale, and, as I would say, not the Civil Service scale at all, except in the matter of sixtieths; can you show me where the Civil Service scale is in the Bill

except in the matter of sixtieths?—The Bill authorises us to add a certain number of years, and we shall use our discretion as to the certain number of years to be added.

224. Did not you say just now to the honourable Member for Louth that this discretion as to the number of years would only come in on exceptional circumstances such as you mentioned, of gentlemen who could only commence their services at a certain age?—That would apply to officers who cannot enter upon their duties at a very early age.

225. Therefore, your contention, by which you support the claim to give the Civil Service scale, only applies so far as the alleged specialists come in?—It applies to any officer who cannot enter upon the duties of the service at an early age; it enables us to add a certain number of years to his service.

226. You state as a modification of what has been brought out, that this Civil Service scale is not at all in existence in the Bill; that the Board can add a certain number of years?—Yes.

227. Was it in the mind of the Board when they drew up the particular qualification, that this clause should apply to any but medical officers?—Clearly; I cannot say what the Board would do, but following the precedent of the Treasury, we should fix the class of officers who are entitled to additional years to be added to their service.

228. Of the entire class of union officers, you think that the special qualification which you mention in extension of non-fulfilment of the Civil Service scale would apply to the clerks of unions and medical officers?—And masters.

229. You admitted to the honourable Member for Louth that you were not willing to put in the words "not exceeding"?—I stated that I should not object to its being omitted, provided that we had power to deal with an exceptional case, and that we are not placed in a position that we must either refuse altogether our sanction of such sum, or give what we think excessive.

249. As regards lower salaries, is there any limit on the part of the guardians except the discretion of your board to the salaries which may be given?—No, there is no limit except our approval.

251. Let me come to the fact that as regards the age of the applicant, and the lower salaries, there can be no parity with the Civil Service scale; the Civil servants, as I gather from my reading of it, can put the Act in force after 10 years' service; they can go and demand the benefit of this Act?—Subject to the approval of the Treasury.

252. Can you point out in the Act where the "approval of the Treasury" is mentioned?—I do not say that it is in the Act, but as a matter of practice it is so.

253. If the Treasury refused could you not compel the Treasury to act up to the law?—It may be in some former Act; I cannot answer that question now. I tell you what the practice is, that the Civil Service officer's years of service must be sent to the Treasury, who determine his pension.

255. Are you aware from the practice of the Civil Service that it is customary to refuse pensions; have you ever known a case in which an officer who had served 10 years was met with a refusal by the Treasury?—I cannot call one to mind.

256. Does not that go to show that the Civil Service scale is, in point of fact, compulsory?—The union officers would be placed exactly in the same position; they would be entitled to demand their pension and receive their pension; if the guardians do not give it, it is subject to appeal to us, and we should have no hesitation in granting it if the officers had served us faithfully.

257. The two cases are different; in the Civil Service scale they can get it whether the Treasury or anybody else likes it, or no?—I am not prepared to say whether they can or not.

258. If there is no such requirement in the Act of Parliament would you be prepared to abrogate the same provision in your Act, "from and after the passing of the

Act the Local Government for Ireland may, if they think fit ;" if you found that there was no appeal to the Treasury, and the Treasury had no controlling power, would you be prepared to follow the practice of the Civil Service scale and make this compulsory also ?—I stated before that if we are to be allowed to deal with special cases, I should not object to the alteration suggested.

273. With regard to the circular which you have issued, did you issue it as the result of your observations, or was it from a motive arising upon a particular case. You issued the circular in 1881 ; do I understand that this circular was issued upon a particular case ?—Yes, one particular case ; I did not say so before, but it was one particular case which directed our attention prominently to it.

274. It was not upon your general experience ?—We looked more closely into it. Our attention was particularly directed to it by one case, and upon that we took the whole subject into consideration.

280. I believe it is the case that the workhouse teachers and doctors at the present time get half their salaries from the State ?—The guardians receive back from the Government one-half of the salaries of the medical officers, and the whole of the salaries of the teachers.

281. Although then all the workhouse teachers' salaries and half the dispensary doctors' salaries are paid by the State, you propose that the entire pension of those two officers should be borne by the ratepayers ?—It is so now. There is no change whatever proposed in that respect.

284. You would not be prepared to recommend with a view to those two officers, the teacher and the doctor, that any of their pensions should be borne by the State as well as their salaries ?—No, I do not see any cause to make a change in the existing law upon the subject, and I doubt whether it would be sanctioned by the Government.

289. Might the Local Government Board put on for general pensions a 1d. in the pound, or 2d. or 6d. ?—We should put in what we estimate is required for the year. We are authorised by the Act to levy what we estimate is required.

290. And you estimate it, roughly speaking, at about a farthing in the pound ?—No, I do not estimate it as much as that ; a farthing in the pound is required to pay the accumulated pensions of 15 years.

291. You think that it will not come to a farthing in the pound as a general thing ?—Certainly not. In the first year it would not come to ½d. in the pound.

292. Would you be prepared to accept an amendment in the Bill to the effect that the Local Government Board should not have power to extend the national rating above a farthing in the pound ?—No, I should not do that. When we come to the end of 14 or 15 years we may arrive at a farthing in the pound.

294. This Bill is recommended to Parliament on the understanding that it is very unlikely that the rate will exceed more than a farthing in the pound ?—It is to substitute a rate for the rate at present struck in individual unions ; the rate over the whole country, on the average, would not be more than at present, but it will come off the rate evenly in Ireland, instead of unevenly off certain unions as at present. I do not think there is any necessity to put such a provision as that in.

295. You are not willing to agree to the insertion of a provision in the Bill, that the poundage rate to be levied by the Local Government Board, over the whole of Ireland, shall not exceed a farthing in the pound ?—Yes ; if we get to a deadlock, there would have to be a new Act.

298. And fresh legislation upon the point ?—Yes.

300. The reason I asked the question is this, that complaints have been made in many cases by the guardians that there is a tendency upon the part of medical officers to apply for extra emoluments, and they having an active and vigilant association, and being powerful and influential persons, most of them are enabled to get higher pensions and salaries than the general run of the officers ; for instance,

as I have shown, the pensions of medical officers from 1865 to 1880 have averaged £68, while the pensions of other officers have only averaged £26 ; I believe it is the fact there is always one member of the medical profession upon the Local Government ?—Yes.

301. Has it always been so in your experience ?—Since the passing of the Medical Charities Act it has.

302. And the medical officers have a very active and effective protective association, have they not ?—Yes.

303. Centred in Dublin ?—Yes.

304. And it is also the duty of the Local Government Board to listen to the representations made to them by every association affecting the poor law ?—They give every attention to everything laid before them.

308. And you do not think that there is any reason to fear that the Local Government Board is likely upon that account, a third of its members, if I may so say, being a doctor, that more pressure can be brought to bear with regard to the advantages of the medical profession than with regard to the general body of the officers ?—I have no apprehension whatever on the subject.

312. Therefore, so far as that amendment is concerned, it it simply waste paper ?—The guardians will like it better ; and the guardians, when an appeal is made from their decision, will be able to set forth the grounds upon which they arrive at their decision. I think it is well to meet the wishes of the guardians, and they have been yielded to.

313. Simply as a matter of sentiment ?—I do not say that.

314. With regard to the result you admit there is no practical difference ?—In the result there will be no practical difference.

330. The honourable member for Louth asked you with regard to the comparative emoluments of dispensary doctors, and union surgeons, and physicians, compared with the emoluments of Army and Navy surgeons ; with regard to that, is it not the case that it is customary for the different grades of medical men under the poor law to have private practice as well ?—Yes.

331. And with regard to the naval and military doctors, they have not private practice ?—That is so ; at least I believe they have not ; I can tell you about the union officers.

332. They do not give their whole time ?—No.

333. Take the case of the Belfast Union ; I believe it is the largest union in Ireland ?—One of the largest.

334. They do not object to give pensions ?—They do give pensions.

335. And they have a very large staff ?—Yes.

336. Can you give me any idea with regard to the number of persons who get pensions from that board at at present ?—There are six officers at present receiving pensions.

343. Do you think that the real reason why so few superannuations have been given in the Belfast Union, with regard to medical men, is because they have simply used their position as officials in connection with the workhouses as a stepping-stone to professional preferment ?—I cannot say what are the motives that influence the board of guardians.

344. But do you know, as a matter of fact, that the medical men generally voluntarily give up their positions upon the board without any fault being found with them ?—I dare say that is so ; I do not know it as a fact.

345. Do not you know that with regard to other classes of officials, not medical men, the real reason why they give up their positions is because the great majority of them are forced to resign ?—That I cannot say.

357. With regard to the dispensary doctor, it is a cumulative salary, is it not ?—It consists of his salary and vaccination fees, and the amount paid under the Public Health Act ; they are the principal things. They are the registrars of births, deaths, and marriages in many instances ; it is not necessary that they should be, but they

are in most cases, and they have fees for the examination of lunatics, and so on.

358. Do they get pensions for all?—No, they only get pensions upon their salaries, vaccination fees, and payment under the Registration Acts; they do not get pensions now in respect of their salaries under the Public Health Act, and, as I said before, it was probably an oversight in the Act; but that is so.

381. Mr. Findlater. With reference to the words "not exceeding," in the 17th line, do not you think from your experience it would be very undesirable to take away the discretion given by the amendment so as absolutely to entitle an officer to a proportion of his salary, totally irrespective of the manner in which he has discharged the duties of his office?—I have already answered that question. I prefer the Bill as it stands, leaving the words in, but to the other course, as an alternative, there is not an insuperable objection if a proviso is added giving us controlling power in exceptional cases.

383. I think you said that you had the power of adding a certain number of years in calculating the service?—That is in the Bill.

384. You said that in cases where a certain amount of experience, and time, and expense had been spent in acquiring knowledge before they are appointed, you have taken that into consideration; it struck me with reference to the hospital nurses that, of course, they could not be appointed at such an early age if they had to acquire that experience, and yet I think you said they would be excluded?—That is a subject for consideration. I could not give a decided opinion upon the subject, because it will have to be decided by the whole Board, including the President, but I mentioned the three classes of officers who I thought would come under it, and no doubt there may be others; and the point you raise is a very fair question for consideration.

385. Mr. Daly. You have put in the circular of November the 25th?—I have.

386. You also put in the English circular; what is the date of that?—The 14th of December, 1880.

387. You said that they ran pretty much on parallel lines, but that there was a distinction between them; what is the exact distinction between them?—I said the circulars were pretty nearly the same; the distinction between them is that at the end of our circular we urged upon the guardians the necessity of granting pensions where they have hitherto refused them.

388. That is to say, you sought in the Irish circular for the power of compelling the guardians to grant pensions that the English Local Government Board does not seek?—No, we did not seek that power; we had no such power; it was merely giving advice.

390. Is that power at present vested in the English Local Government Board?—No, not at present.

391. Then, in effect, this Bill, if it becomes law, will allow the Board sitting in Dublin, to exercise control over the payment of the rates of the Irish guardians, when no such power is sought by the English Local Government Board over the English boards of guardians?—I have answered that question before; I say that it is entirely a question for Parliament whether they will give us that power or not.

392. We have it in evidence that you approve of this Bill?—Certainly.

393. You approve of it, and the Local Government Board approve of it?—Certainly.

394. And, in effect, in the provisions of this Bill you seek to obtain the power?—Yes.

395. Then I may take it that, as regards the English Poor-law legislation, no such power at present exists in England?—That is so.

396. I wish to refer you to Clause 9; I see amongst

the persons who, under this Bill would be entitled to superannuation, are persons who are paid by a percentage upon the collection of rates?—Certainly.

397. Then the Bill, if it becomes law, will enable the Local Government Board in Dublin to compel boards of guardians in Ireland to grant pensions to persons who are really officers paid by a percentage on the collection of the rates?—Yes.

401. How would you obtain information from those persons other than that they have faithfully fulfilled their contracts?—It would be competent for the boards of guardians if they refused to give any pension, and an appeal is made to us, to appear in defence of their own decision, and give the grounds of it, and they naturally would do so. We should require them to state the grounds upon which they think these persons should not obtain pensions, and they would appear and give their reasons, and we should decide upon the reasons.

402. Do you think it reasonable, with the guardians paying out the money of the persons by whom they are elected, that there should be a necessity for an appeal to persons who have no knowledge of the matter?—That is the only way we can devise for securing pensions to officers after long service.

403. You have power at present, if this Bill does not become law, I understand, to control the sum awarded for superannuation pensions by the board of guardians?—Yes.

404. One of your reasons that you adduce in your early examination was, that in many cases boards of guardians did not accord any superannuation to officers who were worthy of it?—Yes.

405. You adduced as a reason for that some instances which you thought of peculiar hardship?—Yes.

432. The honourable Member for Kildare asked you a question to the effect that one of the grievances under which officers laboured was, that the question of their superannuation became a question of popularity. That was the effect of it. The common sense meaning of this question was, that a man's chance of being fairly treated by the board of guardians of the union, when he came to apply for his superannuation allowance, would depend upon the popularity and estimation in which he was held?—To a certain extent.

433. The Bill proposes to give the Local Government Board a controlling power over that?—Yes.

434. Taking into account that at present the elections of guardians are annual, that the proceedings of boards of guardians are public, and that the guardians, if they be not negligent of their duties, are conversant with the duties of the officers who are discharged; I would ask you whether those gentlemen on the 163 unions in Ireland, are not better judges of the efficient manner or inefficient manner in which those duties are discharged, than a body of gentlemen resident in Dublin who can only judge of the manner in which the duties are discharged by official reports?—I have answered that before, I think, to the effect that they (the board of guardians) have no doubt more opportunities of personal observation; but that we have perfectly sufficient knowledge of the officer's conduct, and would obtain still further knowledge of it in order to enable us to determine whether the guardians were justified in refusing to give him any pension.

436. If an officer performs his duties in respectable mediocrity, and does not commit any fault of omission or commission, and is thereby not reported, then, in effect, your knowledge in the Local Government Board of that officer is simply that he has never been reprimanded?—I stated before that it was my opinion that if an officer discharged his duty sufficiently satisfactorily to be retained in office, he is entitled to superannuation.

(To be continued.)

IRISH POOR-LAW INTELLIGENCE.

ENNISCORTHY UNION.

DISPENSARY CONSULTATION FEES.

A BILL from Dr. Drapes for the payment of £2 2s. for attending, with Dr. Bestall, a dangerous case near Ferns, was submitted.

Mr. Power—Did we not pay him to discharge all the duties of that dispensary, and why does he send in a bill for £2 2s. now?

The Clerk—He is not one of our officers at all. Dr. Smith was unwell, and he appointed Dr. Bestall as a *locum tenens*, and Dr. Bestall called in Dr. Drapes to assist him at a dangerous midwifery case, for which you have a bill for £2 2s.

Mr. O. Doyle—I believe he is entitled to call in another medical man to assist him in such cases.

Mr. Power—Is it paying three doctors to do the one work you are?

The Clerk—We are not paying three doctors. It was only on this occasion of the very bad case that Dr. Drapes was called in, and a doctor has a right to appoint a *locum tenens* when ill.

Mr. Power—Mr. Chairman, is it legal for a doctor to call in another whenever he likes, and make the poor ratepayers pay for him?

The Chairman—I can't say if it is legal, but I know it has always been done since I became a guardian of this Union.

The Clerk, in reply to the Chairman, said it had been always done.

Mr. Power—If it is legal pay it to him; but, if it is not, don't.

Mr. Stafford—Why should Dr. Bestall take it upon himself to call in a strange doctor, and one who lived so far away from him?

Mr. O'Farrell—That's the sense in which I took the matter.

Mr. Power—He had no right to do it at all.

Mr. O'Farrell—It is surprising that he did not call on Dr. Ryan, who was so near him.

Mr. Cullen—Is he not bound to call on a doctor in this Union, if convenient for him to do so, before any other?

Mr. O'Farrell—If the board will act wisely they will make an order to that effect.

The matter dropped.

ABOLISHMENT OF WORKHOUSES.

THE following resolution has been adopted by the Middleton Union, and sent for adoption to every board of guardians in Ireland:—

"That this board is of opinion that the time has arrived when workhouses throughout Ireland may be, with much advantage both to the ratepayers and those few persons

legitimately entitled to relief, abolished, and, amongst others, for the following reasons:—

"1. This house was originally intended to accommodate one thousand persons. The paraphernalia and staff inclusive still continue sufficient for the wants of that number, whilst in reality there are only about two hundred and fifty, all told, in the establishment, and of these one hundred are capable of earning a livelihood outside the house, the remaining one hundred and fifty costing the ratepayers £9,000 per annum, of which sum the management, with its surroundings and abuses, appropriates about £7,000.

"2. The system has a demoralising effect on those who avail of it, and tends to dry up those sources from which charity—spontaneous charity—should, and undoubtedly would, follow, and which, in addition to a slender grant from the State, as in most countries, would be sufficient to maintain in a suitable manner all fit subjects for relief.

"3. The poorhouse and other buildings in connection therewith, the property of the ratepayers, could be utilised by boards similarly constituted, as, for instance, those in all Her Majesty's Colonies, for like purposes.

"And, further, that in the event of there being any doubt as to the efficacy of the change prayed for, this board would earnestly court a full inquiry in connection with the matter, feeling sure that such a case could be made out as would cause the total abolition of a system that has contributed largely in bringing the country to its present state of misery and degradation; and that a copy of this resolution be sent to Mr. Gladstone, the boards of guardians throughout Ireland, as well as to the leader of the active Irish party, with the request that that gentleman would bring the subject on an early day under the notice of the House."

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

(Continued).

Mr. HENRY ROBINSON'S examination continued.

435. In effect, does not your knowledge of the inefficiency or efficiency of the officer depend upon the receiving a bad or good report of him?—Yes, our inspectors report every half-year upon him.

437. Take the case where the board of guardians are cognisant of a medical officer not discharging his duties in a perfunctory manner, but discharging them with a great deal of professional skill, do you consider it reasonable that a board of gentlemen sitting in Dublin should

control the actions of guardians who would award to that man a superannuation equivalent to the estimation in which they held his performance of the duties?—I do not think that there is any other way of meeting the difficulty besides giving us that power. I am not aware of any other way of doing it. We only desire it in the interests of the officers, and if we are not given the power we are content to be without it. It is for Parliament to decide whether we shall have it or not.

438. Mr. Justin M. Carthy. You give us, as the main reason for this Bill, that in so many cases the boards of guardians refused to pension officers?—Yes; and that officers, in consequence of that, remain in office too long.

445. It does not at all follow that the guardians were wrong in some of these cases; you are perfectly aware that the whole question of pensions to servants is one very much debated, and that in many unions, as you told us yourself, pensions are refused because they do not approve of the principle?—Yes.

446. Are you aware that in the vast majority of civil employments there is no superannuation, and no pension?—Under the Civil Service.

447. I mean civil appointments?—In the vast majority I believe it is so.

448. Would not it be perfectly possible to get valuable servants under the Poor-law Board as well as in ordinary civil life, without pension?—You will have much more valuable servants if you allow them pensions. I do not mean to say that up to the year 1865 valuable servants were not obtained; but I think that you will obtain a much better class of officers.

455. That is another class of cases. There are some of these cases where you have not made investigation into the actual merits of the officers. You merely assumed that as the officer was there, he must have been a good officer?—We assume that if the officer were there, and his conduct not reported unfavourably, he must have been sufficiently good to entitle him to a pension.

461. Do you really think that a board of that kind, sitting in Dublin, a central board meeting in private, could more satisfactorily settle for all these questions than the board of guardians elected by the public of 163 unions?—I think so.

513. Mr. Healy. Take the case of a man of 60 years of age, and say that he can get a local position under the Government in the Post Office, or in the town clerks' office, or from a grand jury, or something of that kind, you enact that this man shall never earn more than the total amount of his pension?—That is taken exactly from the Civil Service practice.

514. No man in his senses would accept extra office in that case, because he would be only entailing additional work upon himself, seeing that he could gain nothing by taking additional office. Having his pension no one would take additional office simply for the fun of the thing?—He might receive an appointment of a higher value than his former one, and then his pension would cease.

515. Is it not putting a premium upon enforced idleness?—No, it is advisable that a man should not be receiving a pension from the ratepayers, and, at the same time be earning sufficient to keep him; if he is able to get an appointment, while he acts and performs the duties of that appointment, I do not see that the rates should be made chargeable with the whole of his pension.

533. Mr. Biggar. As to the question of practical routine, if I understand aright, if an official is dismissed he is ineligible for future employment under the Poor Law Board, and he is also disqualified from getting a pension?—He is disqualified from holding office again under the Local Government Board unless the Local Government Board specially gives sanction; the board

of guardians could not appoint him again without our sanction, but we have power to sanction the re-appointment of an officer though he has been dismissed.

534. What occurs in practice is that an officer as a rule retires rather than run the risk of having a formal dismissal; is not that the ordinary routine?—Yes.

535. The usual routine is that an officer who is likely to be dismissed retires?—Yes; it very often happens, unless the case is a very gross one, that we say to the guardians, You can call upon so-and-so to go and give him an option, mentioning that if he does not resign he will be dismissed, and generally the officer does resign.

536. Then dismissals seldom take place?—They do take place, if the case was one which it is necessary to make an example of. If an officer showed an unwillingness to resign we should dismiss him.

537. It is very rare?—I cannot say that it is very rare.

538. Is there once a year, upon the average, a case of dismissal?—More than that.

DR. ARCHIBALD HAMILTON JACOB, *examined.*

539. You are a member, are you not, of the medical profession in Ireland?—I am.

540. Are you connected in any official capacity with the Irish Medical Association?—I am a member of the executive committee of the Irish Medical Association.

541. Are you of opinion that a change is necessary in the law affecting the superannuation of poor law union officers in Ireland?—I am very strongly of that opinion.

542. Will you state to the Committee the main grounds of your opinion?—The main ground upon which I base the opinion is that great injustice has resulted to the union officers themselves, and, as I take it, great injury to the public service from the present condition of affairs. Firstly, that the union officers are compelled to remain in harness long after they have ceased to be capable of efficiently discharging the duty, and thereby the service of the public is injured. A union officer is debarred from resigning because, according to the rule, a month must elapse between the period of his resignation and the period of the consideration of his superannuation allowance; and, in consequence, he must necessarily resign without having a perfect knowledge of the intentions of his board of guardians, and within a month those intentions frequently develop in a direction contrary to what he expected, and he finds himself without a pension and without office. The result of the discretion vested in the board of guardians is, that a great number of union officers hold on to their offices long after they have ceased to be competent efficiently to discharge their duty.

543. You are personally acquainted, are you not, with medical officers who are holding on to their offices under those conditions?—With a very large number of them.

544. Sir Patrick O'Brien. Are there a dozen?—Yes, and very many more.

545. Chairman. Would you give the Committee some of the instances?—As to the number who are so holding on, I have certain means of calculation. I find that the average age of retirement of those who have retired is 66.5 years. Taking that as the age at which an officer may reasonably be expected to retire from old age, I have looked into the lists of the poor law medical officers with the view of ascertaining what numbers of them have reached that age, but have not retired. Of course I have no means of knowing exactly the age of the poor law medical officers.

546. You think that 66.5 is the average age of the retirement of union medical officers?—Yes, I am speaking entirely of union medical officers. I am not pre-

pared to speak on this question with regard to any others. Not having absolute means of judging of the ages of the poor law medical officers, I have taken the best means that I have available, namely, by examining the date at which each medical officer received his qualification to practise medicine. No man is allowed to qualify as a medical man under 21, and therefore every man who received his qualification 45 years ago, i.e., prior to 1838, must be at least 66 years of age. Thus I find that there are 71 medical officers who must necessarily be above 66 years of age. All these would be entitled to pensions, besides other medical officers who being under that age may be incapacitated by ill-health.

547. What is the total number of union medical officers?—The total number of union medical officers, including workhouse medical officers, is about 1,000. I am speaking now of medical officers only.

548. Mr. Daly. That is including dispensary physicians, and resident medical officers?—Just so. I have spoken of the number of persons who probably are above the statutory retirement age, if I may so phrase it, but as to individual cases I have a record of many officers that have long passed that age, and who are still in the supposed discharge of their duties. I have a few cases noted here. The first is the case of a gentleman who is aged 82; almost all the cases that I have referred to are those of dispensary doctors, and this gentleman is a dispensary doctor; the limit of his district is seven miles from his residence, and he may have 14 miles to travel to visit a case. In another case in the same district the officer's age is 69, the officer being very infirm, district 2,300 acres, population 7,000. Another gentleman is aged 66, with 30 years' service, and he has a bad heart disease, as certified by Sir Dominic Corrigan and various other physicians of the highest name, who have testified that the discharge of his duties is dangerous to life; that was certified in 1878, and he has continued to do the duty for four years since then. In the fourth case the age is 73, 40 years' service, and very infirm. In the fifth case the age is 79, with 50 years' service; the officer has varicose veins in both legs, from standing and walking, and has impaired sight, hernia, partial blindness, and bad bronchitis. In the sixth case the age is 70, with 40 years' service; that officer has chronic inflammation of the bladder, and cannot work. In the seventh case the age is 70, and he is always ill with bronchitis; I have not his length of service. In the next case the age is 80, with long service; and there are no details as to the state of health. In the ninth case the officer was 78 years of age, with 40 years' service; and perhaps I may be allowed to describe this gentleman's case in a few words, as I happened to receive it from my correspondent. "He worked on with a gradually increasing disease of the heart until within a few months of his death; during the last two years of his life he was known to go out day after day visiting over this immense district of country with his limbs swelled by dropsy, and on one occasion he tried to attend a poor woman in dangerous labour, but the house was situated across a bog on the face of a hill so difficult to approach that by reason of breathlessness he was unable to reach it, and had to turn back almost in a dying state with the exertion, and then send for and pay a substitute. Well, the time came when he could not even ascend his dispensary stairs, his breathing become so laborious, and he is seized with increased dropsy, and is at last confined to that room from which he is destined never to go until carried to his long home." That gentleman is dead. I have two other cases, one of a gentleman aged 81, who served 43 years. This gentleman is also dead. He did not apply for superannuation, because he knew there was no chance. My information is that for the last five years he was disabled by chronic gout, and had

to be lifted into and out of his vehicle. The guardians would neither pension him nor pay a substitute, and they forced his son (who himself had a large district in the neighbourhood to attend to) to do all the work of the father's district gratis, which he managed to do in order to save his family from the workhouse. The last case that I have to mention was one in which the officer had 25 years' service, and he was unanimously recommended by his dispensary committee for a pension, and four times brought before the board of guardians, who refused it; and he died starving four months afterwards. These are a few cases that I thought well to lay before the Committee.

549. Chairman. In the case that you last mentioned, had he retired?—Yes, he had retired; but he was not pensioned, although four times recommended to the guardians by his own dispensary committee.

550. I presume that the duties of these dispensary officers are very arduous?—Very much so; they have, some of them, very large districts; it not being an unusual thing for a man to have to travel seven or eight miles either way to attend a case. He is bound to be at the disposal of patients at all hours of the day and night, and much of his duty is in the middle of the night, where he has to follow labour cases for considerable distances in all weathers.

551. Mr. Meldon. So that, in fact, although he may not every moment be occupied by his duty, he is bound to be at his duty whenever called upon?—Quite so, exclusive of every other business whatsoever.

552. Chairman. Have you reason to believe that, where no application for pension was made by the medical officers whose cases you have been stating to the Committee, they held on, because there was no certainty that if they retired they would receive pensions?—I have; for I know that there are many medical officers now existent who would apply to-morrow, or would have applied years ago, if they thought that there was the remotest chance of their getting a pension.

553. Those gentlemen whose cases you have mentioned, you feel sure would resign if they had a reasonable prospect of receiving a fair pension?—Yes, every gentleman who had arrived at a condition of incapacity would retire; but I do not anticipate that there would be much retirement in the case of medical men earlier than that, because there are a variety of reasons other than the difficulty of getting a pension for keeping them from retirement. They must, if they retire, introduce into their district a rival practitioner; and, therefore, as a general rule medical men will not seek superannuation until it is entirely impossible for them any longer to do their duty with satisfaction.

554. You think that if this Bill passes into law medical officers would not rush to avail themselves of its provisions?—I am sure that none would apply except those who felt themselves incapable of discharging their duties.

555. Have there been any cases to your knowledge in which pensions have been granted to medical officers after they have served very short periods on comparatively insufficient grounds?—I made, from Mr. Meldon's return, a little analysis of a certain number of cases in which pensions have been granted, and a similar number of cases in which they have been refused. I do not mean to express the opinion that those who were retired at an earlier age were retired without good reason, for I have not any knowledge of the reasons, but I find here 12 cases of medical officers who were granted pensions retiring at the average age of 44·3 years, while 12 others were refused, although they had arrived at an average age of 62·5 years; that is very nearly 20 years older. Of those to whom the pensions were granted the average length of service was 12½ years, while of those 12 to whom pensions were refused

the average service was 32 years; that is to say, those who were refused had served 20 years longer than those who were granted pensions in those particular cases.

556. If a medical officer discharges his duties with conscientious strictness, do you think that he is in any danger of rendering himself unpopular to his guardians?—I think that there is very considerable danger, especially in connection with the discharge of his duties as a sanitary officer, which bring him necessarily into unpleasant contact with the owners of small property who may probably be influential with the boards of guardians.

557. Then you think that it would be advisable to place a medical officer above the consideration, that if he does his duty with strictness he may offend his board of guardians, and not receive a pension?—I think that it is very highly desirable.

558. Mr. Solicitor General for Ireland. You mention the average age of retirement as 66·5; that arises from assuming the minimum age at which qualifications were obtained in each case?—No; 66·5 is certainly the age, because it is derived from the table published by the Local Government Board of the persons who have actually been superannuated. The other calculation is on the ground of the age of persons who have not yet been superannuated, but who have passed the statutory age, and might be retired to-morrow, and who, probably, are unfit for duty.

559. In your calculation there must be at least 71 who are above that age?—Yes, above 66, certainly.

560. Is that an ascertained figure, or may there be more than 71 who are over that age?—There may be very many more.

561. It depends upon the age at which the officer obtained his medical qualification?—Quite so, and I have taken the minimum age of qualification. Many men qualify over 21, but I have taken the minimum age, and there cannot be less than 71 persons.

562. Mr. Gibson. Have you reason to know from personal intercourse that many of those 71 gentlemen who, as you say, must be over 66 years of age, would retire if there were some machinery by which they felt sure that they could get some pension?—Yes, I have the best reason to know that that is so from constant intercourse with those gentlemen.

563. And that the majority would be willing to resign?—Yes; all of them who are incapable of working dispensary districts.

564. Do you know any of them that are willing so to retire who have applied for pensions and have been refused?—No, because an application for a pension involves resignation.

565. So that they must go as it were with their commission in their hands?—Quite so. They would cease to be dispensary officers if they made an application whether they were pensioned or not.

566. They have to feel their way beforehand as well as they can, and if they find that there is no chance of their getting a pension they retain their position?—Yes, that has been the universal practice.

567. You said that the discharge of their duties as sanitary officers was likely to make them unpopular; have you reason to know that from personal communication with the medical gentlemen who have been acting in that capacity?—Yes, I have.

568. Are you also aware that in some districts the relieving officers give with rather a lavish hand what are called "scarlet runners;" that is to say, they give to farmers, who can very well afford to pay for medical advice, a ticket that entitles them to get the assistance of a medical officer for nothing?—I am aware that that is a practice very widely spread over Ireland, but not by any means confined to relieving officers, who are the persons least erring in that respect, but it is done by members of dispensary committees and wardens. The relieving officers in Ireland are not at all the persons most liable to do that.

The abuse of the system of medical relief is generally at the hands of committee men and wardens, who are very much more numerous than relieving officers.

569. Do you know of the practice prevailing in many parts of Ireland to give tickets to farmers and to others whose pecuniary position would enable them to pay for their medical attendance?—Yes, there are districts in Ireland in which private practice is almost *nil* in consequence of the population being mainly composed of cottier farmers, and those being all in the medical relief list.

570. And a medical officer, practically, is bound to obey one of those orders when he gets it, no matter if it was given to a person who might be supposed by his rank and position to have private means?—He is absolutely bound to attend any case for which he receives a visiting ticket, no matter who the person may be, so long as the visiting ticket is legally drawn out.

571. If a medical officer remonstrated, that would be another circumstance which would make him somewhat unpopular with the guardians against whom he remonstrated?—Quite so; especially as his remonstrance can only be carried into effect by application to the dispensary committee to cancel the ticket, which therefore must be a public remonstrance, and he brings it, as it were, before the tribunal in which the case has to be fought out as between the doctor and the person whose ticket he challenges.

572. You would then give us a further instance of the possible unpopularity which had been incurred by the medical officer in addition to the performance of his sanitary duty, the duty which he might sometimes feel called upon to exercise, of remonstrating against the distribution of those tickets?—Certainly.

573. Mr. Meldon. The interests of the medical officers of health are protected by the Irish Medical Officers' Association, are they not?—The interests of the medical officers of health are included within the scope of the Irish Medical Officers' Association operations.

574. But the Irish Medical Association protects the interests of the general body of Irish medical officers?—Entirely.

575. Under the existing law the boards of guardians have got power to grant a superannuation not exceeding two-thirds of the salary, quite irrespective of the number of years' service, or otherwise?—That is so.

576. Do you happen to know whether the Irish Medical Association considered the question of foregoing the right to two-thirds of the pension in consideration of the certainty of getting a pension?—That question has been very recently considered not only by the executive of the Irish Medical Association, but at successive general meetings; and it has been conclusively determined as the policy of the Association that they are willing to forego the possible grant of two-thirds after a short period of service, in order to obtain security for the grant of a moderate pension at the proper period of service.

577. Have they then adopted the proposed scale of the Civil Service superannuation, in consideration of its being obligatory upon the guardians to grant superannuation?—Quite so; that is their view.

578. You referred to some cases where medical officers had continued to serve because they could not get pensions; can you refer to any striking cases where medical officers have applied for superannuation and have been refused, besides those which you have mentioned?—Yes; I have just a brief note of six cases. One a gentleman of 42 years' service, 76 years of age, refused; the second one, a gentleman of 25 years' service, 56 years of age, granted, but then withdrawn when it was found to be a district charge.

579. Sir Patrick O'Brien. How was that; can you explain that?—When it was found that the pension would lie on a particularly narrow district, the guardians went back from their original determination.

(To be continued.)

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

REPORT ON THE INCORPORATION OF THE IRISH MEDICAL ASSOCIATION, READ AND ADOPTED AT THE SPECIAL GENERAL MEETING OF THE ASSOCIATION.

Held in pursuance of the requirements of the Board of Trade, at the Royal College of Surgeons, Dublin, on the 31st day of October, 1882.

DR. ROBERT BROWNE (Chairman of Council) in the Chair.

MR. CHAIRMAN AND GENTLEMEN,—During many years, and almost ever since the foundation of the Irish Medical Association in 1839, considerable inconvenience has, from time to time, been felt in consequence of the Association not being incorporated; but, as that desirable step necessarily entailed heavy expense, it was deferred until the funds of the Association were in a prosperous condition, and that condition, the Council are gratified to be able to state, has been recently attained.

Ever since incorporation of this Association was first recommended by the Council, the Annual General Meeting of the Association, at each successive gathering during several years, adopted the following resolution, viz. :—

“That the Irish Medical Association be formed into an Incorporated Company, limited by guarantee, but without the addition of the word ‘limited’ to its name (such guarantee not to exceed the sum of five shillings); and for that purpose an association, bearing the same name, shall be formed, registered, and incorporated, under the Companies’ Acts of 1862 and 1867, limited by such guarantee as aforesaid, and without the addition of the word ‘limited’ to its name, and the present Association be amalgamated therewith; and that the Council of this present Association are hereby empowered and requested to do and take all the steps requisite for carrying this resolution into full effect.”

The Council, however, did not consider that the financial condition of the Association justified them in incurring so heavy an expense earlier, but now they have much pleasure in informing the members that this Association has, within the past few months, obtained the required sanction of the Board of Trade, and that it is now registered as an “incorporated society,” under the Acts of Parliament, under the style and title of “The Irish Medical Association,” without the addition of the word “limited.” The advantage of limitation of responsibility, however, is secured to its members, whose personal liability is limited to the insignificant sum of five shillings each, as the only claim which can possibly be made against any of them on behalf of the

Association beyond the amount of the annual subscription.

Before the Association was incorporated, any individual member could have been sued at law for the entire amount of the debts (if any) of the Association.

In 1874 the Association nearly collapsed in consequence of the very large amount of its debts, and it was then felt that the liability for all its debts which attached to each or any specially selected member was most prejudicial to its success, as it deterred many from joining; fortunately, however, by most strenuous efforts, the Association was soon tided over its difficulties, and a new era of prosperity and greater usefulness was entered upon.

The Association is now in a flourishing condition, with ample funds in hands to meet any expenses which it may be deemed in the interest of the Association to incur, and it stands this day without any debts or liabilities whatever, further than the current expenses of management.

The formalities required to be gone through before the incorporation could be effected necessarily occupied much time, but your Council so arranged the matter that the required dissolution of the Association was not permitted to take place until the very moment it came again into existence as an incorporated body, and thus the Association and its operations continued without the least interruption.

On a memorable occasion, when the Public Health (Ireland) Bill, 1877, was before Parliament, the Council of the Association, on behalf of the dispensary medical officers, whom it was proposed should be compulsorily obliged to be the medical sanitary officers of their respective districts, petitioned Parliament strongly against the Bill, inasmuch as it did not reasonably respect the position and interests of medical officers, define suitable and strictly professional duties to them, nor guarantee that their services would be fairly remunerated, nor yet adequately provide for the due protection of public health.

The petition of the Council was so strongly opposed to the terms of the petition on the same Bill which had been sent forward by the Corporation of Dublin City, that that body forthwith denounced the Irish Medical Association as “as an unknown body, comprising only a few dispensing medical attendants;” and the Council representing an unincorporated Association had no *locus standi* before Parliament to refute the base calumny.

Hitherto, all petitions to Parliament forwarded by the Council on behalf of the Association were (owing to the Rules of Parliament) held to represent the views only of the individuals whose names were attached; and as time seldom permitted the Council to obtain more than a few signatures, the petitions had not the great weight

which all future petitions, bearing the signatures of the President and Hon. Secretary, and the seal of the Association as an incorporated body, will have.

Henceforth, a petition to Parliament can be perfected in a few hours, and will have the same weight as if signed by every individual member of the Association.

As an incorporated body, the Irish Medical Association will in future have the right to petition Parliament as an Association representing several hundred members, whereas formerly any petition in the name of the Association was received only as a matter of courtesy, and held only to be that of the signatories as private individuals.

The right to sue and be sued at law as a corporate body also attaches to the Association now, which enables the Association to recover at law all debts and liabilities to which it is entitled, and, as before mentioned, renders the Association itself, instead of any individual member, liable for any debts which may hereafter be incurred by it—a condition which, whilst affording due protection especially to the most prominent members of the Association, and removing reasonable grounds for anyone objecting to take an active part in its working, at the same time will not induce the Executive of the Association to depart from strict observance of the rules, and their duty not to render the Association at any time liable for any debts over and above the amount of the funds in the hon. treasurer's hands, an account of which is given every quarter, or as often as requested.

The Council begs most warmly to congratulate the members upon the completion of the incorporation of the Association, the highly prosperous condition of its finances, and the active progress of its work, feeling confident that the position which the Association has now attained will render it capable of even more effectively advancing its objects and the interests of its members.

Strong as is the position of the Association at present, it can, and ought to, be greatly further strengthened by the addition to its list of members of the names of a very large number of medical practitioners who up to the present have not joined, very many of whom, though holding public appointments, and especially Poor Law appointments, have never contributed to the funds of the Association, although solely in consequence of its exertions their incomes have been considerably increased, and their positions vastly improved.

As the great advantages already derived and derivable from the efforts of the Irish Medical Association are most tangibly felt by members of the profession who hold public appointments, and especially by those connected with the Poor Law Service, the Council hope that they may not again have occasion to complain of want of support from anyone who reaps the benefit of those exertions, and they trust that every member of the profession connected with the public service will at once see that it is his own personal interest to join the Association, and remove from connection with his name the slur of accepting pecuniary and other advantages towards the expense of attainment of which he has not contributed.

By order of the Council,

JOHN H. CHAPMAN, Hon. Secretary.

60 Pembroke Road, Dublin.

OWING to the death of Dr. Burrowes, Coroner for Sligo, a vacancy exists in the office. There are two candidates in the field—Dr. Roe, of Carney, and Dr. Molony, of Collooney.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

(Continued).

Dr. JACOB's examination continued.

580. And his resignation was in and it was accepted?—Yes. The third case is that of a gentleman of 48 years' service, aged 74, refused. In the fourth case the gentleman had 32 years' service, he was 60 years of age, and refused on the ground of economy. The fifth case was one of 26 years' service, and aged between 50 and 60, refused on the ground that the board would grant no superannuation; and the last case is that of a gentleman of 30 years' service, aged 72, who was refused for the same reason. The average period of service of those gentlemen was 34 years, and their average age was 66½.

581. Mr. Meldon. In Ireland, I believe, the medical officers are dependent upon their salaries and their remuneration as medical officers for their entire professional income?—In the poor districts it is entirely so; the emolument which it is possible to earn from private practice in many districts in Ireland does not go beyond £50 or £60 a year at the utmost.

582. Can you state what is the average age at which medical men join the Poor-law service?—I should say from 26 to 29.

583. Is there any minimum age?—The minimum age is 23; they cannot get in unless they are 23. As a general rule men join as soon as they can get a dispensary, after they are 23, and it takes them as a general rule about three years' waiting, that will bring them to 26 or 27 years of age.

584. Colonel Tottenham. Where pensions have been granted what has been the usual applotment of the pension; has it been over the union or over the dispensary district that the charge has been made?—I am not able to answer that question satisfactorily.

585. In some cases I believe it has been done upon the union and in some upon the dispensary districts?—So far as I know it is a question of rule; boards of guardians have no power to put it on the district, or to put it on the union.

586. Is there a rule governing it?—I believe there is, but I cannot quote it.

587. You cannot tell whether the rule is to lay it over the union, or over the dispensary district?—No, I cannot give evidence upon that point.

588. Mr. Biggar. You told us about a medical officer aged 82, whose son did the work for him; with regard to that gentleman is it not the case that the usual custom is that when doctors are ill, or on leave of absence, a substitute is appointed for a limited time, the expense being paid by the guardians, and at the same time the full salary goes on to the doctor?—According to the 23rd rule for the management of dispensaries, a medical officer becoming ill has simply to notify the fact of his incapacity to do the duty to the secretary of the dispensaries, and to recommend a duly qualified person to do it, and in that case the dispensary committee deals with the person so recommended; and if the person so nominated does the duty, the board of guardians may, or may not, pay him. In some instances they have refused to pay him; but the medical officer is not legally bound to pay the substitute under those circumstances. In practice, however, the system does not so work. The medical men in all districts when they get sick must care for the lives and healths of their patients, and they run off and make a private bargain with somebody to act as their substitute, and that person they recommend to the dispensary committee, who may, or may not, accept the recommendation, and may, or may not, appoint the man; but whenever that man is not

paid by the board of guardians subsequently, there is a moral obligation on the sick medical officer to see to his payment. Nevertheless, strictly speaking, what you state is correct, the board of guardians is bound to pay if they make an arrangement with the substitute to that effect.

589. In the alternative case that you put, it amounts, practically, to giving a temporary pension to the medical officer; that is to say, he probably makes a bargain with his substitute at a less rate than he himself receives?—No, as a general rule it is the other way; he often has to pay more money than he receives, because a substitute, taking the duty for a very limited period, expects to be better remunerated than the medical officer who takes it for an extended period.

590. You referred to the case of a gentleman whose son did the work for him; of course the full salary was paid?—Yes, I believe the full salary was paid to the sick medical officer, but the substitute was not paid by the guardians, and did the work for nothing, because the sick officer was his father.

591. So that it was all in the family?—In a certain sense it was; my note is "last five years disabled by chronic gout; had to be lifted into and out of his vehicle; guardians would neither pension him nor pay a substitute, and forced his son (who himself had a large district in the neighbourhood to attend to) to do all the work of the father's district gratis, which he managed to do, in order to save his family from the workhouse."

592. Dispensary tickets to parties who are unable to pay the full legal fare of a guinea, by which they are able to pay a small fee of 5s. or 7s. 6d.?—It is utterly contrary to rule for a dispensary medical officer to receive a sixpence of any sort from a patient for whom he receives a dispensary ticket, and if there be any case such as you speak of it is an infraction of the rule, and I believe it to be very exceptional.

593. It would not be an infraction of the rule; a dispensary doctor might recommend to the committee that a person who was not entitled to gratuitous relief was able to pay not the full fee, but the reduced fee?—He could not receive a fee until the ticket had become null and void by being cancelled by the dispensary committee. A man must cease to be a dispensary patient before the doctor can accept a sixpence from him of any sort.

594. In the case you have mentioned of the doctor aged 81, whose son did his work for him, have you told us all the facts candidly?—Entirely so, I believe.

595. Would you be surprised to hear that the facts are not correctly stated?—Necessarily the information which I have given the Committee has been derived from persons on the spot; and it cannot be of my own personal knowledge, but I have complete confidence in the accuracy of the gentlemen who have given me this information. The statements of the cases in which there has been great hardship came from a large number of places in Ireland, and then an inquiry further to develop the facts was made from the persons who originally gave the information.

596. Is it the common custom with doctors in Ireland, irrespective of their dispensary work, that if a person does not get attended through a dispensary ticket he would have to pay a guinea for each visit?—Certainly not for each visit. A guinea per visit is the rarest thing possible in the provinces in Ireland. Many medical men will not receive less than £1, but then they attend five or six times for the £1, and there are a great number of medical men who receive 10s. or even less for the first visit; but they do not hold themselves bound to attend more than once or twice for it.

597. You raised a point with regard to sanitary officers; is it the custom in the large towns for the dispensary doctor to be the sanitary officer?—The dispensary doctor is the medical officer of health *ipso facto*. In the urban districts, such as Dublin and Cork, and Belfast, there is also a superintendent, and he is the head over the system; and there the dispensary doctors are medical officers

of health under him; and all through Ireland the dispensary doctors are *ipso facto* medical officers of health.

598. Excepting in large towns?—And even in large towns.

599. In the urban districts do the dispensary doctors get a salary as sanitary inspectors from the boards of guardians?—Yes, they get a small salary; and in addition, in urban districts, there is a superintending officer who gets a larger salary.

600. Is he under the control of the town council?—He is under the control of the guardians in every case in which the guardians are the sanitary authority; but in places where the town commissioners are the sanitary authority, as in many urban districts, he is the town commissioners' officer.

601. But he is paid by the guardians all the same?—He is paid out of the rates.

602. Then he is more or less dependent upon them for his pension?—Yes. According to the present law a medical officer does not receive any pension in respect of his sanitary salary, because the law which made him medical officer of health passed at a date subsequent to that law which gave him superannuation, and therefore he is excluded from receiving a pension in respect of his sanitary salary; but under the Bill now before the Committee it is proposed that sanitary salaries shall be included as a part of his emoluments.

603. Mr. Robinson named several grades of salary which a dispensary doctor gets, and several grades of emoluments. First of all can you tell us what they are?—He has his salary as a dispensary medical officer, or *mutatis mutandis*, if he is a workhouse medical officer.

604. He is not necessarily a dispensary medical officer if he is a workhouse medical officer?—No, but he has his salary as a dispensary doctor in the union; he gets the vaccination fees, and he has the fees for the registration of births, deaths, and marriages, and he has the emolument as a medical officer of health, and he has one or two subsidiary things; for instance, he has the fees for the certifying of dangerous lunatics; and occasionally he has fees for giving evidence in sanitary prosecutions, those being little matters of a guinea here and there.

605. Could you give me an estimate of what the salary would be for a dispensary doctor?—I think the average salary of all the dispensary doctors in Ireland is about £102.

606. That is the salary alone?—Yes, the salary alone, I think, is about that.

607. About what would the dispensary doctor earn with his vaccination fees?—Of course they vary enormously, because in large metropolitan districts the vaccination fees are very valuable, whereas, in country districts sometimes they are almost nil, but I should say, all round, from £6 to £8 a year would be the average.

608. And the same argument, I suppose, would apply to the registration fees?—Yes, the same argument would apply to them, with this difference: I think the registration fees would not probably be as high as those for vaccination; they would not amount to £8 a year on the average.

609. What does he get as medical officer of health?—Varying from £5 up to £15. I should say that £10 would be a fair average.

610. Then what are his fees for certifying lunatics?—That would be a couple of guineas a year, perhaps.

611. And what are the fees for sanitary prosecutions?—On the average, probably, about a couple of guineas a year. In a great many districts there is never such a thing as a sanitary prosecution.

612. That would make £125 on the average?—Yes, about that.

613. Is it not the case that in a country dispensary district it is indispensable for a doctor to keep a horse?—Perfectly indispensable.

614. In the case of superannuation would the expense of the horse be taken off his gross income?—It is not con-

templated that it should be taken off his gross income. It is a portion of his household expenditure as much as milk or any other necessary of life is.

615. Of course he cannot live without household expenses, but if he were retired on a pension would he require to keep a horse?—It would depend upon the nature of his district whether he would or not.

616. Of course, when practising in a country district, and he had to move about from place to place he would require some means of conveyance; he must either hire a machine, or drive; that is certainly not a personal expense, but a trade expense?—I do not anticipate that a man when he retired would remain in the house for ever; he would require to go out to a limited degree for a short distance, although, perhaps, not to say any great extent.

617. Do you mean to tell me that a retired dispensary doctor who would have £129 a year would require to keep a horse for his own personal use, supposing he retired from practice?—No, I think he would not, taking the average of cases.

618. Do you think that in that case the expense of a horse should be taken off the gross income, supposing it came to be a question of what his net income should be. Of course you know that it is proposed to estimate the lodging money and the rations of the other officers of the poor law?—Yes, I do; but I do not think any deduction from gross income should be made.

619. And where there are special expenses, do you think it is legitimate that those unavoidable expenses should be taken off the gross income?—I would not think it at all equitable that the expense of a horse should be taken off the gross income, for I look upon a horse in a country district as almost a necessity, irrespective of a man's public duty.

620. Do you mean to tell me that a man living privately with only £129 a year would keep a horse for his own private use?—I think most men in the position of retired medical officers would require to keep a horse in a country district.

621. Would he require to live in a country district at all?—No, he would not require to live in a country district, he might go anywhere he liked.

622. I am supposing that there are no unavoidable drawbacks that keep him all the time in his lodgings; but is it not the case that in large registration districts, such as Belfast, the registration is done by proxy?—I cannot answer for Belfast, but it is very unusual in Ireland, and if it exists at Belfast it does not exist much elsewhere.

623. Supposing that it did exist, would you think it legitimate that the money paid to the proxy should be taken off the gross income?—I presume that in a case where a proxy is employed the proxy would be paid by the medical man.

624. Then, of course, the balance or the net profit belongs to the dispensary doctor?—Yes.

625. And, of course, he would only have a right to pay the balance; he would be only entitled to get a pension based upon the balance?—Yes, I think the balance would be only his emolument. As a matter of fact the dispensary officers throughout Ireland have the refusal of the registrations except in a case where the dispensary doctor is already in office. When a medical officer is appointed to a district, he has a right to have the appointment, if he pleases, and in 99 cases out of every hundred he does have the appointment. The Registrar-General puts every pressure upon him to make him take the appointment, and the consequence is that cases in which proxies exist are extremely rare. If they exist in Belfast (and I was not aware of the fact), it must be about the only place where they do exist.

626. Mr. Healy. Do you hold any office under the Local Government Board?—No; I never was a poor law medical officer; but from the position which I have held

for a number of years of Editor of the *Medical Press and Circular*, I have most intimate communications with the poor-law medical officers over the country for 20 and odd years.

627. Are you secretary to the Irish Medical Association?—I am not secretary; I am on the executive committee.

628. How long have you held that office?—I have been a member of the executive committee 15 or 16 years.

629. When was the Association formed?—It was formed in the year 1839, and it was reconstructed in the year 1853.

630. How often does the executive of the Medical Association meet?—Every week.

631. Then may I say that you look very vigilantly after the interests of the medical profession?—We do so as closely as we possibly can.

632. You are aware that at the time when the medical charities were instituted, the salaries and emoluments of the medical profession out of the rates were much lower than they are now?—I am aware of that.

633. And I think I may say that it is to the credit of the Irish Medical Association that an increase of leverage has been obtained, by which a gradual increase in the salaries and emoluments of the doctors has been made general?—The Irish Medical Association deserves credit for having availed itself of the natural advance in emoluments and the natural advance in the cost of living, and they have availed themselves of those facts to bring them before the notice of the boards of guardians; but the growth of salaries, I take it, has been in consequence of the growth of the expenditure required by a medical officer to do his duty.

634. But it is the fact that when the medical officers were attached to the union at first they got no salary whatever for the great many minor sources of emolument which you have just mentioned to my honourable friend, the Member for Cavan?—They always received a salary, but many of the minor sources of emolument did not exist.

635. Did they originally get the vaccination fees?—Only since the passing of the Compulsory Vaccination Act.

636. The same thing, of course, applies to the registration fees, the Act for which was passed about 1863?—Yes.

637. Did they originally get the salaries of the medical officers of health?—Since 1878; that was the date of the passing of the Public Health Act; according as each Act was passed those emoluments accrued.

638. Did they originally get the emolument for the certification of dangerous lunatics?—No, only for the last six or seven years.

639. How was that obtained for them?—The original Act was passed in 1867, obliging medical officers to certify for nothing, and then in a subsequent Act, passed in the year 1875, a clause was inserted giving them the emoluments, subject to the approval of the magistrates, who would certify to that effect. In the case of dangerous lunatics, but not any other lunatics, they are necessarily brought before the magistrates with a view to their committal by the police.

640. With regard to giving evidence in sanitary prosecutions, when was that charge granted them?—From the date of the Public Health Act, which, I think, was 1878.

641. Therefore, in point of fact, the whole average salary of the medical officers originally was about £100 per annum, and they have since then, in emoluments, got a gradual addition out of the rates of about £30 per annum?—Yes; by those emoluments they have acquired an additional income of somewhere about that.

642. I suppose in the origination of those Acts of Parliament your Association has had considerable influence?—Yes, we have done our best in those cases.

(To be continued.)

IRISH POOR-LAW INTELLIGENCE.

THE HEALTH OF DUBLIN.

FROM the report on the state of public health in Dublin during September, issued by Dr. Cameron, we learn that the deaths within the Metropolitan Registration Area during September were in the ratio of 25·02 per 1,000 persons living.

The deaths within the Municipal Area, or City, were in the annual ratio of 27·3.

The deaths from the seven principal zymotics were, in the whole district, in the ratio of 3·32. In the city, 3·48.

As compared with the preceding month, there was a decrease in the fatal cases of typhoid fever and of diarrhoea and dysentery. There were 7 deaths from typhus as compared with 5 in the previous month. With respect to the other zymotic diseases, they caused very few deaths.

As compared with August, there was a large increase in the admissions of persons affected with scarlet fever and typhoid fever. About the same number of patients suffering from measles and typhus fever were admitted.

	Four Weeks, Sept., 1880.	Five Weeks, Sept., 1881.	Four Weeks, Sept., 1882.
Death-rate from all causes per 1,000 persons living	38·5	21·24	27·3
No. of deaths caused by whooping cough ...	27	0	6
No. of deaths caused by small-pox ...	4	0	0
No. of deaths caused by measles ...	24	4	4
No. of deaths caused by scarlet fever ...	33	8	1
Deaths from typhus do. ...	14	3	6
Do. by typhoid do. ...		10	4
Do. by simple con- tinued do. ...		2	1
Deaths by diarrhoea ...	117	18	40 (a)
Do. by diphtheria ...	4	2	4
Total ...	223	47	66

The rate of mortality was higher than that which prevailed in any month since May. It was 5·63 per 1,000 in excess of the death-rate in September, 1881, but was 9·2 per 1,000 lower than the rate in September, 1880. The zymotic death rate was below the average of the rate in the corresponding period during the last ten years.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

(Continued).

Dr. JACOB'S examination continued.

643. May I ask how you applied that influence to have

an Act of Parliament passed?—In the case of the Public Health Act, for instance, we appeared here before a Committee of the House.

644. Take the Act of 1869, which makes a special exception in favour of Poor-law medical officers to this effect, that a board of guardians may grant superannuation to medical officers, even where their time has not been wholly devoted to the service of the union; you are aware that that applies to no other officers but medical officers?—Yes; but the medical officers were the only exception at that time.

645. Were you on the Executive Committee of the Irish Medical Association at that time, in 1869?—Yes, I was.

646. I presume that the Irish Medical Association had considerable weight in bringing about the passing of the Superannuation Act of that date?—Yes.

647. Might I ask to whom they made their representations?—To Members of the House and Members of the Government at the time. Dr. Darby, of Bray, and others, came over here for the purpose of exercising the usual influence.

648. It is also the fact, is it not, that one of the three members of the Local Government Board of Ireland is a doctor?—Yes.

649. Are you acquainted with the gentleman now holding that office?—Yes; it is Dr. Croker King at present.

650. Were your society consulted with regard to any of the clauses of the present Bill by the officials in Ireland?—I cannot say that we were consulted, but we made representations to the Local Government Board.

651. Did you advise with the Local Government Board on that Bill?—We laid our views before them in the strongest possible terms.

652. I assume that the medical officers object very strongly to the boards of guardians having the power to grant superannuations, and prefer that the initiative should lie with the Local Government Board?—We have always considered it immaterial to us whether the Local Government Board or the boards of guardians had the doing of it, so long as it was compulsory. In point of fact, our original proposition was that the boards of guardians should have the doing of it.

653. My point is this, that, as between the guardians and the Local Government Board, your Association prefers the Local Government Board?—No; the plan that we go for is that the board of guardians shall grant the superannuation compulsorily; that they shall be obliged to do so.

654. You are in favour of compulsion; so that it is not the guardians, who grant it at all if it is compulsory; the Act of Parliament and the action of the guardians is entirely *nil*. But, as between the plan for giving the guardians the option, or the Local Government Board which is your Association in favour of?—If there is to be

an option in the matter, we would much rather have it with the Local Government Board.

655. And you base your reasons for that upon the refusals of the guardians to grant superannuation?—Exactly.

656. And upon no other reasons?—Upon no other reasons, but simply because we consider that the question of the superannuation of a medical officer by the guardians is encumbered with many other considerations than his fitness for office and for the discharge of the duty; whereas in the case of the Local Government Board we suppose that their reasons would be more strictly confined to the good discharge of his duty.

669. It is complained that boards of guardians have not done their duty to medical officers in point of pension; are you aware that out of the total number of pensions now granted, amounting to £13,672, which now falls as a charge upon the rates, the doctors get one-half to themselves, although the doctors are only a small proportion of the entire union officers?—I take it that your figures are correct, but I cannot speak of my own knowledge.

670. There are 101 doctors who get in gross £6,834 of pensions, and there are 264 other officers of all kinds who only get £6,842; so that the 101 doctors get within £8 as much as the 264 other officers of all descriptions; and whereas the average pension to all the other officers is only £26 a year, the doctors get, on an average, £68 a year?—Yes; but they are very superior officers; the numbers that make up the 264 represent non-medical persons, and they are many of them nurses and porters, and persons of that class, on very small salaries; so that, although their numerical importance may be very great, the total of their salaries, if they were taken, would not reach those medical officers. I wish to state, in that connection, that 189 pensions were made (under Mr. Meldon's Return) to medical officers between the years 1867 and 1880; that represents 16 per annum, which, out of 1,000 medical officers, represents one and a-half per cent. of the whole; so that only one and a-half per cent. of the whole of this large number of medical officers ventured to ask for pensions; and that fact alone shows that a great number of persons refrained from asking what they might reasonably be expected to have asked.

671. Mr. Biggar. Do you not know it to be a fact, that in the dispensary districts the ordinary custom is for a young dispensary doctor to get into the dispensary appointment, and only to hold it for a very few years, until he gets into general practice, and that he does not resign either from incapacity, from old age, or ill health, or any other cause of that sort?—No, it is not generally so. In large towns, of course, a man will give his dispensary district up as soon as his professional avocations become so remunerative and engrossing as to enable him to do so; I suppose that observation applies equally to Dublin, Belfast, and anywhere else.

672. Mr. Healy. You think, then, that the comparatively large poundage of the pensions to doctors, as compared with other officials, is on account of the larger salaries of the higher class officials; how then do you account for the fact, whilst I suppose the doctors, as compared with other officers of all kinds, must be in the proportion of one-sixth?—No, it is not so; if you take in all the out-lying dispensary districts of a union, the doctors from a very considerable proportion of the entire number of union officers, I cannot exactly say what the proportion is; but an average union will have, let us say, six dispensary districts attached, and that will mean six medical officers, besides the workhouse medical officers. I should think there would be about an average of eight medical officers attached to each union.

673. How many other officers?—I could not answer the question as to the other officers; I should think if there were 23 or 24 others that might be about it, but that would be a mere guess.

674. Would you say three times as many non-medical officers as medical?—Yes, about that.

675. Then the 101 doctors have got pensions, whereas 264 other officers—that is, one-third of the entire number who have managed to secure pensions, although they complain of the boards of guardians more than any other class of officials—more than the 264 other officers of all kinds, so that there cannot be any especial disability laboured under by the doctors, because they seem to have come off better with regard to pensions than any other class of officers, both in point of numbers and in point of salaries?—As to the statistical question, I could not answer definitely without going into the figures more closely; but I contend that the other officers have suffered very much, too, and therefore the comparison between them and the doctors rather establishes the case of the medical men.

676. What is the average of the salaries that the doctors get from their other duties outside the union—that is to say, from private practice?—That depends solely on the circumstances of the district.

677. Speaking roughly, what would you say?—Taking an average country district in Ireland, if a man makes £150 or £200 in addition to his professional emoluments, he is considered well off; but that can be only taken as an average, because there are districts in which men do not make £250, and other districts in which they make more.

678. Would you say half from salary and half from private sources?—Yes, it might be so.

679. Is it not the case that the other officers, to a large extent, are debarred from holding any other office, but if they do, they are debarred from pension; whereas there is a special Act giving the doctors a right of pension, although their whole time is not taken up with the duties of their office?—On the contrary, other officers—for instance, the clerks of the unions—do hold a variety of offices, and they are not debarred from pension.

680. If the clerk of a union holds any other office, is he not thereby debarred from a pension?—If he gets a pension at all, he gets it in respect of those offices.

681. My question is, Supposing the clerk of a union does other business—supposing he is a solicitor—can he be superannuated?—I speak of the offices which he holds in connection with the clerkship.

682. Supposing the clerk of a union did other work besides other work, does it not debar him from a pension?—No, I think not. I think, so far as I know, the clerk of the union might be a farmer, and he would receive a pension notwithstanding.

683. The Act says that his "whole time" must be devoted to the service of the union?—I imagine that that is an elastic phrase in some cases.

684. If it is elastic, how is it that your body had to get an Act of Parliament which states that the "whole time" of a doctor need not be devoted to the union; surely the 1865 Act must be carried out strictly?—The reason why that Act was got was, because the original Act confined superannuation to those whose whole time was devoted to their duties, and it was held to mean persons who remained in their offices in the transaction of union business from morning to night; and that Act which you hold in your hand was got so as to include medical officers who, although their whole time was at the disposal of the union, did not necessarily give the whole of their time to the union.

685. And, therefore, the medical officers not only are able to double their salary from external sources, but, in addition, they are relieved from the disability which lies upon other officers; they are able to get a pension, although their whole time has not been devoted to their duties; is not that a correct statement of the case?—Yes; they are relieved of this disability so far that they are able to pursue private practice.

686. You have used the phrase that medical officers are

"willing to surrender" something with regard to pensions, in order to get a pension secured to them on the Civil Service scale; what is it that they surrender?—They surrender the right of obtaining a possible superannuation after a short period of service, amounting to full two-thirds of their emoluments. At the present moment a poor-law medical officer might go out of office a fortnight after his appointment; and if the boards of guardians wish it they could give him the full two-thirds; but under the proposed Bill now before Committee, it would be impossible for him to have his two-thirds, or any pension until he has fulfilled a certain period of service. Assuming the grant of the pension according to the Civil Service scale, the poor-law medical officers, if the Bill that is now before Committee should pass, would lose that which they might have, that is, two-thirds of their emoluments and salary after a limited period of service; but they would gain the certainty of having it after a certain period.

687. You appear to be under the impression that the present Bill is compulsory?—No; but I say that the Bill that we strongly advocate would be a compulsory one.

688. Mr. Meldon. My question was, if it was made compulsory, would they give up their present right?—Yes.

689. Mr. Healy. You mentioned a hard case in which a board of guardians, after having granted a man a pension, withdrew it, because the charge fell upon the local district union; but I think it came out afterwards that that was as far back as 1872?—According to the explanation given by Mr. Robinson to-day, it must have been previous to that, but it was mentioned in Mr. Meldon's return as one of the cases.

690. Then a case like that could not again rise?—No; it could not again rise.

691. With reference to the 6th clause of this Bill, which enables the Local Government Board to add a certain number of years to make provision for cases of professional qualification, that does not apply to any other than medical officers' class?—It would apply to medical officers, certainly; it might include others, but it would certainly apply to medical officers.

692. Then I may take that that is a clause more largely in the interests of the medical officers than of many other officers?—That would altogether depend upon the interpretation which was put upon the words of the clause as to what officers it would include, but certainly it would include medical officers, because it speaks of professional services and professional qualifications.

693. The Local Government Board are empowered to add any number of years, not exceeding 10 years, to their service, thereby increasing their nominal service by 10 years?—Yes.

694. And your Association recommends 20?—Yes.

695. On what grounds?—We say, if you take away from us the present privilege that we have of getting two-thirds after a short period of service; if you make us Civil servants, and thereby limit our allowances, you should go to the full length of the Civil Service Act, and 20 years is the term in the Civil Service Act, Dr. Playfair's Act. According to the Playfair Act, 20 years is the period of service allowed to be added to a professional man's service in the computation of his pension. We do not see any reason why poor law medical officers should be placed in a different position from any other Civil servants if this Bill should pass.

696. Could you give us another instance in which this alleged Civil Service scale has been put in operation?—I have given instances in which the scale, as now existing under the Local Government Board, is not in conformity with the Playfair Act.

697. I think you heard the evidence of Mr. Robinson yesterday, in which he admitted that, in point of years, and in point of salary, and in point of compulsion, there was also a departure from the Civil Service Act?—Yes; in the Bill as at present before the Committee.

698. Might I ask how much of the Civil Service scheme is really in this Bill?—If the Bill should eventually remove the words "not exceeding," and substitute "of," and if it should eventually substitute 20 years for 10 years in the clause to which you have just referred, then it would be in conformity with the Civil Service Act.

699. In point of form, it will; but seeing that the Civil servants can join at 21, whereas it is well known that nobody would give a nurse or a medical man or a clerk an office at that age, and that they are generally persons of more mature age, the Civil Service scale cannot be supposed to be a suitable one?—There might be practical hardships in applying the Civil Service scale; nevertheless the poor-law medical officers are so earnest in the matter of getting security that they are prepared to sacrifice these smaller points, and to take the Civil Service scale if it is granted to them.

700. And also, in point of salary, the parity of the Civil Service is not established, because the average Civil servant's salary, as I understand it, is a much greater salary than the average poor-law officer's salary?—Yes.

701. For instance, if a member of your association pass an examination for a medical officer in the Indian Civil Service, or for any other Civil Service appointment, he would be able to get a much greater salary than he gets under the Irish Local Government Board from the boards of guardians?—Yes; but in that case he would be whole time officer, so that we could not reasonably claim on those grounds.

702. Do you think that, under all the circumstances, the conditions of the medical officers and other officers in Ireland correspond with those of the Civil servants in England to such an extent that it is desirable the Civil Service scale should be put in operation in Ireland as the best that could be adopted?—I would not be prepared to say that it is the best, but it is a scale which is fairly applicable, and of which there has been the fullest experience, and it seems to us to come nearly to what would be a fair and practicable scale; and therefore we desire the application of it to the poor law medical officers.

703. The Civil Service scale contemplates an officer beginning at 20 and going on to 60; that is to say, it contemplates 40 years' service?—Yes.

704. Is it your experience that the officers of Irish unions in one case out of 20 have 40 years' service?—There is a considerable per-centage of men who go the whole 40 years; I should say more than one out of 20, decidedly.

705. Would there be one out of 10?—I think that you would be making an excessive estimate if you said that one-tenth go 40 years.

706. Have you any experience at all with regard to Civil servants?—I have a little memorandum on that point. The retirement age of medical officers is much higher than that of Civil servants generally, although owing to the arduous nature of their work they ought to retire much earlier. I find that 89 non-medical professional Civil servants taken at random from the superannuation lists retired on an average at the age of 60, whilst 84 medical officers did not on an average retire until they had reached 66·2, so that there is an excess of age in the case of the medical officers of 6·2 years, comparing the two classes.

707. Are you able to bring out a similar average age of retirement as well as average age of service?—On the question of service, I am not able to speak.

708. But whilst there is the fact of the unlikelihood of the appointment under the Union Officers Act at an earlier age, say, from 26 to 30, the fact that under the Civil Service Regulations it is compulsory to join within much lower limits of age, do you think that an average of 40 years would be a very frequent or possible average?—A professional man would not have to serve 40 years; he would have 10 years or 20 years added in order to reach 40, because he would, according to the

terms of the Bill as it now stands, have 10 years, and according to our contention 20 years added; so that in the case of an officer who has served 30 years, he would be entitled to credit for 40 years in the assessment of his superannuation.

709. Do not you think that instead of having an artificial device and giving the Local Government Board power to add on a number of years to the extent of 10 years, it would be better to change the sixtieths into fiftieths, because you must see that the average number of years is not 40 (inasmuch as 30 counts for 40), if it even reaches 25?—I think that the arrangement would be equally practicable, but that would necessitate the making of a separate scale for non-medical and medical officers, which scale is made in a different way by the clause to which you refer.

710. Then your contention, I gather is, that a medical officer ought to be retired earlier than another officer?—Yes, because his duties require much more youth and physical capacity for their discharge; the duties of a man who has nothing to do but to attend behind a desk, are not comparable to those of a man who has to get up at one or two in the morning, and to drive a carriage across the country to attend a case on the side of a hill; and therefore we say that 10 years or 20 years addition is reasonable, and that it is as good a way of allowing a man to retire at an earlier age as any other way.

711. Instead of adopting the Civil Service scale, which appears, therefore, so unfitted for the union officers in Ireland, do not you think it would be a better plan to fix the number of years' service and say that if a doctor has had 25 years' service, or 20 years, or 15 years, he shall be entitled to apply to the Board for superannuation if unable to do duty?—No; I think taking the cases all round, no scheme that I have heard of will fit the poor law medical officers so satisfactorily as the Civil Service scale.

712. Then, in fact, we may gather that the Civil Service scale is introduced for the benefit of the medical officers in this Bill, and that the other officers throughout Ireland will not be benefited by it to the same extent as the medical officers, for this reason, that there is a clause whereby, after 10 years' service, a man may be pensioned; do you think it likely that any man would get a pension after 10 years' service, except doctors?—The medical officers do not attach great importance to getting pensions earlier in life, or until they are incapable. That is not our object at all, so long as we are assured of good pensions or satisfactory and just pensions when incapable; we do not go for pensions early in life unless in very exceptional cases.

713. If a man got sick after 10 years' duty and got a pension, and then, after a year or two got quite well again and went into his private practice as well as ever, do you think it would be a fair thing to the ratepayers that he should be paid his pension from the rates when he was able to make an income from outside? Yes, I think it would be fair. In the Civil Service, if a man takes his superannuation allowance and goes away and subsequently becomes capable of doing other work, he is at liberty to do that other work; and I do not see why medical officers should be dealt with in a different spirit.

714. Have you read the 5th Clause, which states that any officer who, after being pensioned off, holds any office under the Government or under the Local Government Board can never earn money by taking any other office, whereas doctors have private practices open to them, and might earn a considerable income?—I am not speaking of officers under the Local Government Board; but if the clerk of a union officer, or the master of a workhouse were superannuated for ill-health, and got well at some subsequent period, he could keep a shop, or he could engage on a farm and do a great variety of other things which would not be office under the Local Government Board, or under the Government, and so a medical man might en-

gage in private practice afterwards, and I think it quite right that he should be allowed to do so.

715. You are not in favour of making the limit of age the basis of pension—say 20 years' service and 60 years of age? You are in favour of a graded scale by tenths of sixtieths?—I am in favour of a graded scale by tenths of sixtieths.

716. Sir Patrick O'Brien: The honourable member for Cavan asked you about what was the average salary of the medical officers throughout Ireland, and you said £102 a year, and that, with other sums for minor appointments, made up the amount of £129 a year?—Yes.

717. Most of the appointments which you enumerated were duties in their very nature to be performed by medical men, were they not, such as examination of dangerous lunatics, the position of sanitary officers, and appointments of that kind?—Yes, all of them essentially medical.

718. Asking you not to consider this Bill before the Committee in the nature of a Bill to amend the position of medical and other officers under the poor law, but having regard to paupers in the union, can you tell me whether to your knowledge the medical treatment of paupers throughout Ireland generally, in the Irish workhouses, has suffered by this system of refusing to retire medical officers?—Yes; I believe they have largely suffered.

719. To any considerable extent?—Yes; I say you cannot have 71 persons incapable, or supposed to be incapable by age, in addition to the large number of persons who are probably incapable from ill-health, who pretend to do the duty of dispensary doctors, which duty is physically excessively arduous, without the paupers suffering.

720. And you imagine that men of that age would not be fit to attend cases of night calls?—Yes.

721. You were asked about different unions and divisions of unions in Ireland; your knowledge as editor of this paper makes you very well acquainted with all parts of Ireland?—Yes.

. Are there not districts in Mayo of such an extent as to oblige the medical officer to ride 20 miles upon occasion?—Yes, if a man happens to live on the edge of the district, he may have to ride 20 miles, and there are other districts which include islands on the Atlantic, where a man may ride 15 or 18 miles first and take a boat.

723. And he may not be able to get there at some seasons of the year. In one of the districts in Mayo there are 15 miles included in one dispensary district, are there not?—Yes.

724. Are you able to tell the Committee what are the reasons which have actuated the boards of guardians in Ireland in refusing after a man's resignation to grant him any pension?—The reasons as officially given are in Mr. Meldons's Return in many cases.

725. They are open to us; I do not ask for official reasons, but I ask you as a medical man of experience, and editor of a medical journal, whether it is not a matter of common notoriety in the profession, and in Ireland generally, and I ask your opinion of the reasons which have actuated boards of guardians after the resignation of their medical officers in refusing to grant them any pension?—To be frank, the reason is, that medical officers, for a variety of reasons, do not appear to be popular with their boards of guardians; so many circumstances tend to make them unpopular with boards of guardians; one or other of these circumstances may be the cause of the refusal.

726. Without pursuing that answer, may I ask you, are the reasons of a medical character from inefficiency as a medical officer, which have induced them not to grant a pension?—As a general rule, decidedly not.

subject in connection with accidents attending the use of paraffin lamps. The modification of the old open flashing was adopted in 1879, and the apparatus deposited at the Weights and Measures Department of the Board of Trade. But the reviewer is informed that, after years of careful experiment, the authorities are all at sea, owing to the fact that the flashing point with the same apparatus is quite different in such countries as India from what it is here. The article upon sugar, however, is perhaps the most exhaustive of all, and goes most fully into the subject of polarising saccharometry. The method of detecting the alkaloids will be consulted with profit by our medical readers, as this part of the book is evidently written up to the latest information. We have also a considerable amount about the testing of aniline colours, which certainly cannot be found in any work that we are acquainted with. They are introduced under the head of aniline derivatives.

We have no hesitation in saying that this book is one of the most important that has appeared for some time in connection with analytical chemistry. It contains an amount of observation of an original character which far outweighs the large amount of compilation necessarily required in bringing out such a work.

EXPERIMENTAL CHEMISTRY FOR JUNIOR STUDENTS. (a)

In our review of Part I., issued last year, we spoke in high terms of the introduction to Professor Reynolds' book. Part II. fulfils the expectations raised by the introductory part, and we have very little to add to our previous remarks, except in the form of praise. Part II. is merely an extension, and we may say carries out the experimental plan of instruction laid out in the previous part. Soundness in the rules laid down and simplicity in the illustrative experiments are the marked characteristics of this well-written class-book; it contrasts most favourably with many of the loosely-written works that are now teeming from every teacher of chemistry. Many of the experiments given for class illustration may be said to be original, and well suited for lecture demonstration, or for the student's bench—notably page 188—one to illustrate the luminosity of coal-gas; p. 167, the decomposition of carbon dioxide by magnesium. At page 147 an ingenious method of illustrating the combustion of the diamond is described, which at the same time demonstrates the fact that carbon dioxide is the product of combustion. We think that, as the book is intended for the use of the student, he should be cautioned against trying such experiments as the synthesis of hydrochloric acid from chlorine and hydrogen gas, as described at page 74, in a gas jar. Such an experiment would require considerable care even from the hands of the expert.

As we are dealing with the experiments in this book, we must refer again to Part I., in which some excellent simple illustrations may be found in connection with the subject of the specific heat of metals, and where a description will also be found of an ingenious instrument which the author calls the "atometer." To put it concisely, it is an instrument to measure the increment of heat evolved from atomic weights of different metals (e.g., silver and magnesium) when cooled from 100 C. to a given temperature.

An Appendix is given in Part II., which deals with the systematic testing for the acidulous radicals; now appropriate from one point of view in a book which deals with the non-metallic elements. To commence on the acidulous radicals, it strikes the reviewer as rather impractical for a student who is supposed up to that period to have no knowledge of the separation of the metallic bases. It appears to the writer to be a case where utility is sacrificed to "form" in the construction of the book.

Dr. Reynolds' work is about the best text-book we know for its size, as it is confined to the capabilities of junior students.

Liebig's Extract of Meat.—That a good deal of uncertainty still exists on the question of trade marks as distinctive of medicaments and articles of food and diet is evidenced in a recent number of our contemporary the *Pharmaceutical Journal*, in which the writer shows a curious ignorance in affecting surprise that Dr. Pettenkofer in giving evidence in a recent case respecting the origin of the name "Liebig's Extract of Meat," should have stated on the very best authority, i.e., that of Liebig himself, that

Baron Liebig never claimed to be the inventor of extract of meat generally, but simply the inventor of the special process prescribed by him and followed by the "Liebig's Extract of Meat Company" in preparing their well-known Extract of Meat. Baron Liebig, in the "Annals of Chemistry," vol. lxii. (1847), p. 361, states that Parmentier and Proust, two Frenchmen, recommended the French Government to avail themselves of extract of meat as a medical comfort in campaigns, and expressed their regret that the price at that time should have been so high as to preclude the extract from becoming a general article of consumption. They stated that thirty-two pounds of lean beef were required to make one pound of extract. Thus Baron Liebig admits, and always admitted, that Proust made extract of meat before his time, and he never claimed the inventorship of what in England against his will has been called Liebig's Extract of Meat generally, except in this sense, that he allowed his name exclusively to be appropriated to the extract of the "Liebig Company," manufactured not only by his special process, but under his personal and very strict control. All this has been said and printed many times over, but the writer in the *Pharmaceutical Journal* is much surprised at learning it for the first time. Probably he is not aware of the fact also that the French Courts during the lifetime of Baron Liebig prohibited all other manufacturers of extract of meat calling their extracts in France Liebig's Extract, and condemned several of them to pay damages to the Liebig Company for having used the name of Liebig without authority. In consequence of such judgment the French public are in a better position than the English when buying Liebig's Extract of Meat, as they have the absolute certainty of knowing that they get the article made according to Baron Liebig's special process, and guaranteed genuine by the present Baron Liebig and by Professor Max von Pettenkofer, the present Director of the Scientific Department of the Company, whose reputation is well known throughout the medical and scientific professions of the world. It may be further noted as a curious fact that, notwithstanding the recent legal decision in England against the exclusive use of Liebig's name, the original Company's Extract is almost exclusively demanded by the public, and that though other manufacturers have ornamented their goods with the name of Liebig none have been able to show any substantial success; on the contrary, many sorts offered for sale and advertised at great expense have gradually disappeared from the market, whilst the entire stock of one well-known Australian maker which had taken upwards of thirty pounds of lean beef to produce each pound of extract, was recently sold by auction at 2½d. per pound.

University of London.—The following candidates, who passed the recent Examinations for Honours at this University, have received the degree of M.B. in Medicine:—

FIRST CLASS.

King, D. A., Scholarship & G. M.	Adeney, Edwin Leonard.
Woodridge, L. C., D.Sc. (G. M.)	Wilkinson, W. C., B.A. Sydney
or Harris, Thomas.	Honeyburne, Richard.
Collingwood, David.	Webb, Malcolm.

SECOND CLASS.

{ Buxton, Dudley Wilmot.	{ Fielden, William Eckett.
{ Shaw, Lauriston Elgie.	{ Scharlieb, Mary Ann Dacomb.

THIRD CLASS.

Pratt, Reginald.	{ Dingley, Edward Alfred.
Batterham, John Williams.	{ Shove, Edith.

M.B. in Obstetric Medicine:—

FIRST CLASS.

Scharlieb, M. A. D., Sp. & G. M.	Honeyburne, Richard.
King, David A. (Gold Medal).	

SECOND CLASS.

Shove, Edith.	Harris, Thomas.
Dingley, Edward Alfred.	

M.B. in Forensic Medicine:—

FIRST CLASS.

Wilkinson, W. C., Sp. & G. M.	Woodridge, Leonard Charles.
Webb, Malcolm (Gold Medal).	Currie, Oswald James.
Maddison, William Thomas.	Scharlieb, Mary Ann Dacomb.

SECOND CLASS.

Dingley, Edward Alfred.	King, David Alexander.
Batterham, John Williams.	Vinrace, John Hinks.
Adeney, Edwin Leonard.	

THIRD CLASS.

Honeyburne, Richard.	Collingwood, David.
a Obtained the number of marks qualifying for a Gold Medal.	
N.B.—The bracket indicates equality of merit.	

(a) "Experimental Chemistry for Junior Students." By J. Emerson Reynolds, M.D. London: Longmans, Green & Co. Part II. 1882.

Notices to Correspondents.

MISSING NUMBERS OF THE "DUBLIN MEDICAL JOURNAL."—Five shillings each will be given for the numbers of the *Dublin Journal of Medical Science* for February and March, 1840, if sent to the Dublin Office of this paper, 8 Molesworth Street.

L. E. K.—Any good modern work on materia medica will give you the information you require. The drug is anti-suppurative if given at an early stage of disease. There is only one salt of lime bearing the name sulphide, and its composition is CaS .

DR. RUGG.—We cannot take any action in the matter until the facts are fully and completely laid before us. Nothing will be gained by furthering the necessary information.

DR. WILSON.—A coroner's certificate could alone justify the proceeding. The circumstances under which death occurred, however, are sufficiently doubtful to render full investigation desirable; and you ought to call for it.

PAYMENT OF MEDICAL FEES BY THE POLICE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I should feel much obliged if you would kindly answer the following question—viz.:

J. W. attempted to commit suicide on Wednesday morning. Dr — was sent for by the police and attended J. W. up to the Friday following. Are the police authorities responsible for the payment of the medical attendant for every visit, or only for the first visit? J. W., of course, being a prisoner from the first.

Preston, Lancs.

I remain, yours, &c., M.D.

[*] A medical man called on by the police to visit a patient within a reasonable distance (i.e., where horse hire or train are not necessary) can recover fees from the authorities, but a certificate of attendance should be obtained at the time of the inspector on duty. Three shillings and sixpence each for day, and seven shillings and sixpence each for night visits are generally held to be reasonable by the authorities.—**ED.]**

MR. G. L. TROTMAN.—The West London Medico-Chirurgical Society meets on the first Friday evening in each month. It is about three months old now.

MR. GEORGE SMITH can obtain Southam's "Regional Surgery" through any bookseller, or direct from the publishers, Messrs. J. and A. Churchill. The work has not been reviewed in our columns yet, owing to the pressure on our space. It may, however, be strongly recommended as a most admirable and important guide to the subject.

MR. H. C. B. (Oldham).—The subject cannot be satisfactorily handled in so small a space. We would counsel you to study it more, and to give more time and space, or the results will be disappointing.

SCRIPTIO.—We believe it to be a fact that during the recent Egyptian war a body of soldiers and another of Marines had to make a march of three miles under the burning sun; the soldiers had their tight-fitting jackets, the Marines their loose and free costume. Before the march was ended 130 of the soldiers had fallen out, while every man of the sailors continued in his place. The explanation is simple and feasible, and we see no reason to doubt that the difference was simply one of costume and not of physique.

ANTIDOTES FOR PHOSPHORUS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you allow me to point out to your correspondent "G. S. N." the fact that a simple reference to Section 3021 of the "Medical Digest" would have enabled him to see at a glance all the various antidotes that have been suggested for phosphorus.

Yours obediently,

South Hampstead, Dec. 7th.

RICHARD NEALE, M.D. Lond.

COLLEGE OF PRECEPTORS' EXAMINATIONS.—The Secretary of this College informs us that the entries of candidates for the half-yearly examinations of the College of Preceptors, which began last week, and were carried on simultaneously in London and at fifty-five local centres in various parts of the country, exceeded 8,800, making, with those examined at Midsummer, close upon 13,000 for the year. A supplementary examination, for the preliminary literary subjects required for students of medicine, will be held in March next in London and at four provincial centres—viz., University College, Liverpool; the Leeds Medical School; Queen's College, Birmingham; and University College, Bristol.

MR. G. ALEXANDER (Manchester).—There was an article on the subject to which you refer in our issue for Nov. 22nd, present year.

DR. WILSON (Philadelphia).—We cannot further add to our exchange list, which is already too large.

DR. MATHEWS.—From personal knowledge we consider the climate all that can be desired for phthisical patients. Your experience certainly was unfortunate, but it does not detract from the known fact that a genial and equable temperature usually prevails. All places are of course subject to sudden variations occasionally.

ANTI-PATHETIC.—There is a vast amount of humbug in the pretensions of so called "founders of systems," all of whom have some particular end to serve by forcing new views on the acceptance of the public. You will do wisely to regard them with the utmost suspicion, and to refuse acquiescence in any proposal to join the ranks of a school in opposition to legitimate medicine. As a rule, the founders are but sorry rogues, and their system a miserable fraud. They naturally seek, by any means whatever, to obtain the appearance of support from respectable members of the profession; but such support is accorded after examination of their pretensions has revealed a notorious character.

MEETINGS OF THE SOCIETIES.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 7.30 o'clock Council Meeting.—8 o'clock. Dr. Ormerod, "On Two Cases of Locomotor Ataxy, with Joint Disease."—Mr. R. Clement Lucas, "On Cases of Wounds of Large Vessels."

ROYAL MICROSCOPICAL SOCIETY.—This evening, at 8 o'clock, Ordinary Meeting.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Thursday, Dec. 14th, at 8.30 p.m., Mr. Mules: (1) "On a Case of Hydatid Cyst in Orbit;" (2) "On a Case of Panophthalmitis from Purulent Ophthalmia."—Mr. Lediard, "On a Case of Ivory Exostosis of Orbit."—Mr. Snell, "On a Case of Hard Chancre at Inner Canthus."—Cases of Central Amblyopia in Diabetes, by Mr. Lang, Mr. Lawford, Mr. Stanford Morton, Dr. Edmunds, and Mr. Nettleship.—Living and Card Specimens at 8 o'clock.—Dr. Samuel West. Sequel to a Case of Optic Neuritis: Mr. Gunn, Case showing Peculiar Appearance in the Retina; Dr. Edmunds and Lawford, Optic Nerve from a Case of Diabetes; Dr. Stephen Mackenzie, Drawings showing Extreme Tortuosity of Retinal Vessels.

ACADEMY OF MEDICINE IN IRELAND.—Friday evening Dec. 14th, at 8.30 o'clock, Address by William Moore, Esq., M.D., President of the King and Queen's College of Physicians.—Living Specimens: Mr. Arthur Benson, Case of well marked Retinitis Albuminurica in a boy aged 16, without constitutional disturbance.—Dr. Charles Moore, Case presenting Neuralgic symptoms in a man having remarkable patches of white hair, some of which were congenital.—Card Specimens: Dr. J. W. Moore, Diphtheritic Inflammation of Throat, with Microscopic Sections, shown by Mr. P. S. Abraham.—Papers: Dr. Wallace Beaty, "The Causation of Left Side Pain."—Dr. Richard A. Hayes, "Case of Empyema treated by the Radical Method, with Notes on some Antiseptic Fluids employed."—Dr. Walter G. Smith, "Unilateral Paralysis of the Soft Palate."

Vacancies.

Belfast Royal Hospital.—Ophthalmic Surgeon and a Gynaecologist. Applications must be sent in to the Chairman of the Board of Management not later than Dec. 16th.

Boyle Union, Boyle Dispensary.—Medical Officer. Salary, £170, and £15 as Medical Officer of Health. Election, Dec. 20th.

Castlebar Union, Castlebar Dispensary.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, Dec. 16th.

London Hospital.—Medical and Surgical Registrars. Salary, £100. Applications to be sent to the Hospital not later than Dec. 18th.

Royal Free Hospital, London.—Junior Resident Medical Officer. Board and residence is provided but no salary. (See Advt.)

St. Saviour's Union, Southwark.—Medical Officer for the First District. Salary, £180. Also Vaccination Officer for same district. (See Advt.)

University of Edinburgh.—Examiner in Medicine in each of the Departments of Chemistry, Anatomy, Midwifery, and Practice of Physic. Applications to be forwarded to the Secretary not later than Jan. 15th.

Weston-super-Mare Hospital and Dispensary.—House Surgeon. Salary, £70, with board, &c. Election, Dec. 23rd.

Appointments.

FINN, E., M.B., L.K.Q.C.P.I., L.R.C.S. Ed., Consulting Physician to the North Infirmary, Cork.

GUEST, A., L.R.C.P. Ed., L.F.F.S. Glas., Medical Officer for the Second District of the Chorlton Union.

JESSEY, F. B., F.R.C.S. Eng., Surgeon to the General Dispensary, Bartholomew Close.

LE QUENNE, E. J., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Tring District of the Great Berkhampstead Union.

LLOYD, J. H., L.R.C.P. Ed., M.R.C.S., Medical Officer for the Cul-lompton District of the Tiverton Union.

ROUNDTREE, T. W., M.D., Resident Surgeon and Apothecary to the South Infirmary, Cork.

SPENCE, W. J., L.R.C.P. Ed., L.R.C.S. Ed., House Surgeon to the Bradford Infirmary.

Marriages.

DOWLING-BODKIN.—Dec. 2nd, at the Cathedral, Tuam, John Edward Dowling, M.D., of Dublin, to Ismina Mary, fifth daughter of Thomas Bodkin, M.D., Tuam.

FOYNDER-NISBETT.—Nov. 13th, at Landour, India, Surgeon George F. Foynder, A.M.D., to Mary, second daughter of Major-General J. Nisbett, late Bengal Staff Corps.

Deaths.

CROSS.—Dec. 3rd, at Gillingham, Chatham, Alexander Cross, Deputy Inspector-General of Hospitals and Fleets, aged 77.

DOHERTY.—Nov. 29th, Daniel John Doherty, M.D., Surgeon-Major, late of the 15th Royal Irish, and formerly of the 72nd Highlanders.

DRAZLEY.—Nov. 22nd, at Kelsa, co. Tyrone, Charles Drazley, M.R.C.S., of Milford Haven, aged 64.

HANKS.—Dec. 3rd, at Mile End Road, E., Henry Hanks, L.R.C.P., M.R.C.S., aged 54.

LAWRENCE.—Nov. 30th, at Claverton Street, Bath, Geo. Edgar Lawrence, L.R.C.P. Lond., M.R.C.S., aged 32.

PRICE.—Dec. 6th, at 71A Queen's Road, Peckham, Ann Thomas, widow of Dr. A. F. Price, late of Deptford.

SARJEANT.—Nov. 29th, at Kardley Crescent, West Brompton, Arthur Sarjeant, F.R.C.S., aged 68.

SAVORY.—Dec. 6th, at Wendover, Bucks, Arthur H. Savory, M.R.C.S., L.R.C.P. Edin., aged 34.

WILSON.—Nov. 30th, at Sandown, Isle of Wight, William S. Wilson, L.R.C.P. Lond., M.R.C.S., aged 43.

Notices to Correspondents.

MISSING NUMBERS OF THE "DUBLIN MEDICAL JOURNAL."—Five shillings each will be given for the numbers of the *Dublin Journal of Medical Science* for February and March, 1840, if sent to the Dublin Office of this paper, 8 Molesworth Street.

L. E. K.—Any good modern work on materia medica will give you the information you require. The drug is anti-suppurative if given at an early stage of disease. There is only one salt of lime bearing the name sulphide, and its composition is CaS .

DR. RUGG.—We cannot take any action in the matter until the facts are fully and completely laid before us. Nothing will be gained by withholding the necessary information.

DR. WILSON.—A coroner's certificate could alone justify the proceeding. The circumstances under which death occurred, however, are sufficiently doubtful to render full investigation desirable; and you ought to call for it.

PAYMENT OF MEDICAL FEES BY THE POLICE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I should feel much obliged if you would kindly answer the following question—viz. :—

J. W. attempted to commit suicide on Wednesday morning. Dr. — was sent for by the police and attended J. W. up to the Friday following. Are the police authorities responsible for the payment of the medical attendant for every visit, or only for the first visit? J. W., of course, being a prisoner from the first.

Preston, Lancs.

I remain, yours, &c., M.D.

[*] A medical man called on by the police to visit a patient within a reasonable distance (i.e., where horse hire or train are not necessary) can recover fees from the authorities, but a certificate of attendance should be obtained at the time of the inspector on duty. Three shillings and sixpence each for day, and seven shillings and sixpence each for night visits are generally held to be reasonable by the authorities.—ED.]

MR. G. L. TROTMAN.—The West London Medico-Chirurgical Society meets on the first Friday evening in each month. It is about three months old now.

MR. GEORGE SMITH can obtain Southam's "Regional Surgery" through any bookseller, or direct from the publishers, Messrs. J. and A. Churchill. The work has not been reviewed in our columns yet, owing to the pressure on our space. It may, however, be strongly recommended as a most admirable and important guide to the subject.

MR. E. C. B. (Oldham).—The subject cannot be satisfactorily handled in so small a space. We would counsel you to study it more, and to give more time and space, or the results will be disappointing.

SCORPIC.—We believe it to be a fact that during the recent Egyptian war a body of soldiers and another of Marines had to make a march of three miles under the burning sun; the soldiers had their tight-fitting jackets, the Marines their loose and free costume. Before the march was ended 130 of the soldiers had fallen out, while every man of the sailors continued in his place. The explanation is simple and feasible, and we see no reason to doubt that the difference was simply one of costume and not of physique.

ANTIDOTES FOR PHOSPHORUS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you allow me to point out to your correspondent "G. S. N." the fact that a simple reference to Section 3405 of the "Medical Digest" would have enabled him to see at a glance all the various antidotes that have been suggested for phosphorus.

Yours obediently,

South Hampstead, Dec. 7th.

RICHARD NEALE, M.D. Lond.

COLLEGE OF PRECEPTORS' EXAMINATIONS.—The Secretary of this College informs us that the entries of candidates for the half-yearly examinations of the College of Preceptors, which began last week, and were carried on simultaneously in London and at fifty-five local centres in various parts of the country, exceeded 8,300, making, with those examined at Midsummer, close upon 13,000 for the year. A supplementary examination, for the preliminary literary subjects required for students of medicine, will be held in March next in London and at four provincial centres—viz., University College, Liverpool; the Leeds Medical School; Queen's College, Birmingham; and University College, Bristol.

MR. G. ALEXANDER (Manchester).—There was an article on the subject to which you refer in our issue for Nov. 22nd, present year.

DR. WILSON (Philadelphia).—We cannot further add to our exchange list, which is already too large.

DR. MATHEWS.—From personal knowledge we consider the climate all that can be desired for phthical patients. Your experience certainly was unfortunate, but it does not detract from the known fact that a genial and equable temperature usually prevails. All places are of course subject to sudden variations occasionally.

ANTI-PATHETIC.—There is a vast amount of humbug in the pretensions of so-called "founders of systems," all of whom have some particular end to serve by forcing new views on the acceptance of the public. You will do wisely to regard them with the utmost suspicion, and to refuse acquiescence in any proposal to join the ranks of a school in opposition to legitimate medicine. As a rule, the founders are but sorry rogues, and their system a miserable fraud. They naturally seek, by any means whatever, to obtain the appearance of support from respectable members of the profession; but such support is never accorded after examination of their pretensions has revealed their spurious character.

MEETINGS OF THE SOCIETIES.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 7.30 o'clock Council Meeting.—8 o'clock. Dr. Ormerod, "On Two Cases of Locomotor Ataxy, with Joint Disease."—Mr. R. Clement Lucas, "On Cases of Wounds of Large Vessels."

ROYAL MICROSCOPICAL SOCIETY.—This evening, at 8 o'clock, Ordinary Meeting.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Thursday, Dec. 14th, at 8.30 p.m., Mr. Mules: (1) "On a Case of Hydatid Cyst in Orbit;" (2) "On a Case of Panophthalmitis from Purulent Ophthalmia."—Mr. Lediard, "On a Case of Ivory Exostosis of Orbit."—Mr. Snell, "On a Case of Hard Chancere at Inner Canthus"—Cases of Central Amblyopia in Diabetes, by Mr. Lang, Mr. Lawford, Mr. Stanford Morton, Dr. Edmunds, and Mr. Nettleship.—Living and Card Specimens at 8 o'clock.—Dr. Samuel West, Sequel to a Case of Optic Neuritis: Mr. Gunn, Case showing Peculiar Appearance in the Retina; Dr. Edmunds and Lawford, Optic Nerve from a Case of Diabetes; Dr. Stephen Mackenzie, Drawings showing Extreme Tortuosity of Retinal Vessels.

ACADEMY OF MEDICINE IN IRELAND.—Friday evening Dec. 15th, at 8.30 o'clock, Address by William Moore, Esq., M.D., President of the King and Queen's College of Physicians.—Living Specimens: Mr. Arthur Benson, Case of well marked Retinitis Albuminurica in a boy aged 16, without constitutional disturbance.—Dr. Charles Moore, Case presenting Neuralgic symptoms in a man having remarkable patches of white hair, some of which were congenital.—Card Specimens: Dr. J. W. Moore, Diphtheritic Inflammation of Throat, with Microscopic Sections, shown by Mr. P. S. Abraham.—Papers: Dr. Wallace Beaty, "The Causation of Left Side Pain."—Dr. Richard A. Hayes, "Case of Erysipema treated by the Radical Method, with Notes on some Antiseptic Fluids employed."—Dr. Walter G. Smith, "Unilateral Paralysis of the Soft Palate."

Vacancies.

Belfast Royal Hospital.—Ophthalmic Surgeon and a Gynaecologist. Applications must be sent in to the Chairman of the Board of Management not later than Dec. 16th.

Boyle Union, Boyle Dispensary.—Medical Officer. Salary, £170, and £15 as Medical Officer of Health. Election, Dec. 20th.

fibroid tumour, with extirpa-
tion of the uterus, 418; case of
spina bifida; separation of the
epiphyses of the clavicle by
mu-cular action; six cases of
diphtheria treated by the local
application of borax or boracic
acid, 419; symmetrical conge-
stive mottling of the skin; case
of lumbar nephrectomy for
carcinoma, 461; two cases of
subcutaneous rheumatismal
nodes, 462; three cases of in-
tussusception in infants treated
by abdominal section, 506;
case of acute intussusception,
506

CLINICAL RECORDS.

Uremic convulsions treated with
pilocarpine, Dr. Phillipson, 4;
tetanus, with facial paralysis,
Mr. Hulke, 25; old hydro-
cyst of the liver, cure, Drs.
Oxley and Pollard, 63; restora-
tion of eyelid by transplan-
tation of skin, Mr. A. T. Thom-
son, 90; stricture of urethra,
perineal fistula, Mr. A. T. Nor-
ton, 107; detachment of retina,
Mr. A. T. Thomson, 183, 306;
three cases of acute tuberculo-
sis, Mr. Davies, 280; stone in
the bladder, Mr. Hulke, 328;
genital valgun, Dr. Arnison and
Mr. Page, 350; sebaceous cysts
of the prepuce resembling epi-
thelioma, Dr. Dunlop, 372;
case of fasciculated sarcoma in
Scarpa's triangle of the right
side, Dr. Dunlop, 398; appar-
ent cystitis, renal cysts and
calculi, death, Mr. A. T. Nor-
ton, 437; disarticulation of hip
for sarcoma of the thigh, Mr.
P. J. Hayes, 492; chronic de-
structive arthritis of knee-
joint, excision, cure, Mr. A. T.
Norton, 505; chron suppurative
inflammation of vesiculae
seminales, cystotomy without
relief, death, Mr. A. T. Norton,
